Abstract
Let \( G \) be the manifold of all (unparametrized) oriented lines of \( \mathbb{R}^3 \). We study the controllability of the control system in \( G \) given by the condition that a curve in \( G \) describes at each instant, at the infinitesimal level, an helicoid with prescribed angular speed \( \alpha \). Actually, we pose the analogous more general problem by means of a control system on the manifold \( G_\kappa \) of all the oriented complete geodesics of the three dimensional space form of curvature \( \kappa \): \( \mathbb{R}^3 \) for \( \kappa = 0 \), \( S^3 \) for \( \kappa = 1 \) and hyperbolic 3-space for \( \kappa = -1 \). We obtain that the system is controllable if and only if \( \alpha^2 \neq \kappa \). In the spherical case with \( \alpha = \pm 1 \), an admissible curve remains in the set of fibers of a fixed Hopf fibration of \( S^3 \).

We also address and solve a sort of Kendall’s (aka Oxford) problem in this setting: Finding the minimum number of switches of piecewise continuous curves joining two arbitrary oriented lines, with pieces in some distinguished families of admissible curves.

1 Introduction

For \( \alpha \in \mathbb{R} \), the helicoid in standard position in \( \mathbb{R}^3 \) with angular speed \( \alpha \) (or equivalently, with pitch \( 2\pi/\alpha \) if \( \alpha \neq 0 \)) is the parametrized surface
\[
\phi_o : \mathbb{R}^2 \to \mathbb{R}^3, \quad \phi_o(s, t) = s \cos(\alpha t) e_1 + s \sin(\alpha t) e_2 + t e_3.
\]
An helicoid in \( \mathbb{R}^3 \) with angular speed \( \alpha \) is a parametrized surface congruent to \( \phi_o \) by a rigid transformation of \( \mathbb{R}^3 \), that is, a map preserving the distance and the orientation.
Now we state vaguely the problem we are interested in: We fix $\alpha \in \mathbb{R}$. Given two oriented straight lines $\ell_1$ and $\ell_2$ in $\mathbb{R}^3$, can we move $\ell_1$ to $\ell_2$ in such a way that the swept surface resembles at each instant, at the infinitesimal level, an helicoid with angular speed $\alpha$?

This is a control problem which does not arise from a linear or affine linear distribution. Thus, the convenient setting to pose it precisely is the following, that we learned of from [1] (see also Sects. 2.1 in [2] and 2.6 in [8]).

**Definition 1** A **control system** on a smooth manifold $N$ is a fiber subbundle of the tangent bundle $TN$,

$$\mathcal{A} \xrightarrow{\iota} TN \xrightarrow{\downarrow \pi} N.$$ 

A smooth curve $\gamma : (a, b) \rightarrow N$ is said to be **admissible** if $\gamma'(t) \in \iota(\mathcal{A})$ holds for each $t \in (a, b)$. A control system in $N$ is said to be **controllable** if for each pair of points in $N$ there exists a piecewise admissible curve joining them.

Let $\mathcal{G}$ be the space of all oriented straight lines of $\mathbb{R}^3$. This is a four dimensional smooth manifold on which the group of rigid transformations of $\mathbb{R}^3$ acts transitively. The problem above translates into defining a certain subbundle $\mathcal{A}$ of the tangent bundle $T\mathcal{G}$. For the sake of generality, we study it for the three dimensional space forms, that is, we also consider curves in the manifolds of oriented lines in hyperbolic space $H^3$ and of oriented great circles in the sphere $S^3$. We call $\mathcal{G}_\kappa$ the manifold of all oriented geodesics of the three dimensional space form of curvature $\kappa$, in particular, $\mathcal{G} = \mathcal{G}_0$. It is diffeomorphic to $TS^2$ for $\kappa = 0$, $-1$ and to $S^2 \times S^2$ for $\kappa = 1$.

The fiber bundles involved are not trivial. Since the problem is global, this is another reason why we choose the above definition of control system.

