ABSTRACT

Background: The TORCH phase III trial compared the efficacy of first-line erlotinib followed by chemotherapy at progression (experimental arm) with the reverse sequence (standard arm) in unselected advanced non-small cell lung cancer (NSCLC) patients. Here we report biomarker analyses.

Methods: EGFR and KRAS mutation, expression of EGFR family members and of cMET and PTEN and EGFR and ABCG2 germline polymorphisms were tested on tumor tissue or blood samples to either confirm previously proposed predictive role or describe it in an explorative setting. Progression-free survival (PFS) was the primary end-point, overall survival, response rate and side effects (diarrhoea and skin toxicity) were secondary end-points. Interactions between biomarkers and treatment were studied with multivariable models (either Cox model or logistic regression). Statistical analyses accounted for multiple comparisons.

Results: At least one biomarker was assessed in 324 out of 760 patients in the TORCH study. EGFR mutation was more common in female (P = 0.0001), East Asians...
(P < 0.0001) and never smoker (P < 0.0001) patients; low MET protein expression by IHC (H-score <200) was more frequent in squamous (P < 0.00009) and ABCG2 C/A or A/A polymorphism was more frequent among East-Asian patients (P = 0.0003). A significant interaction was found for EGFR mutation in PFS and response rate analyses while no predictive effect on OS was found for any biomarker. No biomarker tested was prognostic for PFS and OS. No polymorphism was significantly associated with skin toxicity or diarrhea.

Conclusion: In the present study, beyond the known role of EGFR mutation, no other biomarker has predictive or prognostic role.

RESULTS

Details of patients’ flow and samples available for each biomarker are reported in Supplementary Figure S2. 556 patients consented to biomarker studies and at least one biomarker was tested for 324 (42.6%) patients (study population). Baseline characteristics of the biomarker population were comparable to both the population of patients (N = 673) enrolled in centers that provided at least one sample and the whole trial patient population (N = 760) (Supplementary Table S2).

Distribution of biomarkers categories is reported in Table 1. All biomarkers were balanced between treatment arms. Due to low prevalence or absence of positive cases, HER2 and HER3 were excluded from further analyses.

Associations between each biomarker and baseline patients characteristics are described in Supplementary Tables S3 to S13. According to the predefined 0.001 threshold for statistical significance, EGFR mutation was significantly more common in female (p = 0.0001), East Asians (P < 0.0001) and never smoker (P < 0.0001) patients; low MET protein expression by IHC (H-score < 200) was more frequent in case of squamous carcinoma (P = 0.00009) and ABCG2 C/A or A/A polymorphism was more frequent among East-Asian patients (P = 0.0003).

Pairwise association between biomarkers is reported in Supplementary Table S14. No association was significant at the predefined level of 0.001, with the exception of the obvious one between the two scoring systems for MET protein expression by IHC.

The modifying effects of biomarkers on PFS, OS and response to first treatment are provided in Figures 1 to 3. A significant interaction was only found for EGFR mutation in PFS (Figure 1) and response rate analyses (Figure 3) while no predictive effect on OS was found for any biomarker (Figure 2) at the predefined Bonferroni-Holm sequential significance levels.

In an exploratory unplanned analysis of patients with non-mutated EGFR or EGFR mutation unknown status, ABCG2 polymorphism had a significant (P = 0.003) interaction with treatment effect on PFS (HR for erlotinib vs chemotherapy was 0.62, 95%CI 0.28-1.34 among A/C or A/A and 2.07, 95%CI 1.54-2.80 among C/C ABCG2 polymorphisms). Further, adjustment for the Asian ethnicity, which was significantly more common in

INTRODUCTION

The discovery of oncogenic mutations in the tyrosine kinase (TK) domain of the epidermal growth factor receptor (EGFR) gene, and sensitivity of mutant lung cancers to EGFR-TK inhibitors (TKIs), have revolutionized the treatment of advanced NSCLC. Erlotinib, one of the first generation EGFR-TKIs, has become a standard first line drug for patients with EGFR mutant lung cancers.[1] However, only 60-80% of NSCLC patients with EGFR mutant tumour respond to EGFR-TKI therapy,[2-5] while a small proportion of patients with EGFR wild-type tumors may also benefit from this class of drugs.[6, 7] Primary resistance to EGFR-TKIs has been attributed to various factors, including EGFR exon 20 insertion mutations.[8, 9] Patients whose tumors harbor KRAS mutation are rarely responsive to EGFR-TKIs and KRAS mutation might serve as a predictor of resistance to EGFR-TKIs.[10, 11] Activation of alternative signaling pathways including mutations in BRAF, PIK3CA and loss of PTEN have also been implicated as resistance mechanisms in preclinical studies.[12, 13] In addition, germline polymorphisms involving the promoter and intron 1 transcription enhancer regions of the EGFR gene and the ABCG2 multidrug transporter gene have also been reported as modifiers of response to EGFR-TKI therapy.[14-16]

