A CLASS OF TWO-DIMENSIONAL AKLT MODELS WITH A GAP

HOUSSAM ABDUL-RAHMAN, MARIUS LEMM, ANGELO LUCIA, BRUNO NACHTERGAELE, AND AMANDA YOUNG

Abstract. The AKLT spin chain is the prototypical example of a frustration-free quantum spin system with a spectral gap above its ground state. Affleck, Kennedy, Lieb, and Tasaki also conjectured that the two-dimensional version of their model on the hexagonal lattice exhibits a spectral gap. In this paper, we introduce a family of variants of the two-dimensional AKLT model depending on a positive integer \( n \), which is defined by decorating the edges of the hexagonal lattice with one-dimensional AKLT spin chains of length \( n \). We prove that these decorated models are gapped for all \( n \geq 3 \).

1. Introduction

A central question concerning a quantum spin system is whether it is gapped or gapless. (We say a system is gapped if its Hamiltonian exhibits a uniform spectral gap above the ground state. Otherwise, it is gapless.) The existence of a spectral gap is known to have wide-ranging consequences for the system’s low energy physics. For instance, the ground states of gapped Hamiltonians display exponential clustering \([21, 35]\) and, in one dimension, they are known to satisfy various notions of bounded complexity \([3, 4, 20, 29]\). Of particular interest are the spin liquid states conjectured to describe a number of interesting two- and three-dimensional systems \([26, 45, 13]\). Moreover, with the advent of Hastings’ spectral flow \([19]\) (also called quasi-adiabatic evolution), it has become possible to explore gapped ground state phases in considerable detail. Different gapped phases are separated from each other by quantum phase transitions, which are accompanied by a closing of the spectral gap \([6, 12]\). Accordingly, numerous recent works are concerned with the stability of the spectral gap under finite-range perturbations assuming local topological order \([12, 31, 32, 36]\). From these considerations, it would be desirable to have a multitude of gapped Hamiltonians that one can use as starting points for further analysis. However, proving the existence of a spectral gap is a non-trivial mathematical task and there exist only limited tools \([15, 16, 22, 27, 30]\) and only a few special models in which a spectral gap has been rigorously established \([2, 5, 7, 9, 10, 11, 27, 30]\), particularly in dimensions \( \geq 2 \). We also mention in passing that deciding whether a general Hamiltonian is gapped or not is known to be undecidable in general, even for reasonable (i.e., translation-invariant and local) Hamiltonians \([3, 14]\). See also \([33]\).

The foundational work in the field was done by Affleck, Kennedy, Lieb and Tasaki (AKLT in the following) in 1988 \([1, 2]\). Motivated by a famous conjecture of Haldane \([17, 18]\) that predicts a spectral gap for the one-dimensional integer-spin Heisenberg antiferromagnet, AKLT provided two main contributions that proved seminal in the years to come:
They defined what is now called the one-dimensional AKLT chain: a spin-1, isotropic (i.e., \(SU(2)\)-invariant) antiferromagnet on a one-dimensional chain. They found that it has a unique ground state in the thermodynamic limit and rigorously established a spectral gap.

They defined analogous spin-\(z/2\) AKLT models on any \(z\)-regular bipartite graph. They focused on the hexagonal lattice case (so spin-3/2) and derived exponential decay of correlations in the infinite-volume ground state. These facts led AKLT to conjecture that the hexagonal model is also gapped.

We make two further remarks about the AKLT model: (a) The ground state of the hexagonal AKLT model was proved to have a unique \([24]\) thermodynamic limit when the limit is taken with boundary conditions in a certain natural class. It is also known that the ground state in finite-volume with periodic boundary conditions (a finite honeycomb lattice wrapped on a torus) is unique \([25]\). Kennedy, Lieb, and Tasaki also proved exponential decay of spin-spin correlations, which is significant because it shows that the AKLT antiferromagnet does not exhibit Néel order, in contrast to its spin-3/2 Heisenberg analog, and that there very likely is a spectral gap above the ground state. (b) Historically, the AKLT chain provided the first example of a Hamiltonian whose ground states are matrix product states. This notion has been vastly generalized, starting with \([15]\), to what are now called tensor network states, and has developed into a central tenet of modern many-body physics \([37, 42]\).

The conjecture of AKLT that the hexagonal AKLT model (or any other AKLT model in dimension \(\geq 2\)) is gapped remains open to this day. This is insofar remarkable as all of the AKLT models share a key feature that makes the spectral gap problem in principle more amenable: They are frustration-free, meaning that the global ground state is also locally energy-minimizing.

In the present work, we introduce a novel family of AKLT models on ‘decorated’ hexagonal lattices depending on an integer parameter \(n\), and prove that these models are gapped for sufficiently large values of \(n\). We call these models the edge-decorated AKLT models (or decorated AKLT models for short). The positive integer \(n\) will be called the decoration number, and we explain its role in the next paragraph.

The decorated AKLT model is defined by replacing each edge of the hexagonal lattice with a copy of the one-dimensional AKLT chain of length \(n\). Notice that this means that there are two types of vertices in the system: vertices of the hexagonal lattice which have degree 3 and spin 3/2, and “internal vertices” of the decorated edges which have degree 2 and spin 1; see Figure 1. The heuristic behind this construction is that the decorated AKLT model incorporates features of the one-dimensional AKLT chain, which is known to be gapped from the work of AKLT. While the decorated model is a bit contrived, it is not unreasonable to expect its ground state(s) to belong to the same gapped phase as those of the original AKLT model on the hexagonal lattice. It seems likely that the same features that generated interest in two-dimensional AKLT models \([38, 40, 43]\) are also present for the decorated AKLT model. In particular, we mention \([44]\), where it was shown that the valence-bond ground states of similarly decorated AKLT models can serve as a universal resource for quantum computation. Going beyond AKLT-type models, an \(SU(3)\) spin liquid with \(Z_3\) topological order has recently been proposed in \([28]\). It too is expected to be gapped.
2. AKLT MODELS ON DECORATED TWO-DIMENSIONAL LATTICES

For concreteness, we will first discuss in detail an AKLT model on a honeycomb lattice with additional spins on the edges. It will then be straightforward to consider generalizations to which the same arguments apply.

Let \( \Gamma \) be the hexagonal lattice and \( n \geq 1 \). The standard AKLT model on \( \Gamma \) [24] has a spin-3/2 degree of freedom at each vertex. For the ‘decorated’ models we introduce here, we add \( n \) spin 1’s along each edge of \( \Gamma \) and call the resulting ‘lattice’ \( \Gamma^{(n)} \). On this graph with both degree 2 and degree 3 vertices (see Figure 1), we define the AKLT Hamiltonian as usual with nearest neighbor interactions given by the orthogonal projection \( P^{(z(e)/2)} \) onto the space of total spin \( z(e)/2 \), where for any edge \( e \), \( z(e) \) is the sum of the degrees of its two vertices. For the AKLT model on \( \Gamma^{(1)} \), all the interaction terms are \( P^{(5/2)} \). For \( n \geq 2 \), the model also has interactions \( P^{(2)} \) between neighboring spin 1’s. This class of models is a special case of the general class of AKLT-type models studied in [25]. There, it is shown that they are frustration-free and also that the ground state is non-degenerate if the model is considered with periodic boundary conditions. The frustration-freeness is easily proved in the same way as for the original AKLT models by using the Valence Bond Solid construction of a non-zero vector in the kernel of the manifestly non-negative Hamiltonian.

Let \( \Lambda \) be a suitable finite subset of \( \Gamma \) considered with periodic boundary conditions and denote by \( \Lambda^{(n)} \) its decoration as above. Let \( \mathcal{E}_{\Lambda^{(n)}} \) denote the set of edges of the decorated
graph and consider the Hamiltonian

\[ H_{\Lambda(n)} = \sum_{e \in \mathcal{E}_{\Lambda(n)}} \Lambda(e) P_{\frac{x}{2}}(z(e)). \]

We claim that for \( n \) large enough there is \( \gamma_n > 0 \) such that for all nice \( \Lambda \) the gap of \( H_{\Lambda(n)} \) is lower bounded by \( \gamma_n \). In this context, ‘nice’ \( \Lambda \), means that one can consider the decorated graph \( \Lambda^{(n)} \) as a union of overlapping subgraphs isomorphic to the H-shaped graph shown in Figure 2. For concreteness, we will explicitly treat the case of periodic boundary conditions (a finite rectangle cut out of the hexagonal lattice and wrapped around a torus). Other shapes can be considered without any significant change in the arguments.