Our main result, Theorem 7, asserts the following: For Euclidean space, the system is controllable if and only if $\alpha \neq 0$. In the hyperbolic case, the system is controllable for all $\alpha$, while in the spherical case it is controllable if and only if $\alpha \neq \pm 1$; if $\alpha = \pm 1$, an admissible curve consists of great circles in a Hopf fibration. The precise statement and the proof can be found in Section 2.

Section 3 addresses a related problem: Given a family $\mathcal{F}$ of distinguished curves in a manifold $N$, to find the minimum number of pieces in $\mathcal{F}$ of continuous curves in $N$ joining two arbitrary points in $N$. We call this number the **Kendall number** of $\mathcal{F}$. In fact, this is a problem of the sort David Kendall used to pose to his students in Oxford in the mid-20th century for the system of a sphere rolling on the plane without slipping and spinning (that is, $N$ is the five dimensional manifold of all positions of a sphere resting on a plane) and the family consists of curves in $N$ determined by rolling along straight lines. It was solved by John Hammersley in [10], as a part of a book dedicated to Kendall for his sixty-fifth birthday (see also Sect. 4 of Chap. 4 in [12], where the problem is referred to as the **Oxford problem** and [4] for a more geometric approach).

In our context we can propose two analogues: for the family $\mathcal{F}_\alpha$ of curves in $\mathcal{G}_0$ describing helicoids with angular speed $\alpha$, and the family $\mathcal{H}_\alpha$ of $\alpha$-admissible homogeneous curves in $\mathcal{G}_0$. By these, we mean those $\alpha$-admissible curves which are orbits of monoparametric Lie subgroups of the group of rigid transformations of $\mathbb{R}^3$ (which acts canonically on $\mathcal{G}_0$). We find the Kendall numbers for both families.
2 The $\alpha$-Helicoidal Control System

For $\kappa \in \{0, 1, -1\}$, let $M_\kappa$ be the space form of dimension three with constant Gaussian curvature $\kappa$, that is, $M_0 = \mathbb{R}^3$, $M_1 = S^3$ and $M_{-1} = H^3$. Let $\mathcal{G}_\kappa$ be the space of all complete oriented geodesics in $M_\kappa$ up to parametrizations, i.e.,

$$\mathcal{G}_\kappa = \{ [\sigma] | \sigma : \mathbb{R} \to M_\kappa \text{ is a unit speed geodesic in } M_\kappa \},$$

where $\sigma_1 \sim \sigma_2$ if $\sigma_1 (t) = \sigma_2 (t + t_0)$ for all $t$ and some $t_0 \in \mathbb{R}$.

The isometry group of $M_\kappa$ acts transitively on $\mathcal{G}_\kappa$ and this induces on it a differentiable structure of dimension four, that renders it diffeomorphic to $TS^2$ for $\kappa = 0, -1$ [3], and $S^2 \times S^2$ for $\kappa = 1$ (see Proposition 11). More precisely, for $\kappa = 0$, the map

$$\psi : TS^2 = \{ (v, u) \in S^2 \times \mathbb{R}^3 | u \perp v \} \to \mathcal{G}_0, \quad \psi (v, u) = [ t \mapsto u + sv ], \quad (1)$$

is a diffeomorphism ($v \perp \cong T_v S^2$). It holds that $\psi^{-1} [ t \mapsto u + sv ] = (v, u - \langle u, v \rangle v)$ (here $u$ is not necessarily orthogonal to $v$).

Before presenting the control system that concerns us, we need the following definitions. We denote by $\gamma_0$ the geodesic in $M_\kappa$ with initial velocity $v$.

**Definition 2** Let $\kappa \in \{0, 1, -1\}$ and $\alpha \in \mathbb{R}$. Given $\ell \in \mathcal{G}_\kappa$, $p \in \ell$ and a unit vector $A \in T_p M_\kappa$ orthogonal to $\ell$, the $\alpha$-helicoidal parametrized surface with initial ray $\ell$ and axis $\gamma_A$, $\phi^{\alpha}_{\ell, p, A} : \mathbb{R}^2 \to M_\kappa$, is defined as follows: Suppose that $\ell = [\sigma]$ with $\sigma (0) = p$ and let $B = A \times \sigma' (0)$. Then

$$\phi^{\alpha}_{\ell, p, A} (s, t) = \gamma_{\cos (\alpha t) V_t + \sin (\alpha t) B_t} (s), \quad (2)$$

where $t \mapsto V_t$ and $t \mapsto B_t$ are the parallel vector fields along $\gamma_A$ with initial values $\sigma' (0)$ and $B$, respectively. See Fig. 1.