The TORCH (Tarceva OR Chemotherapy) trial was an Italian-Canadian multicenter, open-label, randomized phase III trial comparing first line erlotinib followed by chemotherapy (cisplatin-gemcitabine) at progression, with the reverse standard sequence of first-line chemotherapy (cisplatin-gemcitabine) at progression, with unselected advanced stage IIIB and IV, predominantly Caucasian, NSCLC patients.[17] The study was terminated early due to inferiority of the experimental arm (erlotinib first) in terms of overall survival (OS). In this manuscript, we summarize the results of confirmatory and exploratory analyses of the impact of biomarkers on clinical outcomes in this trial including EGFR gene copy number gains, KRAS mutations, immunohistochemical expression of EGFR family members, cMET and PTEN, and EGFR and ABCG2 germline polymorphisms, in addition to EGFR mutations that have already been partially reported.[17]
the A/C or A/A arm when compared to the C/C arm, led to similar results.

None of the tested biomarkers was prognostic for PFS and OS at the pre-defined significance level of 0.01 (Table 2).

None of the polymorphisms evaluated were significantly associated with skin toxicity or diarrhea (Supplementary Table S15).

DISCUSSION

As an ancillary analysis of the TORCH trial, we explored potential biomarkers for predicting the response or resistance to the EGFR-TKIs compared with chemotherapy. We assessed both biomarker-by-treatment interactions and prognostic value of the proposed biomarkers. Follow-up data were mature and a conservative statistical analysis plan was applied accounting for multiplicity of comparisons and reducing the expected inflation of false positive results. As a major limitation, however, biomarkers’ evaluation was not mandatory in the trial and was actually performed only in 43% of the patients; nonetheless, this rate compares well with other trials in advanced lung cancer where biologic sample collection was not mandatory.

Except for EGFR mutation,[17] we failed to confirm the predictive role of any other biomarker, including high expression of HER2, HER3, cMET and loss of PTEN expression, that were studied due to their potential role in activating bypass survival pathway downstream of EGFR.[18, 19] Among these markers, we found no or very few cases with high expression of HER2 and HER3. Interestingly, the first treatment progression free hazard ratio for high and low cMET expression (H-score ≥200 vs < 200) was 3.04 vs. 1.45, with borderline interaction p value of 0.056. These results confirm that first line chemotherapy is superior to erlotinib irrespective of cMET expression level, however suggesting that any potential activity of erlotinib is significantly less in tumor that express very high level of cMET. Unfortunately, the low number of patients with EGFR mutant tumor exclude us from studying potential role of high MET expression as a potential negative predictive marker in first line EGFR TKI therapy.

The predictive role of EGFR gene copy number as determined by fluorescence in situ hybridization (FISH)

is a matter of controversy.[3, 20-22] As high percentages of EGFR mutant NSCLC also demonstrate amplification of the gene, it was postulated that the predictiveness of EGFR high gene copy number could be accounted by the presence of mutation. In fact, in the IPASS patients, EGFR FISH was not predictive in EGFR wild type patients.[23] The results of our analysis in the TORCH patients confirm this finding (Supplementary Figure S3).