To prove the claim we consider a comparable model defined as follows. For each vertex \( v \) in \( \Lambda \) and the three edges meeting in \( v \), we consider the subsystem consisting of the spin \( \frac{3}{2} \) at \( v \) and the 3 spin 1’s residing on the three edges. Let \( Y_v \) denote the corresponding set of \( 3n + 1 \) vertices in \( \Lambda^{(n)} \) and define \( h_v \) to be the AKLT Hamiltonian on \( Y_v \). Then

\[ H_{\Lambda(n)} \leq \sum_{v \in \Lambda} h_v \leq 2H_{\Lambda(n)}. \]

To simplify things further, define \( P_v \) to be the orthogonal projection onto ran \( h_v \). It is a straightforward calculation to check that \( \ker(P_v) = \ker(h_v) \) is 8-dimensional for \( n = 1 \), and hence for all larger values of \( n \) as well. We will estimate the gap of

\[ \tilde{H}_{\Lambda(n)} = \sum_{v \in \Lambda} P_v, \]

which is also comparable to \( H_{\Lambda(n)} \):

\[ \frac{1}{2} \gamma Y \tilde{H}_{\Lambda(n)} \leq H_{\Lambda(n)} \leq \|h_Y\| \tilde{H}_{\Lambda(n)}, \]

with \( \gamma > 0 \). This inequality implies that \( \tilde{H}_{\Lambda(n)} \) is also frustration-free since \( \ker(\tilde{H}_{\Lambda(n)}) = \ker(H_{\Lambda(n)}) \neq \{0\} \). Therefore, it suffices to study the gap of \( \tilde{H}_{\Lambda(n)} \).

We will obtain a lower bound for the gap of \( \tilde{H}_{\Lambda(n)} \), by finding a constant \( \gamma > 0 \) satisfying

\[ (\tilde{H}_{\Lambda(n)})^2 = \tilde{H}_{\Lambda(n)} + \sum_{\{v,w\} \subset \Lambda, v \neq w} (P_vP_w + P_wP_v) \geq \gamma \tilde{H}_{\Lambda(n)}. \]

If \( v \) and \( w \) are not nearest neighbors, \( P_v \) and \( P_w \) commute and \( P_vP_w + P_wP_v \geq 0 \). Therefore, in the second term we can drop all contributions from such pairs. For the nearest neighbor pairs \( (v,w) \), instead of the combinatorial style argument in [27], which requires good estimates of a specific finite-volume gap, we apply the following inequality for a pair orthogonal projections \( E \) and \( F \) (for a proof see [15, Lemma 6.3]):

\[ EF + FE \geq -\|EF - E \wedge F\|(E + F). \]

Here, \( E \wedge F \) is the orthogonal projection onto ran \( E \cap \text{ran} F \). We need this for \( E = P_v, F = P_w \), with \( v, w \) nearest neighbors in \( \Lambda \).

The norm in (2.6) remains unchanged if we replace \( E \) and \( F \) by \( \mathbb{1} - E \) and \( \mathbb{1} - F \), which, in our application, are the corresponding ground state projections. All nearest neighbor
pairs are equivalent in this consideration and we denote $1 - P_v = P_x$, $1 - P_w = P_z$, and $P_x \wedge P_z = P_{x,z}$. Define
\begin{equation}
\epsilon_n = \|P_x P_z - P_{x,z}\|.
\end{equation}
Since every $v \in \Lambda$ has 3 nearest neighbors, we have shown
\begin{equation}
(\tilde{H}_{\Lambda(n)})^2 \geq (1 - 3\epsilon_n)\tilde{H}_{\Lambda(n)}.
\end{equation}
Therefore,
\begin{equation}
gap(H_{\Lambda(n)}) \geq \frac{1}{2} \gamma (1 - 3\epsilon_n).
\end{equation}
It remains to show that $\epsilon_n < 1/3$.

**Proposition 2.1.** Let

\begin{equation}
A_n = \frac{4}{3^n \left(1 - \frac{8(1 + 3^{-2n-1})}{3^n(1 - 3^{-2n})}\right)}.
\end{equation}

Then, for all $n \geq 3$, the quantity $\epsilon_n$ defined in (2.7) satisfies
\begin{equation}
\epsilon_n \leq A_n + A_n^2 \left(1 + \frac{8(1 + 3^{-2n-1})^2}{3^n(1 - 3^{-2n})^2}\right) < 1/3.
\end{equation}

The proof of this proposition is contained in the next two sections. As a consequence, we can state the following theorem.

**Theorem 2.2.** The spectral gap above the ground state of the AKLT model on the edge-decorated honeycomb lattice with $n \geq 3$ has a strictly positive lower bound uniformly for all finite volumes with periodic boundary conditions.

3. **Ground state projections for subgraphs overlapping on a chain**

To prove Proposition 2.1 we will formulate the quantity $\epsilon_n$ in terms of the ground state projections of quasi-one-dimensional Matrix Product States (MPS). A rather straightforward generalization of the arguments in [15] to MPS systems with matrices that may vary from site to site and are not necessarily square, will then yield the desired estimate. With an eye toward possible further generalizations and applications, we will estimate $\epsilon_n$ in a slightly more general setting, which we now introduce. The role of the finite subgraph $\gamma \times$ of the decorated honeycomb lattice will be played by a finite graph $G$ with a certain structure and we will make a number of assumptions on the ground states of a frustration free Hamiltonian on $G$. In Section 4 we will show that these assumptions are satisfied for the AKLT model on the decorated honeycomb lattice.

3.1. **Assumptions on the tensor network states for the local patch $G$.** Consider a finite graph $G = (V, E)$ of the form $G_L - C_n - G_R$, meaning there are finite graphs $G_L$ and $G_R$, $C_n = [v_1, v_n]$ is a chain of $n$ vertices, and there exist $v_L \in G_L, v_R \in G_R$ such that $V$ is the disjoint union of the vertices of $G_L, C_n$ and $G_R$ and $E$ consists of the edges of $G_L, C_n$ and $G_R$ together with $(v_L, v_1)$ and $(v_n, v_R)$, see Figure 2. We consider a frustration-free Hamiltonian on $G$ of the following form:
\begin{equation}
H_G = H_{G_L} + H_{C_n} + H_{G_R} + h_{v_L,v_1} + h_{v_n,v_R},
\end{equation}
Figure 2. The graph $G$ for the decorated AKLT model.

where $H_{G_L}$, $H_{G_R}$, and $H_{C_n}$ satisfy the following conditions. First, we assume $H_{C_n}$ has ground states given by a translation invariant MPS with a primitive transfer matrix $E$. Let $D$ denote the bond dimension of this MPS and pick an orthonormal basis $\{|i\rangle \mid 1 \leq i \leq d\}$ for the physical degree of freedom at each of the $n$ sites of $C_n$. In this case the transfer matrix $E$, in isometric form, is given in terms of $d D \times D$ matrices $V_i$:

$$\mathbb{E}(B) = \sum_{i=1}^{d} V_i^* B V_i, \quad B \in M_D, \quad \text{with } \mathbb{E}(\mathbb{I}) = \mathbb{I}. \quad (3.2)$$

The primitivity assumption implies that there exists a non-singular density matrix $\rho \in M_D$ satisfying $\mathbb{E}(\rho) = \rho$, and constants $C \geq 0$ and $\lambda \in [0, 1)$, such that

$$\alpha(n) := \|\mathbb{E}^n - |1\rangle \langle 1|\| \leq C \lambda^n. \quad (3.3)$$

For the spin-1 AKLT chain one has this estimate with $C = 1$ and $\lambda = 1/3$, and both constants are sharp in that case.

