Abstract. Let $f$ be a unimodal map of the interval with critical point $c$. If the orbit of $c$ is not dense then most points in $\lim\downarrow\{[0,1], f\}$ have neighborhoods that are homeomorphic with the product of a Cantor set and an open arc. The points without this property are called inhomogeneities, and the set $I$, of inhomogeneities is equal to $\lim\downarrow\{\omega(c), f|_{\omega(c)}\}$. In this paper we consider the relationship between the limit complexity of $\omega(c)$ and the limit complexity of $I$. We show that if $\omega(c)$ is more complicated than a finite collection of convergent sequences then $I$ can have arbitrarily high limit complexity. We give a complete description of the limit complexity of $I$ for any possible $\omega(c)$.

1. Introduction

Let $f$ be a unimodal map of the interval with critical point $c$. The structure of the inverse limit space generated by $f$ has been the subject of much study, [1], [2], [3]. Recently these spaces have appeared in the study of certain dynamic models from macroeconomics, [16], [15], [13], [14]. A driving problem in the study of such spaces is Ingram’s Conjecture. It states that if $f$ and $g$ are two tent maps with $f \neq g$, then $\lim\downarrow\{[0,1], f\}$ is not homeomorphic to $\lim\downarrow\{[0,1], g\}$. Ingram’s conjecture has been proven in the case that $c$ is periodic, [11], [4], or preperiodic, [5], [21]. It has recently been proven in the case that $c$ is non-recurrent, [20]. One of the distinguishing features among these various cases is the topological structure of the postcritical omega-limit set, $\omega(c)$.

If the orbit of $c$ is not dense in $[0,1]$ then most points in $\lim\downarrow\{[0,1], f\}$ have a neighborhood homeomorphic to the product of a Cantor set and an open arc. The exceptional points without this property we call inhomogeneities and denote the collection of such points by $I$. It
is known that $\mathcal{I} = \lim \{ \omega(c), f|_{\omega(c)} \}$, and hence it is a compact subset of $\lim \{ [0, 1], f \}$. If $c$ has a dense orbit then $\omega(c) = [0, 1]$ and so $\mathcal{I} = \lim \{ [0, 1], f \}$. But it can also be the case that $\mathcal{I}$ is finite, countably infinite, or uncountable (in which case it contains a Cantor set.)

In this paper we consider the case that $\mathcal{I}$ is countably infinite. Then $\mathcal{I}$ and $\omega(c)$ are countably infinite compact sets, and such sets can be topologically identified by their limit complexity or limit height. Roughly speaking, we say that a single isolated point has limit height zero. Then a point which is a limit of a sequence of isolated points (such as 0 in the set \{0\} $\cup \{1/n\}_{n \in \mathbb{N}}$) is said to have limit type 1, and we say that a point which is a limit of points of type 1 is of limit type 2. To see an example of a point of limit type 2, for each $n \in \mathbb{N}$ let $S_n = \{1/n\} \cup \{1/n - 1/j\}_{j > n^2}$ and $S = \{0\} \cup \bigcup_{n \in \mathbb{N}} S_n$. Then $0 \in S$ has limit height 2. We can inductively define limit height $n$ for any $n \in \mathbb{N}$. We can extend the notion to all countable ordinals, $\gamma$, by defining a point to have limit height $\gamma$ provided every neighborhood of the point contains points with limit type $\lambda$ for all $\lambda < \gamma$.

In [7], we prove that the limit height of a countably infinite $\omega$-limit set cannot be a limit ordinal. Then for each allowed countable limit height, $\alpha + 1$, we construct a tent map with postcritical $\omega$-limit set having limit type $\alpha + 1$ and $\mathcal{I}$ also having limit type $\alpha + 1$. As a result of our particular construction techniques in that paper, the limit type of $\mathcal{I}$ and $\omega(c)$ is identical in our examples.

The question we address in this paper is: Given a countable postcritical omega-limit set with $n$ points of highest limit type, $\alpha + 1$, that has a countable inverse limit $\mathcal{I}$ with $m$ points of highest limit type $\beta + 1$, what are the relationships between $\alpha$ and $\beta$ and between $n$ and $m$. We completely answer this question, thus providing a complete picture of the correspondence between $\omega(c)$ and $\mathcal{I} = \lim \{ \omega(c), f|_{\omega(c)} \}$ for i.e.o. unimodal maps when $\mathcal{I}$ is countable. In particular, we show that if $\alpha$ is 0 then so is $\beta$, but if $\alpha \geq 1$ then $\beta$ can be any countable ordinal greater than or equal to $\alpha$.

In Section 2 we briefly mention the symbolic dynamics and kneading theory that we make use of in this paper. Section 3 formally defines what we mean by the limit type of a point and describes the structure of countable compact metric spaces. In this section, we also discuss the notion of a well-founded tree from descriptive set-theory that we use to construct our kneading sequences. Our main theorem is then stated in Section 4.1 whilst the proof is given in Section 5, where we prove the existence of various appropriate unimodal functions by via
their kneading sequences, and in Section , where we discuss the various restrictions on the correspondence between $\omega(c)$ and $I$. We conclude in the final section, by showing that $I$ can be uncountable, even though $\omega(c)$ is countable.

2. Preliminaries

We encourage the reader unfamiliar with techniques from the theory of inverse limit spaces to see [9] or [10].

Let $f : [0, 1] \to [0, 1]$ be continuous. We define the inverse limit of $f$ to be the space 

$$\lim \left\{ [0, 1], f \right\} := \{ x = (x_0, x_1, \ldots) \in [0, 1]^\mathbb{N} : f(x_i) = x_{i-1} \}$$

For each $n \geq 0$ we define $\pi_n : \lim \left\{ [0, 1], f \right\} \to [0, 1]$ to be the $n$th projection map, i.e. $\pi_n(x_0, x_1, \ldots) = x_n$. The standard metric on $\lim \left\{ [0, 1], f \right\}$ we denote by $d$ and it is defined as

$$d(x, y) = \sum_{i=0}^{\infty} \frac{|x_i - y_i|}{2^{i+1}}$$

We say a map, $f$, is locally eventually onto, l.e.o., provided for every $\epsilon > 0$ and for all $x \in [0, 1]$ there is an integer $N$ so that $f^N[B_\epsilon(x)] = [0, 1]$. Let $h$ be a unimodal map of the unit interval with critical point $c_h$. We have shown in [17] & [19] that if $h$ is l.e.o. and $x \in \lim \left\{ [0, 1], h \right\}$ such that $x$ does not have a neighborhood homeomorphic to the product of a Cantor set and an open arc, then every coordinate of $x$ is an element of the omega-limit set of $c_h$, $\omega(c_h) = \bigcap_{n \in \mathbb{N}} \{ h^m(c_h) : m \geq n \}$. Let $I$ denote the set of such points i.e. $I = \lim \left\{ \omega(c), f|_{\omega(c)} \right\}$.

Lemma 2.1. Let $h$ be the core of a tent map with critical point $c_h$ and $\omega(c_h)$ a Cantor set. Then $I$ is also a Cantor set.

Proof. A point $x$ is in $I$ if and only if $\pi_n(x)$ is an element of $\omega(c_h)$ for every $n \in \mathbb{N}$. Let $x \in I$. Let $\epsilon > 0$ and choose $\delta > 0$ and $N \in \mathbb{N}$ so that if $z \in \lim \left\{ [0, 1], h \right\}$ and $\pi_N(z)$ is within $\delta$ of $\pi_N(x)$ then $d(z, x) < \epsilon$. Since $\omega(c_h)$ is a Cantor set there is a point, $z_N \in \omega(c_h)$ such that $|z_N - \pi_N(x)| < \delta$. Since $h[\omega(c_h)] = \omega(c_h)$ it is easy to see that we can construct a point $z \in I$ with $\pi_N(z) = z_N$. Hence $x$ is not isolated in $I$ and $I$ is a Cantor set.

Let $i_h : [0, 1] \to \{0, 1, *\}$ be defined by
For each point \( x \in [0, 1] \) define the itinerary of \( x \) by

\[
I_h(x) = (i_h(x), i_h \circ h(x), i_h \circ h^2(x), \ldots)
\]

and, given an integer \( M \), let the cylinder of diameter \( M \) centered on \( x \) be given by:

\[
I_h(x)|_M = (i_h(x), i_h \circ h(x), i_h \circ h^2(x), \ldots, i_h \circ h^M(x)).
\]

The kneading sequence for \( h \) is defined to be \( K_h = I_h(h(c_h)) \).

The following results are well-known and easy to prove, [6]. Let \( P_h \subseteq [0, 1] \) be the collection of precritical points for \( h \), i.e. the collection of points that have a \(*\) in their itinerary.

**Lemma 2.2.** Let \( h : [0, 1] \to [0, 1] \) be unimodal and l.e.o. and \( \epsilon > 0 \). Then there is an integer \( N \) such that if \( x, y \in [0, 1] \setminus P_h \) and \( I_h(x)|_N = I_h(y)|_N \) then \( |x - y| < \epsilon \).

**Lemma 2.3.** Let \( h : [0, 1] \to [0, 1] \) be unimodal and l.e.o. and choose \( N \in \mathbb{N} \). Then there is an \( \epsilon > 0 \) such that if \( x, y \in [0, 1] \setminus P_h \) and \( |x - y| < \epsilon \) then \( I_h(x)|_N = I_h(y)|_N \).

**Theorem 2.4.** Let \( x, y \in [0, 1] \). Then \( x \in \omega(y) \) if and only if, for every \( N \in \mathbb{N} \), \( I_h(x)|_N \) occurs infinitely often in \( I_h(y) \).