Despite suggestions that germline polymorphisms may be associated with erlotinib efficacy, none has consistently been associated with survival or response.[15, 16] In the TORCH trial, we found a significant interaction between the ABCG2 +42I polymorphism and PFS. The non significant finding of interaction for OS (P = 0.11) may have been favoured by the cross-over design. In this trial, the vast majority of patients likely carried wild type EGFR, which is the primary driver of best initial response. In contrast, wild type EGFR produces mostly stable disease responses, and thus it was unlikely that initial response would be differentiated in this population by genetic polymorphisms; indeed we found no relationship between any of the polymorphisms and best initial response to therapy. Two exploratory analyses of ABCG2 +42I were performed. This ABCG2 polymorphism had been evaluated in one other randomized control trial involving erlotinib as the experimental drug but in a different setting: the BR.21 trial of chemo-refractory placebo-controlled metastatic/advanced stage patients found no significantly interaction associations between this polymorphism and the trial arm for any treatment outcomes.[15] The same polymorphisms may affect toxicity.[15, 24] However, in the TORCH trial, we found no significant or even trends in relationship with any of the main toxicities of erlotinib, but small samples sizes limited any firm conclusions.

In conclusion, an extensive exploratory biomarker analysis in TORCH trial failed to identify additional predictive or prognostic biomarkers beyond EGFR mutation in first line erlotinib therapy.

**MATERIALS AND METHODS**

The details of the TORCH clinical trial eligibility and conduct have been described previously.[17]

![Figure 2: Forest plot of overall survival by treatment arm and biomarkers.](image)

Hazard ratio (HR) < 1 means a lower risk of death for patients treated with first-line erlotinib.
Formalin fixed paraffin embedded blocks or unstained sections of tumor tissue were collected. Because of limited tissue materials, biomarker analyses were performed in the following priority order: EGFR mutation status, KRAS mutation, EGFR gene copy number (GCN) by fluorescent in situ hybridization (FISH), EGFR, cMET, HER2, HER3 and PTEN protein expression by immunohistochemistry. The remaining material was used for genotyping of EGFR and ABCG2 polymorphisms (when no blood sample or tissue block of normal tissue was available). No prioritization was required for blood sample derived DNA.

All biomarker assays were performed at the Applied Molecular Profiling Laboratory at the Princess Margaret Cancer Centre. All tissue analyses were preceded by a pathology review of the hematoxylin eosin (HE) stained slides to confirm the diagnosis, estimate the tumor cell abundance and mark the tumor areas for macrodissection or FISH scoring. The procedure of the EGFR mutation test and EGFR/ABCG2 polymorphism analysis has been described previously.[15, 17, 25]

EGFR exon 19 deletion and exon 21 L858R mutations were analysed as previously reported.[17] KRAS codon 12 and 13 mutations were analysed using the capillary sequencing method, with positive or equivocal results confirmed by repeat sequencing. EGFR gene copy number was evaluated by fluorescence in situ hybridization; high and low copy number cases were categorized using the University of Colorado system, as reported previously.[25]

IHC staining was performed using the BenchMark XT autostainer (Ventana, Tucson, AZ). The antibodies, staining conditions and scoring cut-offs used are detailed in Supplementary Table S1. For each marker, the staining intensity (grades 0 to 3) and estimated percentage (%) of tumor cells at each intensity grade were recorded. The H-score was the sum of % stained tumor cells at each staining intensity. For EGFR, HER2 and HER3, cases were classified as low or high expression, using H-score < 200 and ≥200, respectively. Two scoring systems were used for cMET: (1) MET-H200 scoring system using H-score < 200 and ≥200 as above; and (2) the MET

Figure 3: Forest plot of response by treatment arm and biomarkers. Odds ratio (OR) >1 means a higher probability of response for patients treated with first-line erlotinib.
IHC scoring system that was developed in a previous trial.[26] The latter score was assessed independently by two pathologists (LK and MST) and the final MET-IHC represents the mean of the two independent scores (Supplementary Figure S1). PTEN IHC was interpreted as negative when there was no staining at all.[27] All interpretation was performed without information on clinical outcome and assigned treatment strategy.

Blood samples were collected using a kit provided by the central laboratory with specific processing and shipment instructions. DNA was isolated using the Qiagen humanDNA kit. Polymorphism analyses for EGFR promoter (-216 G>T, rs712829 and -191 C>A rs712830), EGFR intron 1CA repeat polymorphisms and for the ABCG2 +421 C>A (rs2231142) polymorphisms have been described previously.[15, 16] In brief, analyses were conducted using direct Sanger sequencing and Taqman polymerase chain reaction (PCR) reaction. For patients without blood samples, analyses were conducted using DNA isolated from FFPE tumor samples used for mutation analyses, as a surrogate material. Our prior work has shown this region to be highly preserved when comparing germline to somatic material from lung cancer, with >90% agreement in paired blood-tumor tissue analyses.[15, 16]

The statistical analysis plan is detailed in the Supplementary materials on line. Several biomarkers were evaluated in confirmatory (EGFR mutation, EGFR gene copy, EGFR IHC, KRAS mutation, polymorphic variants of EGFR (SNP 216, SNP 191, CA repeat) and ABCG2) and exploratory (PTEN, MET.H200, MET IHC, HER2, HER3) analyses. Because of multiplicity of comparisons different significance levels were used according to a pre-defined step-down Holm-Bonferroni sequential testing procedure.