We now turn to the assumptions we make on $H_{G_L}$ and $H_{G_R}$. For $\bar{z} \in \{L, R\}$, let $\mathcal{H}_{\bar{z}}$ be the Hilbert space associated with the system on $G_{\bar{z}}$. We assume that the ground states of $H_{G_{\bar{z}}}$ are given by a tensor $T_{\bar{z}}$ as follows. We will consider $T_{\bar{z}}$ as a set of $\dim \mathcal{H}_{\bar{z}} D \times D$ matrices labeled by an orthonormal basis $\{|r\rangle_{\bar{z}}\}$ of $\mathcal{H}_{\bar{z}}$. The physical Hilbert space for the system on $G$ is $\mathcal{H}_G = \mathcal{H}_{G_L} \otimes \mathcal{H}_{C_n} \otimes \mathcal{H}_{G_R}$, and the auxiliary space, which parametrizes the ground states, is $\mathcal{K}_G = \mathbb{C}^{D_L} \otimes \mathbb{C}^{D_R}$, which we identify with $\mathcal{L}(\mathbb{C}^{D_L}, \mathbb{C}^{D_R})$ and equip with the standard inner product $\langle \cdot , \cdot \rangle_{\mathcal{K}_G}$. The map $\Gamma_G : \mathcal{K}_G \to \mathcal{H}_G$ is then given by

$$\Gamma_G(B) = \sum_{i_1, \ldots, i_n, r} \text{Tr}[B T_{R}^{i_n} \cdots T_{L}^{i_1} |i\rangle_L \otimes |i_1, \ldots, i_n\rangle \otimes |r\rangle_R], \quad B \in \mathcal{K}_G. \quad (3.4)$$

We assume that $H_G$ is frustration free, which means that all terms in (3.4) are non-negative and $\ker H_G \neq \{0\}$ and, in addition, we assume $\ker H_G = \text{ran} \Gamma_G$.

We also introduce the transfer matrices associated with $G_L$ and $G_R$, $\mathbb{E}_L : M_D \to M_{D_L}$ and $\mathbb{E}_R : M_{D_R} \to M_D$, as follows:

$$\mathbb{E}_L(B) = \sum_l (T^*_l)^* B T^*_l, \quad \mathbb{E}_R(B) = \sum_r (T^*_r)^* B T^*_r. \quad (3.5)$$
and define
\begin{equation}
Q_L = E_L(\mathbb{1}), \quad Q_R = E_R^t(\rho)
\end{equation}
where \(E_R^t(B) = \sum_r T_r^R B(T_r^R)^*\). We assume that \(Q_L\) and \(Q_R\) are non-singular.

For \(\Lambda \in \{G_L, C_n, G_R, G_L - C_n, C_n - G_R\}\), considered as subsets of \(G\), let \(\mathcal{H}_\Lambda\) and \(\mathcal{K}_\Lambda\) denote the corresponding physical and auxiliary Hilbert spaces, respectively, and define the corresponding maps \(\Gamma_\Lambda : \mathcal{K}_\Lambda \rightarrow \mathcal{H}_\Lambda\) in the obvious way. These maps are of the same form as \(\Gamma_G\) in (3.4); if one or both parts described by \(G_L\) or \(G_R\) are absent, the absent degrees of freedom associated with \(G\) correspond to taking \(\mathcal{H}_{G\#} = \mathbb{C}\), \(\mathcal{H}_{G\#} = 0\), and \(T_{G\#} \equiv 1\).

We assume that the maps \(\Gamma_\Lambda\) are injective, meaning
\begin{equation}
dim \text{ran } \Gamma_\Lambda = \dim \mathcal{K}_\Lambda, \quad \text{and } \text{ran } \Gamma_\Lambda = \ker \mathcal{H}_\Lambda.
\end{equation}

### 3.2. General estimate of \(\varepsilon_n\)

Let \(G_\Lambda\) denote \(\ker \mathcal{H}_\Lambda\), and \(P_\Lambda\) the orthogonal projection onto \(G_\Lambda\). Our next goal is to estimate \(\varepsilon_n = \|P_{G_L-C_n} P_{C_n-G_R} - P_G\|\). It is easy to see that \(\varepsilon_n\) is explicitly given by the following expression:
\begin{equation}
\varepsilon_n = \sup \left\{ \frac{\langle \phi, \psi \rangle}{\|\phi\| \|\psi\|} \mid \phi \in \mathcal{G}_{G_L-C_n} \otimes \mathcal{H}_{G_R}, \psi \in \mathcal{H}_{G_L} \otimes \mathcal{G}_{C_n-G_R}, \phi, \psi \perp \mathcal{G}, \phi, \psi \neq 0 \right\}.
\end{equation}

We will derive an estimate of the type of inner products that appear in (3.8), but first recall some basic properties of MPS.

Since \(\rho\) is non-singular and positive, it defines an inner product on \(M_D\) by
\begin{equation}
\langle A, B \rangle_\rho = \text{Tr}_\rho A^* B \quad \text{for all } A, B \in M_D,
\end{equation}
and let \(\| \cdot \|_\rho\) denote the corresponding norm. We will also let \(\rho_{\text{min}}\) denote the smallest eigenvalue of \(\rho\), which is positive by assumption. It follows that the norm \(\| \cdot \|_\rho\) is equivalent to the Hilbert-Schmidt norm on \(M_D\), which is given by \(\| \cdot \|_2 = \sqrt{\text{Tr}_\rho A^* A}\). Explicitly:
\begin{equation}
\|A\|_2 \leq \frac{1}{\sqrt{\rho_{\text{min}}}} \|A\|_\rho, \quad A \in M_D.
\end{equation}

The map \(\Gamma_{C_n} : M_D \rightarrow \mathcal{H}_{C_n}\) is explicitly given by
\begin{equation}
\Gamma_{C_n}(B) = \sum_{i_1, \ldots, i_n} \text{Tr}[BV_{i_1} \cdots V_{i_n}] |i_1, \ldots, i_n\rangle, \quad B \in M_D.
\end{equation}

**Lemma 3.1** ([15 Lemma 5.2]). For any \(B, C \in M_D\),
\begin{equation}
|\langle \Gamma_{C_n}(B), \Gamma_{C_n}(C) \rangle - \langle B, C \rangle_\rho| \leq a(n) \text{Tr}_\rho^{-1} \|B\|_\rho \|C\|_\rho.
\end{equation}
Proof. Using (3.11) we can express the inner product as follows:

\[ \langle \Gamma C_n(B), \Gamma C_n(C) \rangle = \sum_{i_1, \ldots, i_n} \text{Tr}[BV_{i_1} \cdots V_{i_n}] \text{Tr}[CV_{i_1} \cdots V_{i_n}] \]

(3.13)

By expanding the traces using any orthonormal basis \{ |1\rangle, \ldots, |D\rangle \} for \( \mathbb{C}^D \), we obtain

\[ \langle \Gamma C_n(B), \Gamma C_n(C) \rangle = \sum_{\alpha, \beta = 1}^D \langle \alpha | B^* | \alpha \rangle \langle \beta | C V_{i_1} \cdots V_{i_n} | \beta \rangle \]

(3.14)

Now observe that

\[ \langle B, C \rangle_\rho = \sum_{\alpha, \beta = 1}^D \langle \alpha | (\mathbb{I} - |1\rangle \langle 1|) (B^* | \alpha \rangle \langle \beta | C) | \beta \rangle \]

(3.15)

Combining these two expressions and using (3.3), we obtain

\[ |\langle \Gamma C_n(B), \Gamma C_n(C) \rangle - \langle B, C \rangle_\rho| \leq a(n) \left( \sum_{\alpha = 1}^D \| B^* | \alpha \rangle \| \right) \left( \sum_{\beta = 1}^D \| C^* | \beta \rangle \| \right) \]

Now, pick for the orthonormal basis one that diagonalizes \( \rho \), such that \( \rho | \alpha \rangle = \rho_\alpha | \alpha \rangle \). Then

\[ \left( \sum_{\alpha = 1}^D \| B^* | \alpha \rangle \| \right)^2 = \left( \sum_{\alpha = 1}^D \| B^* | \alpha \rangle \| \rho_\alpha^{1/2} \rho_\alpha^{-1/2} \right)^2 \leq \sum_{\alpha = 1}^D \rho_\alpha \langle \alpha | BB^* | \alpha \rangle \sum_{\alpha = 1}^D \rho_\alpha^{-1} = \| B \|_\rho^2 \text{Tr} \rho^{-1} \]

Together with the analogous estimate for the second factor, this proves the lemma. \( \square \)

Note that one has the bound

\[ \text{Tr} \rho^{-1} \leq \frac{D}{\rho_{\text{min}}} \]

which is often saturated in models with symmetry. It will be convenient to define

(3.16) \[ b(n) = a(n) \text{Tr} \rho^{-1} \]

The following is an immediate corollary of Lemma 3.1 and shows that \( \Gamma C_n \) is injective for sufficiently large \( n \).