For each point \( x = (x_0, x_1, x_2 \ldots) \) in \( \lim \{ [0, 1], h \} \) define the full itinerary for \( x \) by

\[
\text{Fi}_h(x) = (\ldots, i_h(x_3), i_h(x_2), i_h(x_1), i_h(x_0), i_h \circ h(x_0), i_h \circ h^2(x_0), \ldots)
\]

Notice that if \( h \) is l.e.o. then \( \text{Fi}_h \) is a one-to-one map. Given a bi-infinite sequence \( Z = (\ldots \zeta_{-2}, \zeta_{-1}, \zeta_0, \zeta_1, \zeta_2, \ldots) \) define the shift map by \( \hat{o}(Z) = (\ldots \zeta'_{-2}, \zeta'_{-1}, \zeta'_0, \zeta'_1, \zeta'_2, \ldots) \) where \( \zeta'_i = \zeta_{i-1} \). Define the backwards itinerary for \( x \) by

\[
\text{Fi}_{\hat{o}}(x) = (\ldots, i_h(x_3), i_h(x_2), i_h(x_1))
\]

Given a point \( x \in \lim \{ [0, 1], h \} \) and an integer \( M \) call the string

\[
\text{Fi}_h(x)|_{-M,M} = (i_h(x_M), \ldots, i_h(x_1), i_h(x_0), i_h \circ h(x_0), \ldots, i_h \circ h^M(x_0))
\]
the cylinder of diameter $M$ of $F_i(x)$.

The proofs of the following lemmas are straightforward and can be found in [8] Lemmas 2.5 & 2.6.

**Lemma 2.5.** Let $h : [0, 1] \to [0, 1]$ be l.e.o. and unimodal. Let $\epsilon > 0$. Then there is a positive integer $M$ with the property that if $x, y \in \lim \{[0, 1], h\}$ with $F_i(x)|_{-M,M} = F_i(y)|_{-M,M}$ and neither of $F_i(x)$ and $F_i(y)$ contain $*$ then $d[x, y] < \epsilon$.

**Lemma 2.6.** Let $h : [0, 1] \to [0, 1]$ be l.e.o. and unimodal. Let $M \in \mathbb{N}$. Then there is an $\epsilon > 0$ so that if $x, y \in \lim \{[0, 1], h\}$ with $d[x, y] < \epsilon$ and neither $F_i(x)$ nor $F_i(y)$ contain $*$, then $F_i(x)|_{-M,M} = F_i(y)|_{-M,M}$.

A sequence, $M$, in symbols 0 and 1 is primary provided it is not a $*$-product, i.e. there is no finite word $W$ and sequence $(u_i)_{i \in \mathbb{N}}$ of points from $\{0, 1\}$ with $M = W u_1 W u_2 W u_3 \ldots$. The shift map, $\sigma$, on sequences is defined by $\sigma[(t_0, t_1, \ldots)] = (t_1, t_2, \ldots)$. We order sequences using the parity-lexicographic ordering, $\prec$. To define this order we first define $0 < * < 1$. Let $t = (t_0, t_1, t_2, \ldots)$ and $s = (s_0, s_1, s_2, \ldots)$ be sequences of zeroes and ones. Let $n$ be the least $j$ such that $t_j \neq s_j$. Let $m$ be the number of occurrences of the symbol 1 in the string $(t_0, t_1, \ldots, t_{n-1}) = (s_0, s_1, \ldots, s_{n-1})$. If $m$ is even then define $t < s$ if, and only if, $t_n < s_n$. If $m$ is odd then define $t < s$ if, and only if, $t_n > s_n$. It is easy to show that if $x < y$ then $I_f(x) < I_f(y)$. A sequence, $K$, is shift-maximal provided that for all $j \in \mathbb{N}$, $\sigma^j(K) \prec K$ or $\sigma^j(K) = K$.

The following theorem allows us to construct an infinite sequence of 0’s and 1’s that is the kneading sequence for a tent map core.

**Theorem 2.7.** [6] Lemma III.1.6 Let $K$ be an infinite sequence of 0s and 1s that is shift-maximal, primary and $101^\infty \preceq K$. Then there is a parameter, $q$, in $[\sqrt{2}, 2]$ generating a tent map core, $f_q$, with kneading sequence $K$.

3. Countable Compact Metric Spaces and Limit Types

In this section we briefly describe the structure of compact, countable metric spaces and define what we mean by the limit type or limit complexity. We then define the notion of a well-founded tree, which we use in the construction of our kneading sequences in Section 5.

Let $X$ be any topological space and let $A$ be a subset of $X$. The Cantor-Bendixson derivative, $A'$ of $A$, is the set of all limit points of $A$. Inductively, we can define the iterated Cantor-Bendixson derivatives of
Clearly for some ordinal \( \gamma \), \( X(\gamma) = X(\gamma + 1) \) and \( X \) is said to be scattered if this set is empty and \( X \) is nonempty. In this case, a point of \( X \) has a well-defined Cantor-Bendixson rank, often called the scattered height or limit type of \( x \), defined by \( \text{lt}(x) = \alpha \) if and only if \( x \in X(\alpha) \setminus X(\alpha + 1) \).

The \( \alpha \)th level \( L_\alpha \) of \( X \) (or, more formally, \( L^X_\alpha \)) is then the set of all points of limit type \( \alpha \). Clearly \( L_\alpha \) is the set of isolated points of \( X(\alpha) \).

Since the collection of \( X(\alpha) \)'s forms a decreasing sequence of closed subsets of \( X \), if \( X \) is a compact scattered space, then it has a non-empty finite top level \( X(\gamma) = L_\gamma \).

We endow an ordinal (regarded as the set of its own predecessors) with the interval topology generated by its natural order. With this topology every ordinal is a scattered space.

The standard set-theoretic notation for the first infinite ordinal, i.e. the set of all natural numbers, is \( \omega \). The ordinal \( \omega + 1 \), then, is the set of all ordinals less than or equal to \( \omega \), so \( \omega + 1 \) is the set consisting of \( \omega \) together with all natural numbers. Then \( \omega + 1 \) with its order topology is homeomorphic to the convergent sequence \( S_0 = \{0\} \cup \{1/n : 0 < n \in \mathbb{N}\} \) with the usual topology inherited from the real line. In fact every countable ordinal is homeomorphic to a subset of \( \mathbb{Q} \). The next limit ordinal is \( \omega + \omega = \omega \cdot 2 \). The space \( \omega \cdot 2 + 1 \) consists of all ordinals less than or equal to \( \omega \cdot 2 \), i.e. all natural numbers, \( \omega \), the ordinals \( \omega + n \) for each \( n \in \mathbb{N} \) and the limit ordinal \( \omega \cdot 2 \). The set \( \omega \cdot 2 + 1 \) with its order topology is homeomorphic to two disjoint copies of \( S_0 \). For each \( n \in \mathbb{N} \), the ordinals \( n \) and \( \omega + n \) (0 < \( n \)) have scattered height 0 in. On the other hand, \( \omega \) and \( \omega \cdot 2 \) have scattered height 1, corresponding to the fact that 0 is a limit of isolated points in \( S_0 \) but is not a limit of limit points in \( S_0 \). The ordinal space \( \omega^2 + 1 \) consists of all ordinals less than or equal to \( \omega^2 \) (namely: 0; the successor ordinals \( n \) and \( \omega \cdot n + j \), for each \( j, n \in \mathbb{N} \); the limit ordinals \( \omega \cdot n \), for each \( n \in \mathbb{N} \); and the limit ordinal \( \omega^2 \)). With its natural order topology, \( \omega^2 + 1 \) is homeomorphic to the subset of the real line \( S = \{0\} \cup \bigcup_{n \in \mathbb{N}} S_n \) defined in the Introduction. In this case, the ordinals \( \omega \cdot n \), \( n \in \mathbb{N} \), which have scattered height 1, correspond to the points \( 1/n \), which are limits of isolated points \( 1/n + 1/k \) but not of limit points. The ordinal \( \omega^2 \) has
scattered height 2 and corresponds to the point 0, which is a limit of the limit points 1/n.

In general, the ordinal space \( \omega^\alpha \cdot n + 1 \) consists of \( n \) copies of the space \( \omega^\alpha + 1 \), which itself consist of a single point with limit type \( \alpha \) as well as countably many points of every limit type \( \beta \) with \( \beta < \alpha \). It is a standard topological fact that every countable, compact Hausdorff space \( X \) is not only scattered, but homeomorphic to a countable successor ordinal of the form \( \omega^\alpha \cdot n + 1 \) for some countable ordinal \( \alpha \).

Of course every countable compact metric space is also homeomorphic to a subset of the rationals and, in this context, we can interpret the statement that \( X \simeq \omega^\alpha \cdot n + 1 \) as notation to indicate that \( X \) is homeomorphic to a compact subset of the rationals with \( n \) points of highest limit type \( \alpha \). All such subsets of \( \mathbb{Q} \) are in fact homeomorphic.

We will construct countable postcritical \( \omega \)-limit sets for l.e.o. unimodal maps of the interval with the property that the associated set of inhomogeneities, \( I \), is also countable. In this construction we make extensive use of well-founded trees to construct appropriate kneading sequences, a technique we applied in [7]. For completeness, we briefly describe the construction of a well-founded tree of height \( \alpha \) for each countable ordinal \( \alpha \). Such trees have the remarkable property that they are countable and have finite length branches but can have height \( \alpha \) for any countable ordinal \( \alpha \). For more details we refer the reader to [12, I.2].

Let \( \mathcal{A} \) be a countably infinite set of symbols and let \( \mathcal{A}^{<\mathbb{N}} \) be the set of all finite sequences of elements of \( \mathcal{A} \). Given two elements \( s, t \in \mathcal{A}^{<\mathbb{N}} \) we say that \( t \prec s \) if and only if \( s \) is an initial segment of \( t \), i.e. if and only if \( t = (t_1, t_2, \cdots, t_n) \) and \( s = (t_1, \cdots, t_m) \) for some \( m < n \). If \( n = m + 1 \), then \( t \) extends \( s \) by one symbol and we write \( t \prec s \). If \( s = (s_1, \cdots, s_m) \) and \( t = (t_1, \cdots, t_n) \), then we denote \((s_1, \cdots, s_m, t_1, \cdots, t_n)\) by \( st \).

A subset \( \mathcal{T} \) of \( \mathcal{A}^{<\mathbb{N}} \) is said to be a tree on \( \mathcal{A} \) if it is closed under initial segments, i.e. whenever \( t \in \mathcal{T} \) and, for some \( s \in \mathcal{A}^{<\mathbb{N}} \), \( s \) is an initial segment of \( t \), then \( s \in \mathcal{T} \). Since the null sequence \( \langle \rangle \) is an initial segment of any sequence, \( \langle \rangle \) is the top element of every tree on \( \mathcal{A} \).