In other words, the axis begins at $p \in \ell$ with initial velocity $A$ perpendicular to $\ell$, and the rays rotate with constant angular speed $\alpha$ as they move along the axis with unit speed.

![Fig. 1](image-url)
Definition 3 Let $\kappa \in \{0, 1, -1\}$ and $\alpha \in \mathbb{R}$. Given $\ell$, $p$ and $A$ as above, we define the $\alpha$-helicoidal curve with initial ray $\ell$ and axis $\gamma_A$ as

$$
\Gamma_{\ell,p,A}^\alpha : \mathbb{R} \to \mathcal{G}_\kappa, \quad \Gamma_{\ell,p,A}^\alpha (t) = [s \mapsto \phi_{\ell,p,A}^\alpha (s, t)],
$$

and the subset $\mathcal{A}^\alpha_\kappa \subset T\mathcal{G}_\kappa$ by

$$
\mathcal{A}^\alpha_\kappa = \{ \text{initial velocities of } \alpha\text{-helicoidal curves in } \mathcal{G}_\kappa \}.
$$

We call the elements of this set $\alpha$-admissible tangent vectors.

Now we are in the position of defining the $\alpha$-helicoidal control system on $\mathcal{G}_\kappa$, that we present in the following proposition.

Proposition 4 Let $\kappa \in \{0, 1, -1\}$ and $\alpha \in \mathbb{R}$. The canonical projection $\mathcal{A}^\alpha_\kappa \to \mathcal{G}_\kappa$ is a fiber bundle. Moreover, the inclusion $\iota_\alpha : \mathcal{A}^\alpha_\kappa \to T\mathcal{G}_\kappa$ is a fiber subbundle and this gives the control system

$$
\begin{array}{ccc}
\mathcal{A}^\alpha_\kappa & \xrightarrow{\iota_\alpha} & T\mathcal{G}_\kappa \\
\downarrow & & \downarrow \pi \\
\mathcal{G}_\kappa
\end{array}
$$

We will call the admissible curves of this system $\alpha$-admissible curves.

Remark 5 Each curve $\Gamma_{\ell,p,A}^\alpha$ is the orbit of $\ell$ in $\mathcal{G}_\kappa$ under a monoparametric group of isometries of $M_\kappa$, say $t \mapsto g(t)$. However, the vector field $V$ on $\mathcal{G}_\kappa$ induced by the action of this group, that is, $V(l) = \frac{dg}{dt} \big|_0 g(t)(l)$, is not a section of the fiber bundle $\mathcal{A}^\alpha_\kappa \to \mathcal{G}_\kappa$.

The following proposition reinforces the idea that the problem has a global nature and suggests the convenience of working in an invariant setting.

Proposition 6 Let $\kappa \in \{0, 1, -1\}$. If $\alpha^2 \neq \kappa$, the fiber bundle $\mathcal{A}^\alpha_\kappa$ over $\mathcal{G}_\kappa$ is not topologically trivial, that is, the manifold $\mathcal{A}^\alpha_\kappa$ is not homeomorphic to $\mathcal{G}_\kappa \times \mathcal{F}^\alpha_\kappa$, where $\mathcal{F}^\alpha_\kappa$ is the typical fiber of $\mathcal{A}^\alpha_\kappa \to \mathcal{G}_\kappa$.