**Corollary 3.2.** For any \( B \in M_D \), the bound

(3.17) \[ \| B \|_\rho \sqrt{1 - b(n)} \leq \| \Gamma_n(B) \| \leq \| B \|_\rho \sqrt{1 + b(n)} \]

holds for \( n \) sufficiently large so that \( b(n) \leq 1 \).
Proof. The bound

\[ \| \Gamma_{C_n}(B) \|^2 - \| B \|^2 \leq b(n) \| B \|^2 \]

follows immediately from (3.12). If \( B = 0 \), there is nothing to prove. Otherwise, this bound can be re-written as

\[ - b(n) \leq \| \Gamma_{C_n}(B) \|^2 - 1 \leq b(n) \]

from which the above claim readily follows. \( \Box \)

Inner products of vectors of the form \( \Gamma_{\Lambda}(B) \), \( B \in K_{\Lambda} \), can be estimated with a straightforward generalization of Lemma 3.1. To formulate the result, for each \( \Lambda \in \{ G, G_L - C_n, C_n - G_R \} \), we define an inner product on \( K_{\Lambda} \), denoted by \( \langle \cdot, \cdot \rangle_{\Lambda} \), via

\[
\langle B, C \rangle_G = \text{Tr}(Q_R B^* Q_L C) \tag{3.20}
\]

\[
\langle B, C \rangle_{G_L - C_n} = \text{Tr}(\rho B^* Q_L C) \tag{3.21}
\]

\[
\langle B, C \rangle_{C_n - G_R} = \text{Tr}(Q_R B^* C) \tag{3.22}
\]

That these are inner products follows from the positive-definiteness of \( Q_L \) and \( Q_R \). With respect to these inner products, we obtain the following analog of Lemma 3.1.

**Lemma 3.3.** Let \( \Lambda \in \{ G, G_L - C_n, C_n - G_R \} \). Then for any \( B, C \in K_{\Lambda} \),

\[
| \langle \Gamma_{\Lambda}(B), \Gamma_{\Lambda}(C) \rangle - \langle B, C \rangle_{\Lambda} | \leq a(n) D^2 C_{\Lambda} \| B \| \| C \| ,
\]

where

\[
C_G = \| E_L \| \| E_R \| , \quad C_{G_L - C_n} = \| E_L \| , \quad \text{and} \quad C_{C_n - G_R} = \| E_R \|. \tag{3.24}
\]

**Proof.** We prove the bound in the case of \( \Lambda = G \). All other cases follow from similar arguments. Let \( B, C \in K_{G} \), and \( \{ |1\rangle, \ldots, |D\rangle \} \) be an orthonormal basis of \( \mathbb{C}^D \). Then, calculating similar to (3.13) and (3.14), we find

\[
\langle \Gamma_G(B), \Gamma_G(C) \rangle = \sum_{\ell, r} \sum_{i_1, \ldots, i_n} \text{Tr} [V_{i_1}^* \cdots V_{i_n}^* (T_{\ell}^R)^* B^* (T_{\ell}^L)^*] \text{Tr}[T_{\ell}^L C T_{r}^R V_{i_n} \cdots V_{i_1}]
\]

\[
= \sum_{\alpha, \beta = 1}^{D} \langle \alpha | \mathbb{E}^n \circ \mathbb{E}_R [B^* \mathbb{E}_L(|\alpha\rangle \langle \beta|) C] | \beta \rangle ,
\]

where we have also used cyclicity of the trace in the first equality. Now consider \( \langle B, C \rangle_G \). It can easily be shown, e.g. by simplifying the RHS, that

\[
\langle B, C \rangle_G = \sum_{\alpha, \beta = 1}^{D} \langle \alpha | \mathbb{1} \rangle \langle \rho | \circ \mathbb{E}_R [B^* \mathbb{E}_L(|\alpha\rangle \langle \beta|) C] | \beta \rangle .
\]
Let \( q_n \) be the minimal eigenvalue of \( Q_L \) (resp. \( Q_R \)). Then,

\[
\|B\| \leq \frac{1}{\sqrt{q_L q_R}} \|B\|_G, \quad \|B\| \leq \frac{1}{\sqrt{\rho_{\text{min}} q_L}} \|B\|_{G_L - C_n}, \quad \|B\| \leq \frac{1}{\sqrt{q_R}} \|B\|_{C_n - G_R}.
\]

We can thus obtain a corollary to Lemma 3.3 similar to Corollary 3.2.

**Corollary 3.4.** Let \( \Lambda \in \{G, G_L - C_n, C_n - G_R\} \). Then for any \( B \in \mathcal{K}_\Lambda \),

\[
\|B\|_\Lambda \sqrt{1 - b_\Lambda(n)} \leq \|\Gamma_\Lambda(B)\| \leq \|B\|_\Lambda \sqrt{1 + b_\Lambda(n)}
\]

holds for \( n \) sufficiently large so that \( b_\Lambda(n) \leq 1 \), where

\[
b_G(n) = \frac{a(n)D^2}{q_L q_R} \|E_L\| \|E_R\|, \quad b_{G_L - C_n}(n) = \frac{a(n)D^2}{\rho_{\text{min}} q_L} \|E_L\|, \quad b_{C_n - G_R}(n) = \frac{a(n)D^2}{q_R} \|E_R\|.
\]

In order to simplify notation, we will write \( b_L(n) \) for \( b_{G_L - C_n}(n) \) and \( b_R(n) \) for \( b_{C_n - G_R}(n) \).

Ultimately, we will want a bound for the inner product in (3.8) in terms of the norms of the vectors \( \phi \) and \( \psi \) defined below. Lemma 3.3 can also be used to show that this is once again straightforward at the cost of another prefactor in the bound.

Since \( \Gamma_{G_L - C_n} \) and \( \Gamma_{C_n - G_R} \) are assumed to be injective, there exist \( D_R \) \( D_L \times D \) matrices \( B_\phi(r) \), and \( D_L \) \( D \times D_R \) matrices \( B_\psi(l) \), uniquely determined by \( \phi \) and \( \psi \), such that

\[
\phi = \sum_{l_1, \ldots, l_n} \text{Tr}[B_\phi(r)V_{i_1} \cdots V_{i_n}T^L_l] |l\rangle_L \otimes |i_1, \ldots, i_n\rangle \otimes |r\rangle_R
\]

\[
\psi = \sum_{l_1, \ldots, l_n} \text{Tr}[B_\psi(l)T^R_lV_{i_1} \cdots V_{i_n}] |l\rangle_L \otimes |i_1, \ldots, i_n\rangle \otimes |r\rangle_R.
\]
These expressions are simply expansions of
\begin{align}
\phi &= \sum_r \Gamma_{G_L-C_n}(B_{\phi}(r)) \otimes |r\rangle_R \\
\psi &= \sum_l |l\rangle_L \otimes \Gamma_{C_n-G_R}(B_{\psi}(l)).
\end{align}

It will be convenient to define $C_{\phi}, C_{\psi} \in K_G$ as follows:
\begin{align}
C_{\phi} &= \sum_r B_{\phi}(r)\rho(T^R_r)^* \\
D_{\psi} &= \sum_l (T^L_l)^* B_{\psi}(l).
\end{align}

Next, we consider inner products of the form $\langle \phi, \psi \rangle$, with $\phi \in G_{G_L-C_n} \otimes H_{G_R}$ and $\psi \in H_{G_L} \otimes G_{C_n-G_R}$.

**Lemma 3.5.** Suppose that $n$ is large enough so that $b(n) < 1$. Then, for all $\phi \in G_{G_L-C_n} \otimes H_{G_R}$ and $\psi \in H_{G_L} \otimes G_{C_n-G_R}$, we have
\begin{align}
|\langle \phi, \psi \rangle - \langle C_{\phi}, D_{\psi} \rangle_{K_G}| &\leq \frac{b(n)}{\sqrt{1-b_{LR}(n)}} \|\phi\|\|\psi\|,
\end{align}
where
\begin{align}
b_{LR}(n) &= b_L(n) + b_R(n) - b_L(n)b_R(n),
\end{align}
and $b_L(n)$ and $b_R(n)$ are defined in (3.30).