An infinite branch in \( \mathcal{T} \) is an infinite sequence \( b = (b_1, b_2, b_3, \cdots) \) of elements from \( \mathcal{A} \) such that \( (b_1, \cdots, b_n) \in \mathcal{T} \) for all \( n \in \mathbb{N} \). If \( \mathcal{T} \) has no infinite branches, then the relation \( \prec \) is well-founded (i.e. has no infinite descending chains) and \( \mathcal{T} \) is said to be a well-founded tree.

We can inductively associate a well-defined ordinal height \( \text{ht}_\mathcal{T}(s) \) to each element \( s \) of a well-founded tree \( \mathcal{T} \) by declaring

\[
\text{ht}_\mathcal{T}(s) = \sup \{ \text{ht}_\mathcal{T}(t) + 1 : t \in \mathcal{T} \text{ and } t \prec s \}
\]
and associate to each well-founded tree $\mathcal{T}$ a well-defined height $Ht(\mathcal{T}) = ht_{\mathcal{T}}(())$. Clearly, if $t < s$, then $ht_{\mathcal{T}}(t) < ht_{\mathcal{T}}(s)$, $ht_{\mathcal{T}}(()) > ht_{\mathcal{T}}(s)$ for any $() \neq s \in \mathcal{T}$ and if $s \in \mathcal{T}$ has maximal length, then $ht_{\mathcal{T}}(s) = 0$.

Trees of height $\alpha$ can be defined recursively. Let $s_a$ be the singleton sequence $(a)$ for some $a \in A$. Obviously $\mathcal{T}_0 = \{\emptyset\}$ is a tree of height 0 on $A$. So suppose that $\alpha = \beta + 1$ and let us assume that there is a tree $\mathcal{T}_\beta$ on $A$ of height $\beta$. Since $A$ is infinite, there is, in fact, a countably infinite family of disjoint trees $\{U_n : n \in \mathbb{N}\}$ each order isomorphic to $\mathcal{T}_\beta$. Define

$$\mathcal{T}_\alpha = \{()\} \cup \{s_a t : t \in U_n, n \in \mathbb{N}\}.$$  

Clearly $\mathcal{T}_\alpha$ is a well-founded tree on $A$. Moreover $ht_{\mathcal{T}_\alpha}(s_a t) = ht_{U_n}(t)$ for every $t \in U_n$ and $n \in \mathbb{N}$, so $Ht(\mathcal{T}_\alpha) = \beta + 1 = \alpha$.

Now suppose that $\alpha$ is a limit ordinal and that for every $\beta < \alpha$ there is a tree $\mathcal{T}_\beta$ of height $\beta$ on $A$. Again, since $A$ is countably infinite, we may assume that $\mathcal{T}_\beta$ and $\mathcal{T}_\gamma$ are disjoint whenever $\beta \neq \gamma < \alpha$. Define

$$\mathcal{T}_\alpha = \{()\} \cup \{s_a t : t \in \mathcal{T}_\beta, \beta < \alpha\}.$$  

Again it is clear that $\mathcal{T}_\alpha$ is a well-founded tree and that $Ht(\mathcal{T}_\alpha) = \alpha$.

Notice that, as constructed, if $t \in \mathcal{T}_\alpha = \mathcal{T}$ for some $\alpha$ and $ht_{\mathcal{T}}(t) = \beta$ then if $\gamma = \beta + 1$, there are infinitely many $s \in \mathcal{T}$ such that $ht_{\mathcal{T}}(s) = \beta$ and $s < t$ and if $\gamma$ is a limit, then for each $\beta < \gamma$, there is some $s < t$ such that $ht_{\mathcal{T}}(s) = \beta$.

4. The Correspondence Theorem

**Theorem 4.1.** Let $f$ be a unimodal, l.e.o. function with critical point $c$, and let $\mathcal{I} = \lim_{\leftarrow}(\omega(c), f|_{\omega(c)})$ be the set of folding points in $\lim_{\leftarrow}([0,1], f)$. Suppose that $\mathcal{I}$ is countably infinite. Then

$$\omega(c) \simeq \omega^{\alpha + 1} \cdot n + 1 \quad \text{and} \quad \mathcal{I} \simeq \omega^{\beta + 1} \cdot m + 1,$$

for some countable ordinals $\alpha \leq \beta$ and natural numbers $n$ and $m$. Moreover

1. If $\alpha = 0$ then $\beta = 0$ and $n = m$.
2. If $1 = \alpha = \beta$ and either:
   - (a) $n = 1$ then $m$ can be any integer $\geq 1$ except 2;
   - (b) $n = 2$ then $m$ can be any integer $\geq 2$ except 4; or
   - (c) $n > 2$ then $m$ can be any integer $\geq n$.
3. If $1 = \alpha < \beta$ and either:
   - (a) $n = 1$ then $m$ can be any integer $\geq 1$ except 2;
   - (b) $n = 2$ then $m$ can be any integer $\geq 2$ except 4;
   - (c) $n = 4$ then $m$ can be any integer $\geq 1$ except 2; or
   - (d) $n \notin \{1, 2, 4\}$ then $m$ can be any integer $\geq 1$. 
(4) If $1 < \alpha = \beta$ and either:
   (a) $n = 1$ then $m$ can be any integer $\geq 1$ except 2;
   (b) $n = 2$ then $m$ can be any integer $\geq 2$ except 4; or
   (c) $n \geq 2$ then $m$ can be any integer $\geq n$.
(5) If $1 < \alpha < \beta$ then $n$ and $m$ can be any positive integers.

It is well known that if $\omega(c)$ is finite then $I \simeq \omega(c)$. [5]. For the first case, $\alpha = 0 = \beta$ and $n = m$ see [18]. The fact that $\alpha$ and $\beta$ are countable and that $m$ and $n$ are finite follows from the discussion of countable compact metric spaces in Section 3. The fact that the power of $\omega$ in each case is a successor ordinal $(\alpha + 1, \beta + 1)$ follows from Theorem 3.3 of [7]. The rest of the proof follows from Theorems 5.1, 5.2, 6.1, 6.2, 6.3, & 6.4.

5. The Constructions

In this section we construct two ‘types’ of kneading sequences, $K$ and $K'$ that will give us Theorems 5.1 & 5.2.

**Theorem 5.1.** Let $1 \leq \beta$ be countable ordinal and $n, m \in \mathbb{N}$. Then there is a unimodal, l.e.o. function $f$ with critical point $c_f$ and kneading sequence $K$ such that $\omega(c_f) \simeq \omega^2 \cdot n + 1$ and $I_f \simeq \omega^{\beta + 1} \cdot m + 1$, in each of the following situations:

1. $1 = \beta$ and either
   (a) $n = 1$ and $m \neq 2$,
   (b) $n = 2$ and $2 \leq m \neq 4$, or
   (c) $2 < n \leq m$.
2. $1 < \beta$ and either
   (a) $n = 1$ and $m \neq 2$,
   (b) $n = 2$ and $2 \leq m \neq 4$,
   (c) $n = 4$ and $m \neq 2$, or
   (d) $n = 3$ or $4 < n$ and $m \in \mathbb{N}$.

**Theorem 5.2.** Let $2 \leq \alpha \leq \beta$ be countable ordinals and $n, m \in \mathbb{N}$. Then there is a unimodal, l.e.o. function $g$ with critical point $c_g$ and kneading sequence $K'$ such that $\omega(c_g) \simeq \omega^{\alpha + 1} \cdot n + 1$ and $I_g \simeq \omega^{\beta + 1} \cdot m + 1$, in each of the following situations:

1. $\alpha = \beta$ and
   (a) $n = 1$ and $m \neq 2$;
   (b) $n = 2$ and $2 \leq m \neq 4$, or;
   (c) $2 < n \leq m$.
2. $\alpha < \beta$.

Before we prove these theorems we detail the construction of the kneading sequences $K$ and $K'$. 
Let $\alpha$ and $\beta$ be countable ordinals such that $1 \leq \alpha \leq \beta$. Let $T_\alpha$ be the countable well-founded $\alpha$ tree constructed as in the previous section and let $\phi_\alpha$ be a bijection from $T_\alpha$ to $\mathbb{E}$, the set of even natural numbers, so that $\phi_\alpha$ labels each node of $T_\alpha$ uniquely with an even natural number. Since every path through $T_\alpha$ is finite, there are countably many paths through $T_\alpha$ of the form $t_n \lessdot t_{n-1} \lessdot \cdots \lessdot t_1 \lessdot ()$ and each of these paths is uniquely identified by its path-labeling, the sequence of even natural numbers $\left(\phi_\alpha(t_1), \ldots, \phi_\alpha(t_n)\right)$. Let $\Lambda$ denote the set of all such sequences of path-labels and index $\Lambda$ as $\{\lambda_i : i \in \mathbb{N}\}$, where $\lambda_i = (\lambda_{i1}, \ldots, \lambda_{im_i})$.

Similarly if $\phi_\beta$ is a bijection from $T_\beta$ to $\mathbb{O}$, the set of odd natural numbers, we obtain a countable collection $\Gamma = \{\gamma_i : i \in \mathbb{N}\}$ of path-labels where $\gamma_i = (\gamma_{i1}, \ldots, \gamma_{im_i})$ and $\gamma_{i1} = \phi_\beta(t)$ for some $t \lessdot () \in T_\beta$.

Let $B$, $U$, $V$ and $W$ be any finite words in 0 and 1 such that each contains at least one 1. Let $A = 10^{r1}$, where $r$ is such that $0^r$ is longer than any string of 0s that can occur in any concatenation of Bs, Us, Vs and Ws.