Examples a) The curves $\Gamma_{\ell,p,A}^\alpha$, i.e. the $\alpha$-helicoidal curves, are clearly $\alpha$-admissible.

b) The homogeneous $\alpha$-admissible curves in the Euclidean case are characterized in Proposition 19. Among them, the curve of straight lines that sweeps a one-sheet hyperboloid is admissible for the control system $(\iota_0^\alpha, \mathcal{A}^\alpha_0)$, for suitable parameters (see the paragraph after that proposition). This also holds for analogous surfaces in $H^3$ and $S^3$.

c) The curve in $\mathcal{G}_0$ associated with a circular helicoid with angular velocity $\alpha \neq 0$ is not $\alpha$-admissible. We recall that this parametrized surface can be built in an analogous manner as $\phi_{\ell,p,A}^\alpha$, but taking a unit speed circle $c$ with initial velocity $A$, centered at a point on $\ell$, instead of $\gamma_A$, and using the normal connection of $c$ to rotate $\ell$ along it, with angular velocity $\alpha$. See Proposition 18.

Now we can state our main result. We recall that a submanifold of a vector space is said to be substantial if it is not included in any affine subspace. The standard Hopf fibration of $S^3$ is the fibration by oriented great circles whose fibers are intersections of $S^3$ with complex lines, identifying $\mathbb{R}^4 \equiv \mathbb{C}^2$. Applying to it isometries of the sphere we have the Hopf fibrations of $S^3$. 

\text{Springer}
Theorem 7 Let $\alpha \in \mathbb{R}$. For $\kappa \in \{0, 1, -1\}$, the following assertions are equivalent:

a) The control system $(\mathcal{A}_\kappa^n, \ell^n_\kappa)$ is controllable.

b) It holds that $\alpha^2 \neq \kappa$.

c) For every $\ell \in \mathcal{G}_\kappa$, the fiber of $\mathcal{A}_\kappa^n$ over $\ell$ is a substantial submanifold of $T_\ell \mathcal{G}_\kappa$.

Moreover, in the Euclidean case, the image of a 0-admissible curve consists of parallel straight lines and in the spherical case, if $\alpha = \pm 1$, the image of an admissible curve consists of great circles in a Hopf fibration.

2.1 Space of Oriented Geodesics

We begin by setting some notations for the three dimensional space forms. In general, we deal with the three cases simultaneously, but the spherical case will need partly a differentiated approach (see Sect. 2.3).

From now on, $\{e_0, e_1, e_2, e_3\}$ denotes the canonical basis of $\mathbb{R}^4$. For $\kappa \in \{0, 1, -1\}$, let $M_\kappa$ be the three dimensional space form with Gaussian curvature $\kappa$, that is, $M_0 = \mathbb{R}^3$ and for $\kappa = \pm 1$, $M_\kappa$ is the connected component of $e_0$ of $\{x \in \mathbb{R}^4 : \langle x, x \rangle_\kappa = \kappa\}$, where

$$\langle x, y \rangle_\kappa = \kappa x_0 y_0 + x_1 y_1 + x_2 y_2 + x_3 y_3,$$

that induces a Riemannian metric on $M_\kappa$. That is, $M_1$ is the sphere $S^3$ and $M_{-1}$ is hyperbolic space $H^3$. To handle the three cases simultaneously, sometimes it will be convenient to identify $\mathbb{R}^3 \equiv e_0 + \mathbb{R}^3 = \{p \in \mathbb{R}^4 : p_0 = 1\}$.

We denote $G_\kappa = \text{Iso}_0(M_\kappa)$, the identity component of the isometry group on $M_\kappa$. Let $O(4)$ and $O(1, 3)$ be the automorphism groups of the inner products $\langle ., . \rangle_1$ and $\langle ., . \rangle_{-1}$, respectively. With the identification $\mathbb{R}^3 \equiv e_0 + \mathbb{R}^3$, it holds that

$$G_0 = \left\{ \begin{pmatrix} 1 & 0 \\ a & A \end{pmatrix} : a \in \mathbb{R}^3, A \in SO(3) \right\},$$

$$G_1 = SO(4) = \{A \in O(4) : \det A = 1\},$$

$$G_{-1} = O_3(1, 3) = \{A \in O(1, 3) : \det A = 1, (A e_0)_0 > 0\}.$$

Given an orthonormal subset $\{u, v\}$ of $T_p M_\kappa$, the cross product $u \times v$ is defined as the unique unit vector $w$ such that $\{u, v, w\}$ is a positively oriented orthogonal basis of $T_p M_\kappa$, that is, $\{p, u, v, w\}$ is a positively oriented orthogonal basis of $(\mathbb{R}^4, \langle ., . \rangle_\kappa)$. For instance, $e_1 \times e_2 = e_3$. It can be extended bilinearly to $T_p M_\kappa \times T_p M_\kappa$.