All efficacy analyses were based on intention-to-treat strategy. The primary end-point was progression-free

### Table 2: Prognostic role of biomarkers with no significant interaction with treatment

| Biomarker | Progression-free survival | Overall survival |
|-----------|---------------------------|-----------------|
|           | Hazard ratio (95% CI)     | Hazard ratio (95% CI) |
|           | P value                   | P value         |
| **EGFR gene copy** |                           |                 |
| High vs low | 0.82 (0.61 – 1.10)       | 0.77 (0.56 – 1.06) |
|            | 0.19                      | 0.11            |
| **EGFR IHC** |                           |                 |
| High vs low | 1.06 (0.64 – 1.77)       | 1.00 (0.58 – 1.72) |
|            | 0.82                      | 0.99            |
| **KRAS mutation** |                           |                 |
| Mutant vs wild type | 1.23 (0.93 – 1.61)       | 1.13 (0.84 – 1.52) |
|            | 0.14                      | 0.42            |
| **PTEN** |                           |                 |
| Positive vs negative | 0.99 (0.65 – 1.51)       | 1.13 (0.71 – 1.81) |
|            | 0.95                      | 0.61            |
| **MET-H200** |                           |                 |
| High vs low | 1.39 (0.99 – 1.95)       | 1.42 (0.99 – 2.05) |
|            | 0.055                     | 0.059           |
| **MET-IHC** |                           |                 |
| Positive vs negative | 1.50 (1.07 – 2.10)       | 1.46 (1.01 – 2.13) |
|            | 0.02                      | 0.047           |
| **EGFR SNP 216** |                           |                 |
| G/G vs T/- | 0.78 (0.59 – 1.03)       | 0.67 (0.48 – 0.94) |
|            | 0.082                     | 0.019           |
| **EGFR SNP 191** |                           |                 |
| C/C vs A/- | 1.13 (0.80 – 1.58)       | 1.19 (0.80 – 1.78) |
|            | 0.49                      | 0.38            |
| **ABCG2** |                           |                 |
| C/C vs A/- | 1.10 (0.78 – 1.57)       | 1.10 (0.73 – 1.66) |
|            | 0.58                      | 0.66            |
| **EGFR CA repeat** |                           |                 |
| S/S vs L/- | 0.94 (0.71 – 1.25)       | 0.89 (0.64 – 1.24) |
|            | 0.67                      | 0.48            |
survival (PFS) to first treatment, while overall survival (OS) and response rate to first treatment (RR) were secondary end-points.

Both predictive and prognostic roles of biomarkers were evaluated using the appropriate multivariable models.

ACKNOWLEDGMENTS

M.Tsao is the M. Qasim Choksi Chair in Lung Cancer Translational Research at the Princess Margaret Cancer Centre/University of Toronto.

CONFLICTS OF INTEREST

M.Tsao and F.Perrone have received research funding from Roche. G.Liu, C.Butter, F.Ciardiello, A.Morabito, F.Perrone and C.Gridelli have received honoraria from AstraZeneca, Boeringher Ingelheim and Roche. A. Rossi has received honoraria from AstraZeneca and Boeringher Ingelheim.

FUNDING

This work was supported by a research grant from the Hoffmann-LaRoche. L.Kim and M.Saieg were supported by the Terry Fox Foundation Special Training Initiative in Health Research for clinician scientists in molecular Oncologic Pathology at CIHR (STP 53912).

Authors contribution

All the authors reviewed the manuscript and agreed to submit it. CG, CB, FC, RF, FP and CG represented the Steering Committee. MDM, CG, SS, GL, MST and FP performed analysis and interpreted data. CB, FC, RF, VG, MAB, YA, AR, NL, PM, AM, CG enrolled and treated patients and provided clinical data.