For each $\gamma_i \in \Gamma$ and $\lambda_i \in \Lambda$, let

\[
V_i = BV_{\lambda_{i1}} BV_{\lambda_{i2}} B \cdots BV_{\lambda_{im_i}} B,
\]

\[
U_i = BU_{\lambda_{i1}} BU_{\lambda_{i2}} B \cdots BU_{\lambda_{im_i}} B,
\]

\[
\hat{U}_i = BU_{\gamma_{im_i}} BU_{\gamma_{im_i-1}} B \cdots BU_{\gamma_{i1}} B
\]

\[
W_i = BW_{\gamma_{im_i}} BW_{\gamma_{im_i-1}} B \cdots BW_{\gamma_{i1}} B
\]

(note that the exponents in the $\hat{U}_i$ and $W_i$ are in the reverse order). Let $\{C_k : k \in \mathbb{N}\}$ list the set $\{U_i : i \in \mathbb{N}\}$ in such a way that each $U_i$ occurs infinitely often and let $\{D_k : k \in \mathbb{N}\}$ list $\{V_i : i \in \mathbb{N}\}$ and $\{E_k : k \in \mathbb{N}\}$ list $\{\hat{U}_i : i \in \mathbb{N}\}$ and $\{F_k : k \in \mathbb{N}\}$ list $\{W_i : i \in \mathbb{N}\}$ in similar fashion. Let

\[
X_k = U^k C_k U^k,
\]

\[
Y_k = V^k D_k V^k,
\]

\[
Z_k = U^k E_k W^k.
\]

\[
X'_k = X_k.
\]

\[
Z'_k = W^k F_k W^k.
\]
We define two kneading sequences of l.e.o. unimodal maps (in fact, they are the kneading sequences of tent maps):

\[ K = AAX_1Y_1Z_1X_2Y_2Z_2X_3Y_3Z_3 \ldots \]
\[ K' = AAX'_1Z'_1X'_2Z'_2X'_3Z'_3 \ldots \]

We begin with a description of the structure of the postcritical omega-limit set and set of inhomogeneities for a tent map, \( f \), with kneading sequence \( K \). Then we give the same information for a tent map, \( g \), with kneading sequence \( K' \). Let \( c_f \) be the critical point for the map \( f \), and let \( \mathcal{I}_f \) be the set of inhomogeneities in \( \lim \rightarrow \{[0, 1], f\} \).

Similarly let \( c_g \) be the critical point for \( g \), and let \( \mathcal{I}_g \) be the set of inhomogeneities for \( \lim \rightarrow \{[0, 1], g\} \).

**Claim 5.3.** The full itineraries that correspond to points in \( \mathcal{I}_f \) are the following and all of their shifts:

1. \( U^Z, V^Z \) and \( W^Z \);
2. \( W^{-\infty}U^\infty, U^{-\infty}V^\infty \) and \( V^{-\infty}U^\infty \);
3. \( U^{-\infty}B^\lambda_1 U^\lambda_2 V B \ldots B U^\lambda_m, B U^\infty \) and \( V^{-\infty}B^\lambda_1 V^\lambda_2 B \ldots B V^\lambda_m, B V^\infty \), for each \( \lambda_i \in \Lambda \), and \( U^{-\infty}B U^\gamma_1 \gamma_2 B \ldots B U^\gamma_m, B W^\infty \), for all \( \gamma_i \in \Gamma \).

**Proof.** The full itineraries of points in \( \mathcal{I}_f \) are exactly those bi-infinite strings for which every central segments occurs infinitely often in \( K \).

Since each \( U_i, V_i \) and \( \hat{U}_i \) occurs infinitely often in the enumeration of the \( C_k, D_k \) and \( E_k \), this means that all full itineraries arise from central segments that occur in the words

\[ W^{k-1}U^k C_k U^k V^k D_k V^k U^k E_k W^k U^{k+1} \]

as \( k \to \infty \).

Clearly the terms \( W^{k-1}U^k, U^k V^k \), and \( V^k U^k \) give rise to \( W^{-\infty}U^\infty, U^{-\infty}V^\infty, V^{-\infty}U^\infty U^Z, V^Z \), and \( W^Z \). Since \( k \to \infty \), any other full itinerary must arise from a subsequence of the terms \( (U^k C_k U^k)_{k \in \mathbb{N}} \) or from a subsequence of \( (V^k D_k V^k)_{k \in \mathbb{N}} \) or from a subsequence of \( (U^k E_k W^k)_{k \in \mathbb{N}} \).

Let us consider the full itineraries that we obtain from the \( (U^k C_k U^k)_{k \in \mathbb{N}} \). Since every path in \( T_\alpha \) is finite, if \( t_n < \cdots < t_1 \) is a maximal path, then there is no \( \lambda \in \Lambda \) which extends the path-label \( (\phi_\alpha(t_1), \ldots, \phi_\alpha(t_n)) \). This implies that the number of times \( B \) occurs in any full itinerary is finite. Suppose that some full itinerary has at least two \( Bs \). Then this full itinerary either has \( BU^p B \) or \( BV^p B \) for some even \( p \) or \( BU^q B \) for
some odd $q$. First suppose we are in the case that the full itinerary contains $BU^pB$ and $p$ is even. Since $\phi_\alpha$ is a bijection onto the set of even integers, this uniquely identifies a node, $t_p$, in the tree $T_\alpha$. Hence there is a path in $T_\alpha$ that contains $t_p$ and has path-label $\lambda_i = (\lambda_{i1}, \lambda_{i2}, \ldots, \lambda_{in_i})$ such that this full itinerary is of the form

$$U^{-\infty} BU^{\lambda_{i1}} BU^{\lambda_{i2}} \ldots BU^{\lambda_{ini}} BU^\infty.$$  

Moreover, for each path-label $\lambda_i = (\lambda_{i1}, \ldots, \lambda_{ini}) \in \Lambda$ we get such a full itinerary. It is clear that the only new full itineraries formed as $i \to \infty$ are $U^{-\infty} BU^\infty$ and $U^Z$.

If instead we are in the case that $BV^pB$ occurs in the full itinerary with $p$ even, an exactly similar argument shows that it is of the form

$$V^{-\infty} BV^{\lambda_{i1}} BV^{\lambda_{i2}} \ldots BV^{\lambda_{ini}} BV^\infty,$$

for some $\lambda_i \in \Lambda$. Then as $i \to \infty$ we get the limit points $V^{-\infty} BV^\infty$ and $V^Z$.

Finally, if we are in the case that $BU^qB$ occurs in the full itinerary with $q$ odd, then since $\phi_\beta$ is a bijection from the tree $T_\beta$ onto the odd integers, this uniquely identifies a node $t_q$ in $T_\beta$. A similar argument shows that the full itinerary is of the form

$$U^{-\infty} BU^{\gamma_{i1}} BU^{\gamma_{i2}} \ldots BU^{\gamma_{imi}} BW^\infty,$$

for some $\gamma_i = (\gamma_{i1}, \ldots, \gamma_{imi}) \in \Gamma$. Again as $i \to \infty$ the limits that occur are $U^{-\infty} BW^\infty$, $U^Z$ and $W^Z$. \hfill \Box

The following claim is now immediate.

**Claim 5.4.** The right itineraries corresponding to points $x \in \omega(cf)$ are the following and all of their shifts:

1. $U^\infty$, $V^\infty$ and $W^\infty$;
2. $W^n U^\infty$, $V^n V^\infty$ and $V^n U^\infty$, for each $n \in \mathbb{N}$;
3. $U^n B U^\infty$, $V^n B V^\infty$ and $U^n B W^\infty$, for each $n \in \mathbb{N}$;
4. (a) $U^n B U^{\lambda_{i1}} BU^{\lambda_{i2}} \ldots BU^{\lambda_{ini}} BU^\infty$, for each $\lambda_i \in \Lambda$, $n \in \mathbb{N}$;
   (b) $V^n B V^{\lambda_{i1}} BV^{\lambda_{i2}} \ldots BV^{\lambda_{ini}} BV^\infty$, for each $\lambda_i \in \Lambda$, $n \in \mathbb{N}$;
   (c) $U^n B U^{\gamma_{i1}} BU^{\gamma_{i2}} \ldots BU^{\gamma_{imi}} BW^\infty$, for each $\gamma_i \in \Gamma$, $n \in \mathbb{N}$.

For finite words $A$ and $B$ we say $A \sim B$ if some shift of $A^Z$ is equal to a shift of $B^Z$.

**Claim 5.5.** $\omega(cf) \simeq \omega^{n+1} \cdot n + 1$ where $n = |U|$ if $U \sim V$ and $n = |U| + |V|$ otherwise.

**Proof.** Notice that the only itineraries of the form $WU^kD$, $UV^kD$, $VV^kD$ and $BW^kD$, for some $D$, are $WU^\infty$, $WU^\infty$, $UV^\infty$, $V^\infty$ and
Therefore, $W^nU$, $U^nV^nV^nU^n$ are isolated for all $n > 0$. Similarly, any word ending $BW^\infty$ is isolated. In particular, 

$$U^nBU^\gamma_{i_{m_i}}BU^\gamma_{i_{n_2}}B\ldots BU^\gamma_{i_{n_1}}BW^\infty$$

is isolated for any $\gamma_i \in \Gamma$ and $n \in \mathbb{N}$.

Every itinerary of the form $W^kD$ is either of the form $W^nU^\infty$ or $W^\infty$. Hence $W^\infty$ has limit type 1.

The itinerary $U^\infty$ is a limit of the sequences $(U^nBU^\infty)_{n \in \mathbb{N}}$ and $(U^nBW^\infty)_{n \in \mathbb{N}}$ and so the limit type of $U^\infty$ is determined by the limit types of the points $U^nBU^\infty$ and $U^nBW^\infty$. Similarly the limit type of $V^\infty$ is determined by the limit types of the points $V^nBV^\infty$.

We claim that for each $n \geq 0$, $U^nBU^\infty$ and $V^nBV^\infty$ have limit type $\alpha$. Since each $U^nBW^\infty$ is isolated, this then implies that $U^\infty$ and $V^\infty$ both have limit type $\alpha + 1$.

So consider $U^nBU^\infty$ for some $n \geq 0$ (the argument for $V^nBV^\infty$ is identical). This is a limit of points of the form (4a) and of points of the form (4c) and their shifts from Claim 5.4. Since points of the form (4c) are all isolated, we only need to consider points of the form (4a) that contain two instances of the word $B$ (since otherwise we are of the form $U^jBU^\infty$). We will show that if $p \in \mathbb{N}$ then the limit type of any point with right itinerary of the form $FBU^pBU^\infty$, for some finite word $F$, is equal to the rank of the node $t_p = \phi_{\alpha}^{-1}(p)$ in the tree $\mathcal{T}_\alpha$. This is enough since node () in the tree $\mathcal{T}_\alpha$ has rank $\alpha$, which then implies that $U^nBU^\infty$ has limit type $\alpha$.