Next we recall some properties of the space $\mathcal{G}_\kappa$ of oriented geodesics in $M_\kappa$. Their geometry for $\kappa = 0, -1$ has been studied for instance in [5, 9, 16, 17]; for $\kappa = 1$ see Sect. 2.3. The isometry group $G_\kappa$ acts transitively on $\mathcal{G}_\kappa$ through $g \cdot [\sigma] = [g \circ \sigma]$. By abuse of notation, we say that a point $p$ is in $\ell \in \mathcal{G}_\kappa$ if for some parametrization $\sigma$ of $\ell$ there exists $s_\sigma$ such that $p = \sigma(s_\sigma)$.

We introduce the notation

$$\sin_1(r) = \sin r, \quad \sin_0(r) = r, \quad \sin_{-1}(r) = \sinh r, \quad \cos_\kappa(r) = \sin'_\kappa(r)$$

($\kappa \in \{0, 1, -1\}$) and define the geodesic $\sigma_\kappa$ in $M_\kappa$ and the corresponding element $\ell_\kappa$ of $\mathcal{G}_\kappa$ by

$$\sigma_\kappa(s) = \cos_\kappa s e_0 + \sin_\kappa s e_1 \quad \text{and} \quad \ell_\kappa = [\sigma_\kappa].$$
It will be convenient for us to present \( G_\kappa \) explicitly as a homogeneous space. For \( B, C \in \mathbb{R}^{2 \times 2} \), we denote by \( \text{diag} \ (B, C) \) the \( 4 \times 4 \) matrix with blocks \( B \) and \( C \) in the main diagonal. We have:

**Proposition 8** [7] The isotropy subgroup of \( G_\kappa \) at \( \ell_o \) is \( K_\kappa = \{ k(s, t) : s, t \in \mathbb{R} \} \), where

\[
k(s, t) = \text{diag} \ (R_\kappa(s), R_1(t)), \quad \text{with} \quad R_\kappa(t) = \begin{pmatrix} \cos \kappa t & -\kappa \sin \kappa t \\ \sin \kappa t & \cos \kappa t \end{pmatrix}.
\]

We consider on \( G_\kappa \) the differentiable structure induced by the bijection

\[
F : G_\kappa/K_\kappa \rightarrow G_\kappa, \quad F(gK_\kappa) = g \cdot \ell_o.
\]

For \( \kappa \in \{0, 1, -1\} \) we denote by \( g_\kappa \) the Lie algebra of \( G_\kappa \). Also from [7] we have

\[
g_\kappa = \left\{ \begin{pmatrix} 0 & -\kappa x^T \\ x & B \end{pmatrix} : x \in \mathbb{R}^3, B^T = -B \right\}.
\]

The Lie algebra of \( K_\kappa \) is

\[
f_\kappa = \left\{ \text{diag} \ \left( \begin{pmatrix} 0 & -\kappa s \\ s & 0 \end{pmatrix} \right), \begin{pmatrix} 0 & -t \\ t & 0 \end{pmatrix} : s, t \in \mathbb{R} \right\}.
\]

For column vectors \( x, y \in \mathbb{R}^2 \) we call

\[
Z(x, y) = \begin{pmatrix} 0_2 \\ (x, y) \end{pmatrix} \begin{pmatrix} 0_2 \\ (-\kappa x, -y)^T \end{pmatrix}.
\]

The subspace \( p_\kappa = \{ Z(x, y) \in g_\kappa : x, y \in \mathbb{R}^2 \} \) of \( g_\kappa \) is an \( \text{Ad}(K_\kappa) \)-invariant complement of \( f_\kappa \) and there exists a natural identification

\[
d (F \circ \varpi)_I|_{p_\kappa} : p_\kappa \rightarrow T_{\ell_o} G_\kappa,
\]

where \( \varpi : G_\kappa \rightarrow G_\kappa/K_\kappa \) is the canonical projection.