**Proof.** Using the expansions (3.31) and (3.32) we find
\begin{align}
\langle \phi, \psi \rangle &= \sum_{l,i_1,...,i_n,r} \text{Tr}[B_{\phi}(r)V_{i_n} \cdots V_{i_1} T^L_l] \text{Tr}[B_{\psi}(l)T^R_r V_{i_n} \cdots V_{i_1}]
\end{align}
\begin{align}
&= \sum_{l,r} \langle \Gamma_{C_n}(T^L_l B_{\phi}(r)), \Gamma_{C_n}(B_{\psi}(l)T^R_r) \rangle
\end{align}

Similarly, we observe that $\langle C_{\phi}, D_{\psi} \rangle_{K_G}$ can be expressed as a sum of inner products:
\begin{align}
\langle C_{\phi}, D_{\psi} \rangle_{K_G} &= \text{Tr} \left( \sum_r T^R_r \rho B\phi(r)^* \right) \left( \sum_l (T^L_l)^* B\psi(l) \right)
\end{align}
\begin{align}
&= \sum_{l,r} \text{Tr} \rho B\phi(r)^* (T^L_l)^* B\psi(l) T^R_r
\end{align}
\begin{align}
&= \sum_{l,r} \langle T^L_l B\phi(r), B\psi(l)T^R_r \rangle \rho.
Now we apply Lemma 3.1 term by term to obtain, using Cauchy-Schwarz:

\[
|⟨\varphi, ψ⟩ - ⟨C_φ, D_ψ⟩_{K_G}| \leq \sum_{l,r} |⟨Γ_{C_n}(T_l^L B_φ(r)), Γ_{C_n}(B_ψ(l)T_r^R)⟩ - ⟨T_l^L B_φ(r), B_ψ(l)T_r^R⟩_ρ|
\]

\[
\leq b(n) \sum_{l,r} ∥T_l^L B_φ(r)∥_ρ \cdot ∥B_ψ(l)T_r^R∥_ρ
\]

(3.40)

\[
\leq b(n) \sqrt{\sum_{l,r} ∥T_l^L B_φ(r)∥_ρ^2} \cdot \sqrt{\sum_{l,r} ∥B_ψ(l)T_r^R∥_ρ^2}.
\]

The quantity under the first square root can be bounded in terms of ∥φ∥ as follows:

\[
\sum_{l,r} ∥T_l^L B_φ(r)∥_ρ^2 = \sum_{l,r} \text{Tr}_ρ B_φ(r)^* (T_l^L)^* T_l^L B_φ(r)
\]

\[
= \sum_r \text{Tr}_ρ B_φ(r)^* Q_L B_φ(r) = \sum_r ∥B_φ(r)∥_{G_L−C_n}^2
\]

\[
\leq \frac{1}{1−b_L(n)} \sum_r ∥Γ_{G_L−C_n}(B_φ(r))∥^2
\]

\[
= \frac{1}{1−b_L(n)} ∥φ∥^2,
\]

where we have used the definition of Q_L, Corollary 3.4 and (3.33). The quantity under the second square root is similarly estimated in terms of ∥ψ∥:

(3.41)

\[
\sum_{l,r} ∥B_ψ(l)T_r^R∥_ρ^2 \leq \frac{1}{1−b_R(n)} ∥ψ∥^2.
\]

Inserting these into (3.40) yields

(3.42)

\[
|⟨\varphi, ψ⟩ - ⟨C_φ, D_ψ⟩_{K_G}| \leq \frac{b(n)}{\sqrt{1−b_L(n)}(1−b_R(n))} ∥φ∥∥ψ∥.
\]

□

Now, we are ready to estimate the quantity of interest in (3.8), which is an inner product of the form considered in Lemma 3.5 with the additional information that φ and ψ are both orthogonal to G_G.

**Proposition 3.6.** Under the assumptions stated in Section 3.1 and with the notations introduced there, we have the following estimate for the quantity ε_n defined in (3.8):

(3.43)

\[
ε_n \leq \frac{b(n)}{\sqrt{1−b_{LR}(n)}} + \left(\frac{b(n)}{\sqrt{1−b_{LR}(n)}}\right)^2 (1 + b_G(n)),
\]

with

(3.44)

\[
b(n) = a(n)\text{Tr}_ρ^{-1}, \quad a(n) = ∥E^n − |1⟩⟨1|_ρ∥,
\]

and b_{LR}(n) and b_G(n) are defined in (3.30) and (3.38).
Proof. Any $\xi \in \mathcal{G}_G$ belongs to both $\mathcal{G}_{G_L-C_n} \otimes \mathcal{H}_{G_R}$ and $\mathcal{H}_{G_L} \otimes \mathcal{G}_{C_n-G_R}$. Therefore, there are unique matrices $B_\xi(r)$ and $B_\xi(l)$ and corresponding expressions (3.31) and (3.32) for $\xi$. Since $\xi \in \mathcal{G}_G$, there also exists $X \in \mathcal{K}_G$ such that $\xi = \Gamma_G(X)$. By injectivity it follows that

$$B_\xi^L(l) = T_l^L, \quad B_\xi^R(r) = X T_r^R.$$  

Inserting the first relation above into the expression for $D_\psi$ and the second into $C_\phi$ we find the following special form of these matrices for a ground state $\xi$:

$$C_\xi = \sum_r B_\phi(r) \rho(T_r^R)^* = \sum_r X T_r^R \rho(T_r^R)^* = XQ_R$$

$$D_\xi = \sum_l (T_l^L)^* B_\psi(l) = \sum_l (T_l^L)^* T_l^L X = Q_L X.$$  

We use this to extract information from the orthogonality of $\phi$ and $\psi$ to $\mathcal{G}_G$. Using $\langle \phi, \xi \rangle = \langle \xi, \psi \rangle = 0$, from Lemma [3.5] we have that for all $X \in \mathbb{C}^{D_L \times D_L}$:

$$|\langle C_\phi, Q_L X \rangle_{\mathcal{K}_G}| \leq \frac{b(n)}{\sqrt{1 - b_{LR}(n)}} \|\phi\| \|\xi\|$$  

$$|\langle XQ_R, D_\psi \rangle_{\mathcal{K}_G}| \leq \frac{b(n)}{\sqrt{1 - b_{LR}(n)}} \|\xi\| \|\psi\|.$$  

Applying Corollary 3.4 gives

$$\|\xi\|^2 = \|\Gamma_G(X)\|^2 \leq (1 + b_G(n)) \|X\|^2_G.$$  

Using this with (3.48) and (3.49) yields

$$|\langle C_\phi, Q_L X \rangle_{\mathcal{K}_G}| \leq \delta(n) \|\phi\| \|X\|_G$$

$$|\langle XQ_R, D_\psi \rangle_{\mathcal{K}_G}| \leq \delta(n) \|\psi\| \|X\|_G,$$

where

$$\delta(n) = \frac{b(n)}{\sqrt{1 - b_{LR}(n)}} \sqrt{1 + b_G(n)}.$$  

The LHS of these inequalities can be expressed in terms of the inner product $\langle \cdot, \cdot \rangle_G$ as follows:

$$\langle C_\phi, Q_L X \rangle_{\mathcal{K}_G} = \text{Tr} C_\phi^* Q_L X = \text{Tr} Q_R C_\phi^* Q_L X = \langle C_\phi Q_R^{-1}, X \rangle_G$$

$$\langle XQ_R, D_\psi \rangle_{\mathcal{K}_G} = \text{Tr} Q_R X^* D_\psi = \text{Tr} Q_R X^* Q_L Q_L^{-1} D_\psi = \langle X, Q_L^{-1} D_\psi \rangle_G.$$  