The proof is completed easily by induction. For any $\lambda_{ij}$, let $t_{ij}$ be the node in the tree $\mathcal{T}_\alpha$ such that $\phi_{\alpha}(t_{ij}) = \lambda_{ij}$. Note that the natural number denoted $\lambda_{ij}$ corresponds uniquely to $t_{ij}$ (even though this natural number may be listed as a label in path-labels $\lambda_i$ for different $i \in \mathbb{N}$). Suppose that $t_p = t_{i_{m_i}}$ is a terminal node in $\mathcal{T}_\alpha$, and hence has rank 0. Then no path-label in $\Lambda$ extends the finite sequence $\lambda_i = (\lambda_{i_1}, \ldots, \lambda_{i_{n_i}})$ and so the only point with right itinerary of the form $FBU^{\lambda_{i_{m_i}}BU^rG}$, where $r > 0$ and $G$ is a right infinite word, is $FBU^{\lambda_{i_{m_i}}BU^\infty}$ itself. Hence this point is isolated and has limit type 0. Now suppose that $t_p$ is not a terminal node. Then there is an infinite set $N \subseteq \mathbb{N}$ such that $t_p$ occurs as the penultimate label $t_{i(n_i-1)}$ in the path-label $\lambda_i$ for each $i \in N$. By induction, each point with right itinerary

$$FBU^pBU^{\lambda_{i_{m_i}}BU^\infty} = FBU^{\lambda_{i_{m_i-1}}BU^{\lambda_{i_{m_i}}BU^\infty}}$$

has limit type equal to the rank of $t_{i_{m_i}}$. Since these are precisely the nodes in $\mathcal{T}_\alpha$ that are below $t_p$, the limit type of $FBU^pBU^\infty$ is the same as the rank of $t_p$ and we are done.\]
Claim 5.6. If $\alpha < \beta$, then $I_f \simeq \omega^{\beta+1} \cdot m + 1$, where $m = |U|$ if $U \sim W$ and $m = |U| + |W|$ otherwise. If $\alpha = \beta$, then $I_f \simeq \omega^{\beta+1} \cdot m + 1$ where

$$m = \begin{cases} |U|, & U \sim V \sim W; \\ |U| + |V|, & U \sim W \text{ or } V \sim W; \\ |U| + |W|, & U \sim V \text{ or } W \sim V; \\ |V| + |W|, & V \sim U \text{ or } W \sim U; \\ |U| + |V| + |W|, & \text{otherwise.} \end{cases}$$

Proof. If a full itinerary contains two $B$s then it must contain $BU^p B$, $BV^p B$ for some even integer $p$ or $BU^q B$ for some odd integer $q$. (Recall that we labeled the nodes of the tree $T_\alpha$ with the even integers while we labeled the nodes of the tree $T_\beta$ with odd integers.)

Arguing again by induction, as in the proof of Claim 5.5, one can easily show that for any left infinite word $F$ and even integer $p$, the limit type of both points with full itineraries either $FBU^p BU^\infty$ or $FBV^p BV^\infty$, are both equal to the rank of the node $t_p = \phi_\alpha^{-1}(p)$ in $T_\alpha$. The same is true of any shift of these points. We can also see, by an argument identical to that in the proof of Claim 5.5 that for any right infinite word $F$ and odd integer $q$, the limit type of points with full itinerary $U^\infty BU^q BG$ is equal to the rank of the node $\phi_\alpha^{-1}(q)$ in $T_\beta$.

The points with full itineraries $W^{-\infty}U^\infty$, $U^{-\infty}V^\infty$ and $V^{-\infty}U^\infty$ are all isolated since, for example, no other full itineraries have the form $\ldots WU \ldots$.

Points whose full itinerary is a shift of $V^{-\infty}BV^\infty$ are limits of points with itineraries that are shifts of full itineraries of the form

$$V^{-\infty}BV_{\lambda_1}BV_{\lambda_2}B \ldots BV_{\lambda_m}BV^\infty.$$

Hence points corresponding to shifts of $V^{-\infty}BV^\infty$ have limit type $\alpha$.

Points whose full itinerary is a shift of $U^{-\infty}BW^\infty$ and $V^{-\infty}BU^\infty$ are limits of points with full itineraries that are shifts of

$$U^{-\infty}BU_{\gamma_1}BU_{\gamma_2}B \ldots BU_{\gamma_m}BW^\infty.$$

Hence these points have limit type $\beta$.

It follows then that $V^Z$ has limit type $\alpha + 1$, while $U^Z$ and $W^Z$ both have limit type $\beta + 1$. □

Now we turn our attention to the map $g$ with kneading sequence $K'$. The next four claims follow by arguments similar to the proofs of Claims 5.3, 5.4, 5.5 and 5.6.

Claim 5.7. The full itineraries that correspond to points in $I_g$ are the following and all of their shifts:

(1) $U^Z$ and $W^Z$;

(2) $\ldots U^Z B U^\infty$;

(3) $\ldots W^Z B W^\infty$;

(4) $U^\infty BV^\infty$ and $W^\infty BU^\infty$;

(5) $V^\infty BV^\infty$.
(2) $W^{-\infty} U^{\infty}$ and $U^{-\infty} W^{\infty}$;
(3) $U^{-\infty} B U^{\infty}$ and $W^{-\infty} B W^\infty$;
(4) $U^{-\infty} B U^{\lambda_1} B U^{\lambda_2} B \ldots B U^{\lambda_m} B U^\infty$ for each $\lambda_i \in \Lambda$ and
$W^{-\infty} B W^{\gamma_n} B \ldots B W^{\gamma_2} B W^\infty$, for each $\gamma_i \in \Gamma$.

Claim 5.8. The right itineraries corresponding to points $x \in \omega(c_g)$ are the following and all of their shifts:

1. $U^\infty$ and $W^\infty$;
2. $W^n U^\infty$ and $U^n W^\infty$ for each $n \in \mathbb{N}$;
3. $U^n B U^\infty$ and $W^n B W^\infty$ for each $n \in \mathbb{N}$;
4. $U^n B U^{\lambda_1} B U^{\lambda_2} B \ldots B U^{\lambda_m} B U^\infty$ for each $\lambda_i \in \Lambda$, $n \in \mathbb{N}$ and
$W^n B W^{\gamma_n} B \ldots B W^{\gamma_2} B W^\infty$, for each $\gamma_i \in \Gamma$, $n \in \mathbb{N}$.

Claim 5.9. $\omega(c_g) \simeq \omega^{\alpha+1} |U| + 1$.

Claim 5.10. If $\alpha < \beta$, then $I_g \simeq \omega^{\beta+1} |W| + 1$. If $\alpha = \beta$ then $I_g \simeq \omega^{\beta+1} \cdot m + 1$ where $m = |U|$ if $U \sim W$ and $m = |U| + |W|$ otherwise.

We end this section with proofs of Theorems 5.1 & 5.2.

Proof of 5.1. By careful choice of $U$, $V$, and $W$ in the construction of $K$ outlined above, we obtain a kneading sequence for a tent map $f$ with the properties described in the theorem.

For case (1) we have $\beta = 1$. If $n = 1$ and $m \neq 2$, let $U = V = 1$. If also $m = 1$ then let $W = 1$. If instead $m > 2$, let $W = 01^{m-2}$. Then we see that $\omega(c_f) \simeq \omega^{2} \cdot +1$ and $I_f \simeq \omega^{\beta+1} \cdot m + 1$ by Claims 5.5 & 5.6 proving case (1.a). Similarly when $n = 2$, let $U = V = 01$. If also $m = 2$ then let $W = 01$. If instead $m = 3$ then let $W = 1$. If $4 < m$ then let $W = 01^{m-3}$, which establishes case (1.b). For case (1.c), $2 < n$, let $U = V = 01^{n-1}$. If $m = n$ let $W = U$. Instead suppose that $m > n$. If $m = n + 1$ then let $W = 1$. If $m = n + 2$ then let $W = 01$. If $m > n + 2$ then let $W = 001^{m-n-2}$.

For case (2) let $1 < \beta$. If $n = 1$, let $U = V = 1$. If $m = 1$ then let $W = U$. If instead $m > 2$ then let $W = 01^{m-2}$. This gives case (2.a).

Let $n = 2$ and $U = V = 01$. If $m = 2$ let $W = U$. If $m = 3$ let $W = 1$. If instead $m > 4$ let $W = 01^{m-3}$. This gives case (2.b).

For case (2.c), let $n = 4$. If $m = 1$ let $U = W = 1$ and $V = 011$. If instead $m = 3$ let $U = W = 011$ and $V = 1$. To finish the case, let $U = V = 0111$. If $m = 4$ then let $U = W$. If $m = 5$ let $W = 1$, but if $m = 6$ let $W = 01$. Finally if $m \geq 7$ let $W = 001^{m-n-2}$.

For case (2.d), we start with $n = 3$ and $m \geq n$. Let $U = V = 011$ and if $m = 3$ let $W = U$. If $m = 4$ let $W = 1$. If $m = 5$ let $W = 01$, and if $m > 5$, let $W = 001^{m-5}$. To finish the case that $n = 3$, let $m = 2$. Then chose $U = W = 01$ and $V = 1$. If instead $m = 1$ let
$U = W = 1$ and $V = 01$. Next suppose that $n > 4$ and $m \geq n$. Let $U = V = 001^{n-2}$. If $m = n$ let $U = W$. If $m = n + 1$ let $W = 1$, and if $m \geq n + 2$ let $W = 01^{m-n-1}$. Finally, suppose that $n > 4$ and $m < n$. If $m = 1$ let $U = W = 1$ and $V = 01^{n-4}$. If $m = 2$ let $U = W = 01$ and let $V = 001^{n-2}$. If $m \geq 3$ let $U = W = 001^{m-2}$ and $V = 01^{m-n-1}$.