### 2.2 The Fiber Bundle \( \mathcal{A}_\kappa^\alpha \rightarrow G_\kappa \)

Now we consider a particular case of \( \alpha \)-helicoidal curve as in (3), in good position. Let \( \sigma_o \) and \( \ell_o \) be as in (6) and let

\[
p_o = e_0 = \sigma_o(0), \quad A_o = e_3 \quad \text{and} \quad B_o = A_o \times \sigma'_o(0) = e_2.
\]

We call \( \Gamma_\alpha^\sigma \) the curve in \( G_\kappa \) defined by

\[
\Gamma_\alpha^\sigma = \Gamma_\alpha^\sigma|_{p_o, A_o}
\]

and denote by \( X_\alpha \) its initial velocity, that is,

\[
X_\alpha = \left. \frac{d}{dt} \right|_0 \Gamma_\alpha^\sigma(t) \in T_{\ell_o} G_\kappa.
\]
Proof of Proposition 4: We know that $G_\kappa$ acts transitively on the positively oriented orthonormal frame bundle of $M_\kappa$. Then, given $\ell$, $p$, $A$ as in Definition 3, there exists $g \in G_\kappa$ such that $g(e_0) = p$, $d g e_0(e_3) = A$ and sends $\ell_o$ to $\ell$ keeping the orientation. Since clearly $G_\kappa$ carries $\alpha$-helicoidal curves in $\alpha$-helicoidal curves, it turns out that the group $G_\kappa$ acts transitively on $\mathcal{A}_\alpha$. Thus, $\mathcal{A}_\alpha = \{ d g_{\ell_o}(X_\alpha) : g \in G_\kappa \}$; in other words, it is the orbit of $X_\alpha$ in $T\mathcal{G}_\kappa$ under the action of $G_\kappa$ and therefore the inclusion is a fiber subbundle of $T\mathcal{G}_\kappa$. □

We call

$$\xi_\alpha = \begin{pmatrix} 0 & -a_\alpha^\kappa \\ a_\alpha^\kappa & 0 \end{pmatrix} = \begin{pmatrix} 0 & \alpha \\ \kappa & 0 \end{pmatrix} \in p_\kappa,$$

where $Z$ was defined in (8) and $a_\alpha^\kappa = \begin{pmatrix} 0 & \alpha \\ \kappa & 0 \end{pmatrix}$.

Lemma 9 Let $X_\alpha$ be as in (12). Then $d (F \circ \varphi)_I (\xi_\alpha) = X_\alpha$.

Proof For any $t \in \mathbb{R}$, let $S_t \in G_\kappa$ given by

$$S_t = \begin{pmatrix} \cos \kappa t & 0 & 0 & -\kappa \sin \kappa t \\ 0 & \cos \alpha t & -\sin \alpha t & 0 \\ 0 & \sin \alpha t & \cos \alpha t & 0 \\ \sin \kappa t & 0 & 0 & \cos \kappa t \end{pmatrix}.$$ (14)

Then $S_t = \exp (t \xi_\alpha)$, since $S_{t+t} = S_t \circ S_t$ for all $s, t$ and $S_0 = \xi_\alpha$.

Now we check that $S_t \sigma_o(s) = \phi_{\ell_o,p_o,A_o}^\alpha(s,t)$ holds for all $s, t \in \mathbb{R}$. We fix $t$ and verify that both expressions are equal as functions of $s$. Since they are geodesics with the same initial value $\cos \kappa t e_0 + \sin \kappa t e_3$, it suffices to see that they have the same initial velocity. We compute

$$\frac{d}{ds} \bigg|_0 S_t \sigma_o(s) = S_t \frac{d}{ds} \bigg|_0 \sigma_o(s) = S_t e_1 = \cos (\alpha t) e_1 + \sin (\alpha t) e_2,$$

which coincides with

$$\frac{d}{ds} \bigg|_0 \phi_{\ell_o,p_o,A_o}^\alpha(s,t) = \frac{d}{ds} \bigg|_0 \gamma_{\kappa \alpha} \sigma_o(s) = \cos (\alpha t) V_t + \sin (\alpha t) B_t,$$

as desired. Finally,

$$d (F \circ \varphi)_I (\xi_\alpha) = d (F \circ \varphi)_I (S_0) = \frac{d}{dt} \bigg|_0 F \circ \varphi \circ S_t = \frac{d}{dt} \bigg|_0 S_t [\sigma_o],$$

which equals $\frac{d}{dt} \bigg|_0 \Gamma_\alpha (t) = X_\alpha$ by the computation above. □