The estimates (3.50) now become: for all $X$

$$|\langle C_\phi Q_R^{-1}, X \rangle_G| \leq \delta(n) \|\phi\| \|X\|_G$$

$$|\langle X, Q_L^{-1} D_\psi \rangle_G| \leq \delta(n) \|\psi\| \|X\|_G,$$

which imply

$$\|C_\phi Q_R^{-1}\|_G \leq \delta(n) \|\phi\|$$

$$\|Q_L^{-1} D_\psi\|_G \leq \delta(n) \|\psi\|.$$  

Noting the identity

$$\langle C_\phi, D_\psi \rangle_{\mathcal{K}_G} = \text{Tr} Q_R (Q_R^{-1} C_\phi^*) Q_L (Q_L^{-1} D_\psi) = \langle C_\phi Q_R^{-1}, Q_L^{-1} D_\psi \rangle_G,$$

we have

$$|\langle C_\phi, D_\psi \rangle_{\mathcal{K}_G}| \leq \|C_\phi Q_R^{-1}\|_G \|Q_L^{-1} D_\psi\|_G \leq \delta(n)^2 \|\phi\| \|\psi\|.$$
Moreover, it follows from (3.37) that
\begin{equation}
|\langle \phi, \psi \rangle| \leq |\langle C\phi, D\psi \rangle_{K_G}| + \frac{b(n)}{\sqrt{1 - b_{LR}(n)}} \|\phi\| \|\psi\|.
\end{equation}
Combining the last two inequalities we obtain the final estimate
\begin{equation}
|\langle \phi, \psi \rangle| \leq \left[ \frac{b(n)}{\sqrt{1 - b_{LR}(n)}} + \left( \frac{b(n)}{\sqrt{1 - b_{LR}(n)}} \right)^2 (1 + b_G(n)) \right] \|\phi\| \|\psi\|.
\end{equation}

In the next section we verify the assumptions stated in this section for the AKLT model on the decorated honeycomb lattice with \( n \geq 2 \) and apply Proposition 3.6 to show that for this model we have \( \varepsilon_n < 1/3 \), for all \( n \geq 3 \).

4. GAP OF THE DECORATED AKLT MODEL

In this section we prove Proposition 2.1 and Theorem 2.2 by applying the results of Section 3 to the decorated AKLT model discussed in Section 2. In this case, the graph \( G \) is given by \( Y_v \cup Y_w \) for two adjacent sites \( v \) and \( w \) in \( \Gamma \). We decompose \( G \) as \( G = G_L - C_n - G_R \), where \( C_n = Y_v \cap Y_w \), \( G_L = Y_v \setminus C_n \) and \( G_R = Y_w \setminus C_n \). The VBS (Valence Bond Solid) or PEPS (Product of Entangled Pairs) ground states on \( G \) are depicted in Figure 3. The corresponding Hilbert spaces are give by
\[ \mathcal{H}_G = \mathcal{H}_{G_L} = (\mathbb{C}^3 \otimes \mathbb{C}^3)^{\otimes n} \otimes \mathbb{C}^4, \quad \text{and} \quad \mathcal{H}_{C_n} = (\mathbb{C}^3)^{\otimes n}. \]
For \( s \in \{1, 3/2\} \), we use \( B_s = \{|s\}, |s-1\rangle, \ldots, |1\rangle \) to denote an orthonormal basis of \( \mathbb{C}^{2s+1} \) consisting of eigenvectors of the third component of spin associated to the spin-\( s \) irreducible representation of \( SU(2) \). We begin by discussing the MPS \( \Gamma_{C_n} \) and its associated transfer operator \( \mathbb{E} \). We then define the operator \( \mathbb{E}_{GL} \) associated with \( G_L \) and prove that \( \Gamma_{G_L-C_n} \) is injective for \( n \geq 2 \), after which we prove the main results.
On $C_n$ we have the one-dimensional AKLT spin chain, which has the bond dimension $D = 2$. For this model, every physical spin-$1$ vertex is identified with the symmetric subspace of the virtual space $C^2 \otimes C^2$. We will denote by $S^X, S^Y, S^Z$ the usual spin-$1/2$ operators, and by $S^\pm$ the corresponding lowering and raising operators. To differentiate between the physical and virtual spins, we will use $|\uparrow\rangle, |\downarrow\rangle \in C^2$ to denote the standard orthonormal eigenbasis of $S^Z$ rather than $|\pm \rangle$. The intertwiner $P^{(1)}_{\text{sym}} : C^2 \otimes C^2 \rightarrow C^3$ that maps between the virtual and physical space of a site $v$ is given by:

\[
P^{(1)}_{\text{sym}} = \frac{1}{\sqrt{2}} |\uparrow\rangle \langle \uparrow\uparrow| + |0\rangle \langle \psi^+| + |\downarrow\rangle \langle \downarrow\downarrow|,
\]

where $|\psi^+\rangle = \frac{1}{\sqrt{2}} (|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle)$.

Recall that the symmetric subspace of $C^2 \otimes C^2$ can be encoded into the MPS matrices

\[
P^{(1)}_1 = |\uparrow\rangle \langle \uparrow|, \quad P^{(1)}_0 = \sqrt{2} S^X, \quad P^{(1)}_{-1} = |\downarrow\rangle \langle \downarrow|.
\]

The ground states of the one-dimensional AKLT model can then be described as a valence-bond solid state obtained from projecting each (virtual) edge of the graph into the singlet states $|\psi^-\rangle = \frac{1}{\sqrt{2}} (|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle)$; this is represented by the MPS matrix

\[
K = \frac{1}{\sqrt{2}} (|\uparrow\rangle \langle \downarrow| - |\downarrow\rangle \langle \uparrow|) = \sqrt{i} S^Y.
\]

With these matrices, and with a convenient choice of normalization, the ground state space of the one-dimensional AKLT matrix is given by

\[
\Gamma_{C_n}(B) = \sum_{i_1, \ldots, i_n \in \{\pm 1, 0\}} \text{Tr}[BV_{i_n} \cdots V_{i_1}] |i_1 \ldots i_n\rangle
\]

where $V_i = \frac{2}{\sqrt{3}} K P^{(1)}_i$. Explicitly,

\[
V_1 = -\sqrt{\frac{2}{3}} S^+, \quad V_0 = \frac{2}{\sqrt{3}} S^Z, \quad V_{-1} = \sqrt{\frac{2}{3}} S^-.
\]

Given the form of $\Gamma_{C_n}$, the choice of multiplying on the left by $K$ in the definition of $V_i$ corresponds to projecting the edge to the right of the associated site into the singlet state. This convention will also be used to define the tensors $T^L_\ell$ and $T^R_r$. For more details on this and other MPS constructions, see [41, 39, 37].

Noting that $S^+ BS^- + S^+ BS^- = 2(S^X BS^X + S^Y BS^Y)$, the transfer operator $E : M_2 \rightarrow M_2$ associated with $\Gamma_{C_n}$ takes the form

\[
E(B) = \sum_{i \in \{\pm 1, 0\}} V_i^* B V_i = \frac{4}{3} (S^X BS^X + S^Y BS^Y + S^Z BS^Z),
\]

which can be easily diagonalized as

\[
E = |1\rangle\langle \rho| - \frac{2}{3} \sum_{U \in \{X,Y,Z\}} |S^U\rangle\langle S^U|,
\]

where $\rho = 1/2$ is the maximally mixed state. This allows to easily compute

\[
E^n = |1\rangle\langle \rho| + 2 \left( -1 \right)^n \frac{n}{3^n} \sum_{U \in \{X,Y,Z\}} |S^{U^n}\rangle\langle S^{U^n}|,
\]
from which (3.3) takes the explicit form
\[ a(n) = \|E^n - |\rangle \langle |\| = 3^{-n}, \]
and \( b(n) = \text{Tr}(\rho^{-1})a(n) = 4 \cdot 3^{-n} \). By Corollary 3.2 this implies that \( \Gamma_{C_n} \) is injective when \( n \geq 2 \). It can easily be shown that it is not injective for \( n = 1 \).

We now consider \( G_L \) and \( G_R \). For the decorated AKLT model, \( D_L = D_R = 4 \) and so \( K_G = M_4 \). We first construct the operator \( E_L \) associated with \( G_L \), and use this to prove \( \Gamma_{G_L-C_n} \) is injective of \( n \geq 2 \). The analogous operator \( E_R \) for \( G_R \) and the injectivity of of \( \Gamma_{C_n-G_R} \) follow from similar calculations.