**Proof of 5.2.** Suppose we are in case (1), $\alpha = \beta$. If $n = 1$ let $U = 1$. If $m = 1$ let $U = W$. If instead $m > 2$ let $W = 01^{m-3}$. Case (1.a) follows by Claims 5.9 & 5.10. For case (1.b), let $n = 2$ and $U = 01$. Then if $m = 2$ let $U = W = 01$, but if $m = 3$ let $W = 1$. If instead $m > 4$ let $W = 01^{m-2}$. To finish case (1), let $2 < n$. Then take $U = 001^{n-2}$, and if $m = n$ let $W = U$. If $m = n + 1$ let $W = 1$, and if $m > n + 1$ let $W = 01^{m-n-1}$.

Next suppose we are in case (2), i.e. $\alpha < \beta$. If $n \geq 3$ then we can chose words $U$ and $W$ with $U \not\sim W$ such that $|U| = n$ and $|W| = m$. This is also true if $m \geq 3$. So suppose that $m, n \leq 2$. If $m = n$ then let $U = V$ is a word with a 1 in it of length $n$. If $m \neq n$ then one of them is 1, without loss of generality, $n = 1$. Then let $U = 1$ and $W = 01$.

**6. Restrictions on the Limit Complexity of the Set of Inhomogeneities**

In this section we show that the cases for which we did not give constructions in the previous section cannot exist. We accomplish this by describing the restrictions on the limit complexity of the set $\mathcal{I}$. In [7], we proved the following theorem which gives a restriction on the limit complexity for any countable $\omega$-limit set and set of inhomogeneities.

**Theorem 6.1.** [7] Let $f$ be a unimodal, l.e.o. function with critical point $c$ such that $\omega(c_f)$ and $\mathcal{I}_f$ are countably infinite. Then there are countable ordinals $\alpha$ and $\beta$ and positive integers $n$ and $m$ such that $\omega(c_f) \simeq \omega^{\alpha+1} \cdot n + 1$ and $\mathcal{I}_f \simeq \omega^{\beta+1} \cdot m + 1$.

We state here the main results for this section.

**Theorem 6.2.** Let $n \in \mathbb{N}$. If $f$ is a unimodal, l.e.o. function with critical point $c$ and $\omega(c) \simeq \omega \cdot n + 1$, then the set of inhomogeneities, $\mathcal{I}$, has $\mathcal{I} \simeq \omega \cdot n + 1$.

**Theorem 6.3.** Let $1 \leq \beta$ be a countable ordinal and $n, m \in \mathbb{N}$. If $f$ is a unimodal, l.e.o. function with critical point $c$ such that $\omega(c_f) \simeq \omega^2 \cdot n + 1$ and $\mathcal{I}_f \simeq \omega^{\beta+1} \cdot m + 1$ then:

1. when $\beta = 1$,
   a) if $n = 1$ then $m \neq 2$,
(b) if $n = 2$ then $2 \leq m \neq 4$, and
(c) if $2 < n$ then $n \leq m$.

(2) when $1 < \beta$,
(a) if $n = 1$ then $m \neq 2$,
(b) if $n = 2$ then $2 \leq m \neq 4$, and
(c) if $n = 4$ then $m \neq 2$.

**Theorem 6.4.** Let $2 \leq \alpha$ and $n, m \in \mathbb{N}$. If $g$ is a unimodal, l.e.o. function with critical point $c_g$ such that $\omega(c_g) \simeq \omega^{\alpha+1} \cdot n + 1$ and $I_g \simeq \omega^{\alpha+1} \cdot m + 1$ then

(1) if $n = 1$ then $m \neq 2$,
(2) if $n = 2$ then $2 \leq m \neq 4$, and
(3) if $2 < n$ then $n \leq m$.

**Lemma 6.5.** Let $n \in \mathbb{N}$. Suppose that $f$ is a unimodal, l.e.o. function with critical point $c_f$. Suppose that $\omega(c_f) \simeq \omega \cdot n + 1$. Then the limit points of $\omega(c_f)$ are periodic.

**Proof.** This follows since $f(\omega(c_f)) = \omega(c_f)$ and $f$ must map these finitely many limit points to themselves (since it is finite-to-one). □

**Proof of 6.2.** We know that $c$ is not recurrent, i.e. $c \notin \omega(c)$, as otherwise $\omega(c)$ would be a Cantor set. Since $f$ is l.e.o., therefore, the itinerary map is a homeomorphism from $\omega(c)$ to its image. Let $W_i, i \leq n$ be a finite word in $\{0, 1\}$ such that the (periodic) limit points of $\omega(c)$ have itinerary of the form $W_i^\infty$ and their shifts.

Let $x \in I$. Then consider the full itinerary of $x$, $Fi(x)$. For each $i \in \mathbb{N}$, let $B_i$ be the itinerary of $x_i = \pi_i(x) \in \omega(c)$. Since $\omega(c)$ is closed, the limit points of $(x_i)_{i \in \mathbb{N}}$ are in $\omega(c)$. Suppose that the $x_i$s converge to more than one point, $x$ and $x'$. Then there are some pair of words $W_i$ and $W_j$ such that the itinerary of $x$ is $W_i^\infty$ and the itinerary of $x'$ is $W_j^\infty$.

Let $(j_n)_{n \in \mathbb{N}}$ and $(i_n)_{n \in \mathbb{N}}$ be defined such that $j_{n+1} < i_{n+1} < j_n < i_n$ for each $n \in \mathbb{N}$ and such that $I(x_{j_n}) = W_j^m \ldots$ and $I(x_{i_n}) = W_i^m \ldots$ where $m_n \to \infty$. Since the sequences $(i_n)_{n \in \mathbb{N}}$ and $(j_n)_{n \in \mathbb{N}}$ are intertwined we see that each $I(x_{j_n}) = W_j^m U_{j_n} V_{j_n} W_i^m \ldots$, where $U_{j_n} \neq W_j$ but $|U_{j_n}| = |W_j|$. Since there are only finitely many possibilities for $U_{j_n}$, there is some $U \neq W_j$ of the same length as $W_j$ and another sequence $(x_{i_n})_{n \in \mathbb{N}}$ with $I(x_{i_n}) = W_j U \ldots$. As $n \to \infty$, the points $x_{i_n}$ converge to a limit point $z$ with itinerary $I(z) = W_j U \ldots$. Clearly $z$ is not periodic which contradicts the fact that it is a limit point. Hence $(x_i)_{i \in \mathbb{N}}$ has a unique limit point $W_i^\infty$, say. This implies that the full itinerary of $x$ is of the form $Fi(x) = \sigma^r(W_i^\infty \cdot V)$ for some $r \in \mathbb{Z}$. By a similar argument using the sequence $(f^i(x))_{i \in \mathbb{N}}$ we see that in fact there is a finite word $U$ with $Fi(x) = \sigma^r(W_i^\infty \cdot UW_j^\infty)$ for some $r \in \mathbb{Z}$ and finite.
word $W_j$ that gives the itinerary of a limit point of $\omega(c)$, where, if $|U| > 0$, then it does not have $W_i$ as an initial segment or $W_j$ as a final segment.

Suppose that for every $m \in \mathbb{N}$ there is a point, $x_m \in I$ with $Fi(x_m) = \sigma^r_m(W_i^{-\infty}U_mW_j^{\infty})$ for some $r_m \in \mathbb{Z}$ and with $|U_m| \geq m$. Then let $(y_m)_{m \in \mathbb{N}} \subseteq \omega(c)$ such that $I(y_m) = U_mW_j^{\infty}$. Let $y \in (y_m)_{m \in \mathbb{N}}$. Then by assumption, $I(y) = W_k^{\infty}$ for some $1 \leq k \leq n$. Since $W_i$ is not an initial segment of $U_m$ we know $k \neq i$. So $Fi(x_m) = \sigma^r_m(W_i^{-\infty}W_k^{t_m}U_mW_j^{\infty})$ for some $r \in \mathbb{Z}$. Hence there is an infinite collection $(z_m)_{m \in \mathbb{N}}$ with $I(z_m) = W_iW_k^{t_m}U_mW_j^{\infty}$. This converges to $W_iW_k^{\infty}$ which is not a limit point for $\omega(c)$, a contradiction. Thus there is some $K$ such that for every $x \in I$ if $Fi(x) = \sigma^r(W_i^{-\infty}.UW_j^{\infty})$ for some $r \in \mathbb{Z}$ then $0 \leq |U| \leq K$.

We next show that $I$ is homeomorphic to $\omega(c)$ by showing that it is a countable collection of isolated points with the same number of limit points as $\omega(c)$. Clearly, for every $x \in I$ with $Fi(x) = \sigma^r(W_i^{-\infty}.W_i^{\infty})$ is a limit of points from $I$. So instead consider $x$ with $Fi(x) = \sigma^r(W_i^{-\infty}.U.W_j^{\infty})$ for some $r \in \mathbb{Z}$ and some $U$ with $0 \leq |U| \leq K$. There are only finitely many choices for $U$ and so all of these countably many points are isolated. Hence $I$ is a finite collection of convergent sequences.

Next we show that if $\omega(c)$ is homeomorphic to some $\omega^{\alpha+1}.n+1$ then $I$ cannot be less complicated then $\omega(c)$. This will follow because the projection map is a continuous surjection and the following proposition.

**Lemma 6.6.** Let $\alpha$ and $\beta$ be countable ordinals, and suppose that $p : \omega^\beta \cdot m+1 \rightarrow \omega^\alpha \cdot n+1$ is a continuous surjection. Then $\alpha \leq \beta$. Moreover, if $\alpha = \beta$ then $m \leq n$.

**Proof.** Since $p$ is continuous, if $z \in \omega^\alpha \cdot n+1$ is an isolated point then $U = \{z\}$ is an open set containing $z$. Hence $p^{-1}(U)$ is open set in $\omega^\beta \cdot m+1$ therefore it contains an isolated point $z'$ which maps to $z$. We continue inductively to prove that if $x \in \omega^\alpha \cdot n+1$ with limit type $\gamma$ then there is a point in the preimage of $x$ that has limit type at least $\gamma$.