We first note that \( G_L \) can be written as \([u^1_1, u^1_n] \times [u^2_1, u^2_n] \times \{v\} \), where the sites \( u^i_k \) correspond to the \( 2n \) spin-1’s, and \( v \) is the spin-3/2. By grouping the sites \( u^1_i \) and \( u^2_i \) into a single site \((u^1_i, u^2_i)\), we can recognize the ground states of \( H_{G_L} \), as a PEPS. We choose the product basis for \( H_{G_L} \) given by
\[ |i_1, j_1 \rangle \otimes \cdots \otimes |i_n, j_n \rangle \otimes |k \rangle \quad i_1, \ldots, i_n, j_1, \ldots, j_n \in \{ \pm 1, 0 \}, \; k \in \left\{ \pm \frac{3}{2}, \pm \frac{1}{2} \right\}. \]

For each element \( |l \rangle_L = |i_1, j_1 \rangle \otimes \cdots \otimes |i_n, j_n \rangle \otimes |k \rangle \) of the basis, the \( 2 \times 4 \) matrix \( T^L_i \) is given by
\[ T^L_i = W^L_k V^k_i \otimes V^j_n \cdots V^j_1, \]
where the \( V^k_i \) are as defined in (3.1), and the \( W^L_k \in \mathcal{L}(\mathbb{C}^4, \mathbb{C}^2) \) are given by the PEPS representation of the AKLT on the hexagonal lattice, which we now define. Analogous to the spin-1 case, the virtual space of a spin-3/2 particle is the symmetric subspace of three spin-1/2 particles, and so the intertwiner \( P^{(3/2)}_{\text{sym}} : \mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2 \to \mathbb{C}^4 \) between the virtual and physical space is given by
\[ P^{(3/2)}_{\text{sym}} = |3/2\rangle \langle \uparrow\uparrow\uparrow| + |1/2\rangle \langle \phi^+| + |-1/2\rangle \langle \phi^-| + |-3/2\rangle \langle \downarrow\downarrow\downarrow|, \]
where
\[ |\phi^+\rangle = \frac{1}{\sqrt{3}}(|\uparrow\uparrow\downarrow\rangle + |\uparrow\downarrow\uparrow\rangle + |\downarrow\uparrow\uparrow\rangle) = \frac{1}{\sqrt{3}}|\downarrow\rangle |\uparrow\rangle + \sqrt{\frac{2}{3}}|\uparrow\rangle |\psi^+\rangle, \]
\[ |\phi^-\rangle = \frac{1}{\sqrt{3}}(|\uparrow\downarrow\downarrow\rangle + |\downarrow\uparrow\downarrow\rangle + |\downarrow\downarrow\uparrow\rangle) = \frac{1}{\sqrt{3}}|\uparrow\rangle |\downarrow\rangle + \sqrt{\frac{2}{3}}|\downarrow\rangle |\psi^+\rangle. \]

By grouping two virtual edges to the left of \( v \), see Figure 3, the virtual space can be represented by the MPS matrices \( P^{(3/2)}_k \in M_{2 \times 4} \) defined by
\[ P^{(3/2)}_{3/2} = |\uparrow\rangle |\uparrow\rangle, \quad P^{(3/2)}_{1/2} = \frac{1}{\sqrt{3}}|\downarrow\rangle |\uparrow\rangle + \sqrt{\frac{2}{3}}|\uparrow\rangle |\psi^+\rangle \]
\[ P^{(3/2)}_{-3/2} = |\downarrow\rangle |\downarrow\rangle, \quad P^{(3/2)}_{-1/2} = \frac{1}{\sqrt{3}}|\uparrow\rangle |\downarrow\rangle + \sqrt{\frac{2}{3}}|\downarrow\rangle |\psi^+\rangle. \]

Once again projecting edges on the right of \( v \) into a singlet state (and choosing a convenient normalization) we define \( W^L_k = \sqrt{2}K P^{(3/2)}_k \). Explicitly,
\[ W^{3/2}_3 = -|\downarrow\rangle |\uparrow\rangle, \quad W^{3/2}_1 = \frac{1}{\sqrt{3}}|\uparrow\rangle |\uparrow\rangle - \sqrt{\frac{2}{3}}|\downarrow\rangle |\psi^+\rangle, \]
\[ W^{-3/2}_3 = |\uparrow\rangle |\downarrow\rangle, \quad W^{-3/2}_1 = -\frac{1}{\sqrt{3}}|\downarrow\rangle |\downarrow\rangle + \sqrt{\frac{2}{3}}|\uparrow\rangle |\psi^+\rangle, \]
which satisfies $\sum_{i=1}^{4} W_i^L(W_i^L)^* = 2 \mathbb{1}_{c^2}$. For $B \in M_2$, define $E^\tau(B) = \sum_i (W_i^L)^* B W_i^L$. While this is a completely positive map from $M_2$ to $M_4$, unlike the MPS case it is not unital, since

$$E^\tau(\mathbb{1}) = \sum_{i=1}^{4} (W_i^L)^* W_i^L = \frac{4}{3} (|\uparrow\uparrow\rangle\langle\uparrow\uparrow| + |\downarrow\downarrow\rangle\langle\downarrow\downarrow| + |\psi^+\rangle\langle\psi^+|) = \mathbb{1} + \frac{4}{3} S \cdot S,$$

where as usual $S = (S^X, S^Y, S^Z)$ and $S \cdot S = S^X \otimes S^X + S^Y \otimes S^Y + S^Z \otimes S^Z$. By direct calculation, we see that

$$(4.8) \quad (E^\tau)^*(B) = c(B)\rho + \sum_{U \in \{X,Y,Z\}} c_U(B) S^U,$$

where

$$c(B) = \frac{4}{3} \frac{2\sqrt{2}}{3} \text{Re}[\langle \psi^+ | B | \uparrow\uparrow \rangle] + \langle \downarrow\downarrow | B | \psi^+ \rangle \langle \psi^+ | B | \psi^+ \rangle$$

$$c_X(B) = -\frac{2\sqrt{2}}{3} \text{Re}[\langle \psi^+ | B | \uparrow\uparrow \rangle] + \langle \downarrow\downarrow | B | \psi^+ \rangle \langle \psi^+ | B | \psi^+ \rangle$$

$$c_Y(B) = -\frac{2\sqrt{2}}{3} \text{Im}[\langle \psi^+ | B | \uparrow\uparrow \rangle] + \langle \downarrow\downarrow | B | \psi^+ \rangle \langle \psi^+ | B | \psi^+ \rangle$$

$$c_Z(B) = -\frac{2}{3} (\langle \downarrow\downarrow | B | \downarrow\downarrow \rangle - \langle \uparrow\uparrow | B | \uparrow\uparrow \rangle).$$

It can easily be checked that $(E^\tau)^t \circ \tau = (E^\tau)^t$ where $\tau : M_4 \to M_4$ is the transposition operator

$$\tau(A \otimes B) = B \otimes A$$

Combining this with $(4.8)$ allows us to verify that

$$(E^\tau)^t(\rho \otimes \rho) = \rho, \quad (E^\tau)^t(S^U \otimes S^{U'}) = \delta_{U,U'} \frac{1}{3} \rho, \quad (E^\tau)^t(\rho \otimes S^U) = (E^\tau)^t(S^U \otimes \rho) = -\frac{1}{3} S^U,$$

or equivalently

$$(4.9) \quad E^\tau = |\mathbb{1} \otimes \mathbb{1}\rangle \langle \mathbb{1} | + \frac{4}{3} \frac{2\sqrt{2}}{3} \sum_{U \in \{X,Y,Z\}} (|S^U \otimes \mathbb{1}\rangle + |\mathbb{1} \otimes S^U\rangle) \langle S^U |.$$

To simplify notation we define

$$|\Omega^U\rangle = |S^U \otimes \mathbb{1}\rangle + |\mathbb{1} \otimes S^U\rangle \quad \forall U \in \{X,Y,Z\},$$

and notice that

$$\|S \cdot S\|_2 = \frac{\sqrt{3}}{2}, \quad \|\Omega^U\|_2 = \sqrt{2}, \quad \text{and} \quad \langle S \cdot S, \Omega^U \rangle_2 = 0$$

for all $U$. The transfer matrix for $G_L$, defined in $(3.5)$, is then given by $E_L = (E^n \otimes E^n) \circ E^\tau$, which can be simplified to

$$(4.10) \quad E_L = |\mathbb{1} \otimes \mathbb{1}\rangle \langle \mathbb{1} | + \frac{4}{3n+4} \sum_{U} |\Omega^U \rangle \langle S^U | \frac{1}{3n} \sum_{U} |S^U \rangle \langle S^U | E^\tau$$

$$+ \frac{4}{3n+4} \sum_{U} |\Omega^U \rangle \langle S^U | + \frac{4}{3n+4} |S \cdot S\rangle \langle \mathbb{1} |.$$
Using this decomposition to compute $Q_L$ gives
\begin{equation}
Q_L = \mathbb{1} + \frac{4}{3^{2n+1}} S \cdot S, \quad \implies \text{spec}(Q_L) = \left\{ 1 - \frac{1}{3^{2n}}, 1 + \frac{1}{3^{2n+1}} \right\}.
\end{equation}

Therefore, $q_L = 1 - \frac{1}{3^{2n}}$, and moreover, since $E_L$ is a completely positive map,
\[ \|E_L\| = \|Q_L\| = 1 + \frac{1}{3^{2n+1}}. \]

Since $Q_L$ is invertible, the theory of Section 3 applies and we can use the above relations to prove the following result.

**Lemma 4.1.** $\Gamma_{G_L-C_n}$ is injective for $n \geq 2$.

**Proof.** Let $B \in M_D$ and consider $\Gamma_{G_L-C_n}(B)$. Applying Corollary 3.4 gives
\[ \|\Gamma_{G_L-C_n}(B)\|^2 \geq (1 - b_L(n)) \|B\|_{G_L-C_n}^2 \]
with $b_L(n) = \frac{4a(n)\|E_L\|}{\rho_{\min}^n Q_L}$. By inserting the values of $a(n)$, $\|E_L\|$, $\rho_{\min}$, and $q_L$ into this expression, one finds that
\[ 1 - b_L(n) = 1 - \frac{8(1 + 3^{-2n-1})}{3^n(1 - 3^{-2n})}. \]

This quantity is strictly positive for any $n \geq 2$ from which it follows that $\Gamma_{G_L-C_n}$ is injective. \hfill \Box

We now consider $G_R$. The operator $E_R$ is obtained using a similar construction as $E_L$. As with $G_L$, we can once again can group the spin-1 particles into pairs and to construct an orthonormal basis
\[ |r\rangle = |i_1, j_1\rangle \otimes \cdots \otimes |i_n, j_n\rangle \otimes |k\rangle \quad i_1, \ldots, i_n, j_1, \ldots, j_n \in \{\pm 1, 0\}, \quad k \in \left\{ \pm \frac{3}{2}, \pm \frac{1}{2} \right\}, \]
for which the corresponding tensor is given by
\begin{equation}
T^R_r = V_{i_n} \otimes V_{j_n} \cdots V_{i_1} \otimes V_{j_1} W^R_k,
\end{equation}
where $V_1$, $V_0$ and $V_{-1}$ are as before, and $W^R = 2K \otimes K(P^R_k)^*$. Explicitly,
\begin{align}
W^R_{3/2} &= |\downarrow \downarrow\rangle \uparrow|, \quad W^R_{1/2} = \frac{1}{\sqrt{3}}(|\downarrow \uparrow\rangle \downarrow| - \sqrt{\frac{2}{3}}|\psi^+\rangle \uparrow|), \\
W^R_{-3/2} &= |\uparrow \uparrow\rangle \downarrow|, \quad W^R_{-1/2} = \frac{1}{\sqrt{3}}(|\uparrow \downarrow\rangle \uparrow| - \sqrt{\frac{2}{3}}|\psi^+\rangle \downarrow|. \end{align}

Similar to the case of $E^L$, we have $E^R := E^c \circ (E^n \otimes E^n)$ where $E^c : M_4 \to M_2$ is defined by
\begin{equation}
E^c(B) := \sum_i (W^R_i)^* B W^R_i = \sum_i W^L_i B (W^L_i)^* = (E^c)^i(B).
\end{equation}

The final equality above follows from recognizing
\begin{align}
W^R_{3/2} &= (W^L_{-3/2})^*, \quad W^R_{1/2} = -(W^L_{-1/2})^* \\
W^R_{-3/2} &= -(W^L_{3/2})^*, \quad W^R_{-1/2} = (W^L_{1/2})^*.
\end{align}

It follows from the analogous arguments as used in Lemma 4.1 above that $\Gamma_{C_n-G_R}$ is also injective for $n \geq 2$. We can now prove Proposition 2.1 and Theorem 2.2.
Proof of Proposition 2.1 and Theorem 2.2. Since $E = E^t$, from (4.15) it follows that $E_R = [(E^r \otimes E^n) \circ E^r]^t = (E_L)^t$. Therefore, $\|E_R\| = \|E_L\|$ and

$$Q_R := (E_R)^t(\rho) = E_L(\rho) = \frac{1}{2}Q_L.$$  

As a consequence,

$$q_R = \frac{1}{2}q_L = \rho_{\min}q_L.$$

Using (3.43) to estimate (3.8), we find

$$\varepsilon_n \leq \frac{4a(n)}{\sqrt{1 - b_{LR}(n)}} + \left(\frac{4a(n)}{\sqrt{1 - b_{LR}(n)}}\right)^2 \left(1 + b_G(n)\right).$$

From (3.30) and the values above, it is clear that $b_L(n) = b_R(n)$, and so

$$1 - b_{LR}(n) = (1 - b_L(n))(1 - b_R(n)) = \left(1 - \frac{8(1 + 3^{-2n-1})}{3^n(1 - 3^{-2n})}\right)^2,$$

$$1 + b_G(n) = \left(1 + \frac{8(1 + 3^{-2n-1})^2}{3^n(1 - 3^{-2n})}\right).$$

This establishes Proposition 2.1.

Inserting these into (4.19), we find that $\varepsilon_n < \frac{1}{3}$ whenever $n \geq 3$. By (2.9) this implies that the decorated AKLT model has a positive spectral gap above the ground state energy for $n \geq 3$. This completes the proof of Theorem 2.2.

5. Discussion

We proved an explicit positive lower bound for the spectral gap above the ground state of the AKLT model on the decorated honeycomb lattice for $n \geq 3$, where $n$ is the number of vertices inserted on each edge of the honeycomb lattice. It is natural to ask whether the approach of this paper could be used to prove that the AKLT model on the honeycomb lattice itself ($n = 0$) is gapped too, which is expected. It is clear to us, however, that significant changes to the arguments would be necessary to achieve this. For example, a numerical calculation shows that $\varepsilon_1 \sim .478 > 1/3$. Therefore, our method does not work for $n = 1$. For the case $n = 2$, we do not have a good estimate of $\varepsilon_2$, but it is conceivable that our approach could be extended to the case $n = 2$. For the model with $n = 3$, however, we proved a positive lower bound. By using a numerically calculated value for the gap for the small system on $Y$, which appears in (2.4), ($\gamma_Y \sim 0.2966$), and the rigorous estimate showing $\varepsilon_3 < 0.2683$ (Proposition 2.1), we found the following uniform lower bound for the gap: $\gamma > 0.0289$.

About generalizations to frustration-free models on other decorated lattices on the other hand, we can be rather optimistic. For example, we expect that similar arguments will work to study the spectral of AKLT models on decorated hypercubic lattices of any dimension. One could also try to apply our approach to some of the more exotic hybrid valence bond models discussed in [44].
For physical reasons, one wants the spectral gap to be robust under small perturbations of the interactions. It seems very likely that the AKLT models on the decorated honeycomb lattices (and likely also on the honeycomb lattice itself) satisfy the Local Topological Quantum Order condition introduced by Bravyi, Hastings, and Michalakis [12]. If so, the stability theorem of Michalakis and Zwolak [31] would apply to the AKLT models on decorated lattices and provide the desired robustness of the spectral gap.

Acknowledgments

This work arose from discussions during the follow-up workshop on Gapped Ground State Phases of Quantum Many-Body Systems to the 2018 Arizona School of Analysis and Mathematical Physics, organized by Robert Sims and two of the authors (H. A. and A. Y.) and supported by NSF Grant DMS-1800724. A. L. acknowledges support from the Walter Burke Institute for Theoretical Physics in the form of the Sherman Fairchild Fellowship as well as support from the Institute for Quantum Information and Matter (IQIM), an NSF Physics Frontiers Center (NFS Grant PHY-1733907). B. N. acknowledges support by the National Science Foundation under Grant DMS-1813149 and a CRM-Simons Professorship for a stay at the Centre de Recherches Mathématiques (Montréal) during Fall 2018, where part of this work was carried out.