Suppose that for all $\lambda < \gamma$ every point in $\omega^\alpha \cdot n+1$ with limit type $\lambda$ has a point in its preimage with limit type at least $\lambda$. Let $z \in \omega^\alpha \cdot n+1$ such that the limit type of $z$ is $\gamma$. Then there is a clopen neighborhood, $U$, of $z$ such that $z$ is the only point in $U$ with limit type $\gamma$ and for any $\lambda < \gamma$ there are infinitely many points in $U$ with limit type $\lambda$. Then $p^{-1}(U)$ is a clopen neighborhood of $p^{-1}(z)$ which contains infinitely many points with limit type at least $\lambda$ for all $\lambda < \gamma$. Hence some point
in $p^{-1}(U)$ has limit type greater than or equal to $\gamma$. Since this is true for all clopen neighborhoods $U$ of $z$ we see that $p^{-1}(z)$ contains a point with limit type $\gamma$. It follows that the points, $v$, with highest limit type in $\omega^\alpha \cdot n + 1$ have a preimage with limit type at least $\alpha$. Hence $\alpha \leq \beta$.

Now suppose that $\alpha = \beta$. Then there are $n$-many points, $v_i$, in $\omega^\alpha \cdot n + 1$ with highest limit type. For each $1 \leq i \leq n$, $p^{-1}(v_i)$ contains a point, $w_i$, with limit type $\alpha$. Thus in $\omega^\beta \cdot m + 1 = \omega^\alpha \cdot m + 1$ we have at least $n$-many points with limit type $\alpha$. Hence $n \leq m$. □

**Lemma 6.7.** Let $f : [0, 1] \to [0, 1]$ be unimodal with critical point $c$. Then if $\alpha$ is a countable ordinal and $\omega(c)$ contains a point with limit type $\alpha$, then $\mathcal{I}$ must contain a point with limit type $\alpha$.

**Proof.** This follows from the previous lemma and the fact that $\pi_1$ is a continuous surjection from $\mathcal{I}$ onto $\omega(c)$. □

The next proposition will imply a restriction on the size of the top level of $\mathcal{I}$.

**Proposition 6.8.** Let $1 \leq \alpha \leq \beta$ be countable ordinals and $n, m \in \mathbb{N}$. Let $f$ be a unimodal, l.e.o. function with critical point $c$. Suppose that $\omega(c) \simeq \omega^{\alpha+1} \cdot n + 1$. Suppose that $\mathcal{I} \simeq \omega^{\beta+1} \cdot m + 1$. Then there is a point $v \in \mathcal{I}$ with limit type $\beta + 1$ such that $\pi_1(v) \in \omega(c)$ has limit type $\gamma \geq 2$.

**Proof.** Consider the finite set of points in $\mathcal{I}$ with limit type $\beta+1$, $L_{\beta+1}$. Since $\sigma$ is a homeomorphism on $\lim\{[0, 1], f\}$ with $\sigma(\mathcal{I}) = \mathcal{I}$, we see that $\sigma(L_{\beta+1}) = L_{\beta+1}$. Hence each point in $L_{\beta+1}$ is a periodic point under $\sigma$. Since $f$ is l.e.o. and unimodal we see that each point in $L_{\beta+1}$ can be represented by a full itinerary of the form $U^\mathbb{Z}$ where $U$ is a finite word.

Let $w \in L_{\beta+1}$. Then there is a sequence $u_n \in L_\beta$ such that $u_n \to w$. Moreover, for each $n$, the sequence $(\sigma^k(u_n))_{k \in \mathbb{Z}}$ has all of its limit points in $L_{\beta+1}$ which is a finite set of periodic points. We claim that this implies that the full itinerary of $u_n$ is $U^{-\infty}BV^\infty$ where $U^\mathbb{Z}$ and $V^\mathbb{Z}$ are each a full itinerary of a point in $L_{\beta+1}$ and $B$ is a finite word (possibly empty). To see this notice that as $k \to -\infty$ there is a subsequence, $(k_i)_{i \in \mathbb{N}}$ such that $\sigma^{k_i}(u_n) \to u \in L_{\beta+1}$ where the full itinerary of $u$ is of the form $U^\mathbb{Z}$ we see that for some finite words, $B_n$ with the property that the first $|U|$ segment of $B_n$ is not $U$, and right-infinite word, $B_0$, and integers $m_n$ the full itinerary of $u_n$ is

$$\ldots U^{m_n} \cdot B_n U^{m_n-1} B_{n-1} \ldots U^{m_1} B_1 B_0$$

or

$$U^{-\infty} B_1 B_0$$
It might be the case that $B_1$ is the empty word. In the first case by considering the shifts of $u_n$ that correspond with
\[ \ldots B_{n+1} U^{m_n} B_n \ldots \]
we get a limit point, $v \in L_{\beta+1}$, of the form $U^{-\infty} B$ where the first $|U|$-length segment of $B$ is not $U$. Now by considering shifts of that word with full itinerary $U^{-\infty} U^N B$ we see that the point $u$ with full itinerary $U^\beta$ is actually a limit point of $L_{\beta+1}$ and hence is in $L_{\beta+2}$. This contradicts the assumption that $\beta + 1$ is the highest limit type in $I$. Thus the full itinerary of $u_n$ is
\[ U^{-\infty} B_1 B_0 \]
where $B_1$ could be empty. By a similar argument for the positive shifts of $u_n$, we see that in fact the full itinerary of $u_n$ is of the form
\[ U^{-\infty} B_1 B_0' V^\infty \]
where $B_0'$ is a finite (perhaps empty) subword of $B_0$ with the property that the last $|V|$-length segment of $B_0'$ is not $V$ if it is non-empty, and the origin could be in between $V$'s $U$s or $B_0'$ and $B_1$. Notice that each $B_0'$ and $B_1$ depends upon the point $u_n$ so there are potentially infinitely many different such words. However if these central words are nonempty and grow with unbounded length in $n$ then they will limit to something in $L_{\beta+1}$. This will lead us to a contradiction as above. Thus there are only finitely many different words $B_1 B_0'$ that are possible. So we lose no generality in assuming that they are all the same, $B$. Then the $u_n$s are just points with full itinerary
\[ U^{-\infty} B V^\infty \]
Since $\beta \geq \alpha \geq 1$ we know that the limit type of $u_n$ is at least 1. So for each $n \in \mathbb{N}$ let $v_{k,n}$ be a sequence of points in $I$ such that $v_{k,n} \to u_n$ as $k \to \infty$. We have the following possibilities for the full itinerary of $v_{k,n}$:

1. $B_k U^N_k B V^\infty$;
2. $B_k U^N_k B V^M_k C_k$;
3. $U^{-\infty} B V^M_k C_k$

where the last $|U|$-length segment of $B_k$ is not $U$ and the first $|V|$-length segment of $C_k$ is not $V$ and $M_k, N_k \to \infty$ as $k \to \infty$.

In cases (2) and (3) we have points in $\omega(c)$ with itinerary $U^N_k B V^M_k C_k$. Fix $n \in \mathbb{N}$. Then for all $M_k \geq n$ we also have a point in $\omega(c)$ with itinerary $U^n B V^M_k C_k$. So as $k \to \infty$ these points converge to a point with limit type at least 1 with itinerary $U^n B V^\infty$. But these converge to a point with limit type at least 2 with itinerary $U^\infty$. Hence there
is a point, \( u \in I \), with limit type \( \beta + 1 \) such that \( \pi_1(u) \) has limit type greater than 1. So suppose that the itineraries of \( v_{n,k} \) satisfy case (1) above.

Now consider the shifts of \( v_{n,k} \) which have full itinerary \( B_n K N_k \ldots \). As \( k \to \infty \), \( B_k \to D \) where the last \( |U| \) length segment of \( D \) is not \( U \).

Thus these shifts of \( v_{n,k} \) converge to some point, \( x \), with full itinerary \( D.U^\infty \) in \( L_\beta \). The previous argument regarding the full itinerary of \( u_n \) holds for any point in \( L_\beta \). Hence either there is some non-empty word \( C \) such that the full itinerary of \( x \) is \( Y^{-\infty}C.U^\infty \), or the full itinerary of \( x \) is of the form \( Y^{-\infty}.U^\infty \) where \( Y.Z \) corresponds to a point in \( L_{\beta + 1} \).

Suppose that the full itinerary of \( x \) is \( Y^{-\infty}C.U^\infty \). Then since \( B_n \to D = Y^{-\infty}C \) for every \( m \in \mathbb{N} \) there is a \( P_m \in \mathbb{N} \) such that for all \( N \geq P_m \),

\[
B_N = B'_N Y^m C
\]

where \( B'_N \neq Y^{-\infty} \). So we see that in fact we have for each \( m \in \mathbb{N} \) infinitely many \( v_{n,k} \)s with full itinerary

\[
B'_N Y^m C U^N_k B V^\infty
\]

Thus for each \( m \) there is an infinite collection of points in \( \omega(c) \) with itinerary \( Y^{-\infty}C.U^N_k B V^\infty \). Then as \( k \to \infty \) we get limit points in \( \omega(c) \) with itinerary \( Y^{-\infty}C.U^\infty \). These points have limit points with itinerary \( Y^\infty \). Since \( Y.Z \) is the full itinerary of a point, \( y \), in \( I \) with limit height \( \beta + 1 \), we see that in this case there is a point, namely \( y \), in \( L_{\beta + 1} \) such that \( \pi_1(y) \) is not limit type 0 or 1.

Suppose instead now that the full itinerary for \( x \) is \( Y^{-\infty}.U^\infty \). Then, again, since \( B_n \to D = Y^{-\infty}C \) for every \( m \) there is a \( P_m \in \mathbb{N} \) such that for all \( N \geq P_m \),

\[
B_N = B'_N D_N Y^m
\]

where \( D_N \neq Y \) but \( |D_N| = |Y| \). So for each \( m \) we have infinitely many \( v_{n,k} \)s with full itinerary

\[
B'_N D_N Y^m U^N_k B V^\infty
\]

If \( Y \neq U \) then we have points in \( \omega(c) \) with itinerary \( Y^m U^N_k B V^\infty \) which converge to limit points with itinerary \( Y^m U^\infty \) which in turn converge to points with itinerary \( Y^\infty \). Again we get a point \( y \in I \) with limit type \( \beta + 1 \) that has the property that \( \pi_1(y) \) does not have limit type 0 or 1 in \( \omega(c) \). If instead though we have \( Y = U \) then since \( |D_N| = |Y| \) without loss of generality we can assume that all of the \( D_N \)s are the same finite word \( D \). By shifting again we see that there is a sequence of points with full itinerary \( B'_N D.U^N_k \ldots \). These converge to a point in \( L_\beta \) with full itinerary \( BD.U^\infty \) where \( D \neq U \) and \( |D| = |U| \). Since this point is in \( L_\beta \) there is some \( Z \) such that \( B = Z^{-\infty}E \). Since \( B'_N \to B \), for every
there is an $m \in \mathbb{N}$ such that for $N \geq P_m$, $B_N' = B_N'' Z^m E$, where $B_N'' \neq Z^{-\infty}$ and $Z^\mathcal{Z}$ is the full itinerary of a point in $L_\beta$. This implies that for every $m$, there are infinitely many $v_{n,k}$s with full itinerary $B_N'' Z^m EDU^{Q_k} BV_\infty$ where $Q_k \to \infty$. This implies that in $\omega(c)$ there are infinitely many points with itinerary $Z^m EDU^{Q_k} BV_\infty$ which limit to points with itinerary $Z^m EDU_\infty$. These points have limit type at least 1 and they limit to points with itinerary $Z^\infty$ which has limit type at least 2. Hence there is a point, $z$, in $\mathcal{I}$ with limit type $\beta + 1$ with the property that the limit type of $\pi_1(z)$ is at least 2.

Proof of 6.3. Since $\omega(c)$ has limit height 2, some point in $\mathcal{I}_f$ with limit type $\beta + 1$ must project into the top level of $\omega(c)$, Proposition 6.8. Notice that there is only one point in $\text{lim} \{(0,1), f\}$ that is fixed by the shift map. This point has full itinerary $1^\mathbb{Z}$. So suppose that $m = 2$. Then we know that the points in $\mathcal{I}_f$ with limit type $\beta$ must be period 2 under $\sigma$. Thus one of them projects to some $x \in \omega(c_f)$ with limit type 2. This point cannot have itinerary $1^\infty$. Thus $n \neq 1$. This establishes cases (1.a) and (2.a).

Similarly, there are only two points in $\text{lim} \{(0,1), f\}$ that have period 2 under $\sigma$. These points have full itinerary $(10)^\mathbb{Z}$ or $(01)^\mathbb{Z}$. Also there are only two points in $[0,1]$ with period 2 under $f$, and they have itinerary $(01)^\infty$ or $(10)^\infty$. Therefore if $m = 4$ then $n \neq 2$. Also if $m = 2$ then $n \neq 4$. Lastly, if $\beta = 1$ then by Lemma 6.6 we see that $m \geq n$. This establishes the remaining cases of the theorem.

Proof of 6.4. Since $\mathcal{I}_g$ and $\omega(c_g)$ have the same limit height, $n \leq m$ by Lemma 6.6. This implies case (3) immediately. By similar reasoning as above if $m = 2$ then $n \neq 1$, and if $m = 4$ then $n \neq 2$.

This completes the proofs of the theorems needed to prove the main theorem of the paper, Theorem 4.1.

7. Countable Postcritical $\omega$-Limit Sets with Uncountable Inverse Limit Spaces

We end the paper with a few examples indicating that $\mathcal{I}_f$ can be much more complicated than $\omega(c_f)$. We outline a construction of maps for which $\omega(c_f)$ has limit type 2 but $\mathcal{I}_f$ is a Cantor set or a Cantor set with a countable collection isolated points.

Consider the full binary tree. We will label the vertices (starting at the 0th level) left to right following the rule that the $j$th vertex in the $n$th level is labeled $2^n + j$ for $0 \leq j < 2^n$. Let $\mathcal{L}$ be the set of all infinite
walks through the labeled tree starting at the first vertex. Notice that \( L \) has uncountably many (actually \( 2^\omega = \mathfrak{c} \) many) points and with the usual topology on \( L \), agreement along initial segments, \( L \) is a Cantor set. Let \( \Gamma \) be the set \( \{(\ldots,\gamma_2,\gamma_1,\gamma_0): (\gamma_0,\gamma_1,\gamma_2\ldots) \in L\} \). Clearly \( \Gamma \) is also a Cantor set.

Let \( B_i = 101^i \) for all \( i \notin \{2^n\}_{n \in \mathbb{N}} \) and let \( B_{2^n} = 1^2^n \) for \( n \in \mathbb{N} \). Let \( A = 10001 \), and let \( (n_i)_{i \in \mathbb{N}} \) be an increasing sequence of positive integers. Let

\[
K = AA1^{n_1}B_11^{n_2}B_2B_11^{n_3}B_3B_11^{n_4}B_4B_2B_11^{n_5}B_5B_2B_11^{n_6}B_6B_3B_1\ldots
\]

where the indices on the strings of \( B_j \)'s follow longer and longer labeled paths backwards through the full binary tree. Clearly \( K \) is the kneading sequence of a tent map \( f \) with critical point \( c \).

**Theorem 7.1.** The point \( x \in \lim\left\{[0,1],f\right\} \) is in \( \mathcal{I}_f \) if, and only if, the full itinerary of \( x \) is a shift of one of the following bi-infinite sequences:

1. \( 1\ldots \)
2. \( B\gamma.1\infty \) for some \( \gamma \in \Gamma \).
3. \( 1^{-\infty}.01\infty \)

Moreover, \( \mathcal{I}_f \) is a Cantor set and \( \omega(c) \simeq \omega^2 + 1 \).

**Proof.** Clearly, all such full itineraries are admissible and correspond to points in \( \mathcal{I}_f \). Now suppose that \( x \in \mathcal{I}_f \). If the full itinerary of \( x \) has fewer than two 0s, then it must satisfy either case (1) or (3). Suppose then that it has two 0s. Since 00 and 010 do not occur infinitely often in \( K \), the full itinerary of \( x \) is

\[
\sigma^r(\ldots1^k01^m.01^j\ldots)
\]

for some \( m \geq 2 \) and \( k, j \geq 1 \) and \( r \geq 0 \). The only way to obtain \( 01^m0 \) from \( K \) is for this to be of the form

\[
\sigma^r(\ldots1^{k-1}B_{m-1}.B_t\ldots)
\]

where \( m - 1, t \) is an allowed path up the binary tree. By construction of \( \Gamma \) we know in fact that we have some \( \gamma \in \Gamma \) which has as its terminal segment \( \gamma_n,\gamma_{n-1},\ldots,\gamma_1 \) where \( \gamma_n = m - 1, \gamma_{n-1} = t \) and \( \gamma_1 = 1 \). So we see that in fact the full itinerary of \( x \) is

\[
\sigma^r(\ldots1^{k-1}B_{\gamma_n}.B_{\gamma_{n-1}}\ldots B_1\ldots)
\]

Since \( n_i \to \infty \) and \( B_1 \) is always followed by some \( 1^{n_i} \) we see that the full itinerary of \( x \) is

\[
\sigma^r(\ldots1^{k-1}B_{\gamma_n}.B_{\gamma_{n-1}}\ldots B_11^{\infty})
\]
It also follows that the string of $B_i$s that can precede $B_\gamma n$ in $K$ will form an infinite path through the labeled tree. Hence if the full itinerary of $x$ contains two 0s then a shift it must satisfy Case (2).

To see that $I_f$ is a Cantor set, we will show that it is a compact set of countably many sub-Cantor sets. Let $C_0 \subseteq I_f$ be the set of points in $I_f$ with full itinerary of the form $B_\gamma 1^\infty$ for some $\gamma \in \Gamma$. This set is clearly homeomorphic with $\Gamma$ which is a Cantor set. Hence for each $r \in \mathbb{Z}$ $C_r = \sigma^r(C_0)$ is also a Cantor set. Thus $I_f$ contains countably many Cantor sets. As $r \to \infty$, $C_r \to z$ with full itinerary $1^{-\infty}$ and as $r \to -\infty$ the limit points of $C_r$ have full itinerary $\sigma^t(1^{-\infty}0.1^\infty)$ for some $t \in \mathbb{Z}$. Hence

$$\bigcup_{r \in \mathbb{Z}} C_r \cup \{z_t\}_{t \in \mathbb{N}} \cup \{z\} = I_f$$

is a Cantor set.

Next we show that $\omega(c)$ is homeomorphic to $\omega^2 + 1$. Notice that by the above argument and Cases (1)–(3) on the set of possible full itineraries, we know that $x \in \omega(c)$ if, and only if its itinerary is a shift of one of the following:

1. $1^\infty$
2. $B_\gamma B_{\gamma_{n-1}} \ldots B_1 1^\infty$ where $\gamma_n, \gamma_{n-1} \ldots \gamma_1$ is a terminal segment of some $\gamma \in \Gamma$.
3. $1^k 01^\infty$ for some $k \in \mathbb{N}$.

Suppose that $x \in \omega(c)$ and its itinerary satisfies Case (2), say

$$\sigma^r(B_\gamma B_{\gamma_{n-1}} \ldots B_1 1^\infty)$$

where $r < |B_\gamma|$ and its itinerary is not degenerately of Case (3), i.e. $n > 2$ and $\gamma_n \neq 2^t$ and $\gamma_n \neq 2^t + 1$ for any $t \geq 0$. Every time $B_\gamma B_{\gamma_{n-1}}$ occurs in $K$ it is followed by $B_{\gamma_{n-2}} B_{\gamma_{n-3}} \ldots B_1 M$ with $M$ increasing. Therefore, there is a unique point in $\omega(c)$ which has $\sigma^r(B_\gamma B_{\gamma_{n-1}} \ldots B_1)$ as an initial segment of its itinerary. It follows then that $x$ is isolated. Clearly, every point $y_t \in \omega(c)$ with itinerary $1^t01^\infty$ is a limit of some sequence of isolated points of Case (2). These all converge to a point $y \in \omega(c)$ with itinerary $1^\infty$.

Notice that we do not need to use the entire binary tree in the above construction. By careful choice of subsets of $\Gamma$ we can follow a modified version of our technique and force the points $z_t \in I_f$ to have any limit type while the points $y_k \in \omega(c)$ have limit type 1. As long as our subset
of $\Gamma$ has an infinite labeled path other than $(1, 2, 2^2, 2^3 \ldots 2^n \ldots)$ the points $y_k$ will have limit type 1 and so the point $y$ will be limit type 2.