Proposition 10 a) Under the identification (9), the fiber of $\mathcal{A}_\alpha$ over $\ell_0$ is

$$\text{Ad}(K_\kappa)(\xi_\alpha) = \{ \text{Ad}(k(s,t))(\xi_\alpha) : s, t \in \mathbb{R} \},$$

with $k(s, t)$ as in (7).

b) If $v \in \mathcal{A}_\alpha$, then $-v \in \mathcal{A}_\alpha$.

c) For $\kappa \in \{0, -1\}$ and $\alpha \neq 0$, $G_\kappa$ acts simply transitively on $\mathcal{A}_\alpha$.

Proof a) We know from the proof of Proposition 4 that $G_\kappa$ acts transitively on $\mathcal{A}_\alpha$ via the differential. Hence, the fiber of $\mathcal{A}_\alpha$ over $\ell_0$ equals $\{ d k_{\ell_0}(X_\alpha) : k \in K_\kappa \}$. The assertion
follows now from the lemma above and the commutativity of the diagram

\[
\begin{array}{ccc}
\mathcal{G}_\kappa & \xrightarrow{\Ad(k)} & \mathcal{G}_\kappa \\
d(F \circ \varpi)_I|_{p_\kappa} & \downarrow & d(F \circ \varpi)_I|_{p_\kappa} \\
T_{\ell_\alpha}\mathcal{G}_\kappa & \xrightarrow{dk_p} & T_{\ell_\alpha}\mathcal{G}_\kappa.
\end{array}
\] (15)

b) By homogeneity, we may suppose that \( v \) is in the fiber over \( \ell_\alpha \). Hence \( v \) has the form

\[
\Ad\left(k(s,t)\right)(\xi_\alpha) = \begin{pmatrix} 0_2 & -R_\kappa(s)\left(a^\alpha_1\right)^T R_1(-t) \\ R_1(t) a^\alpha_1 R_\kappa(-s) & 0_2 \end{pmatrix}.
\] (16)

Since \( R_1(t + \pi) = R_1(\pi) R_1(t) = -R_1(t) \), we have that \( -v = \Ad\left(k(s,t + \pi)\right)(\xi_\alpha) \) and so it belongs to the fiber over \( \ell_\alpha \).

c) Let \( H_\kappa(\alpha) \) be the isotropy subgroup at \( X_\alpha \) of the action of \( G_\kappa \) on \( A_\alpha^\kappa \). We have that

\[ H_\kappa(\alpha) = \{ k \in K_\kappa | dk_{\ell_\alpha} X_\alpha = X_\alpha \}, \]

which by the diagram (15) equals

\[ \{ k \in K_\kappa | \Ad(k)(\xi_\alpha) = k\xi_\alpha k^{-1} = \xi_\alpha \}. \]

Now, by (16), \( k(s,t) \in K_\kappa \) commutes with \( \xi_\alpha \) if and only if \( R_1(t) a^\alpha_1 = a^\alpha_1 R_\kappa(s) \), that is,

\[
\begin{pmatrix} -\sin t & \alpha \cos t \\ \cos t & \alpha \sin t \end{pmatrix} = \begin{pmatrix} \alpha \sin_\kappa s & \alpha \cos_\kappa s \\ \cos_\kappa s & -\kappa \sin_\kappa s \end{pmatrix}.
\]

Therefore, \( k(s,t) \in H_\kappa(\alpha) \) if and only if

\[-\sin t = \alpha \sin_\kappa s, \quad \cos t = \cos_\kappa s \quad \text{and} \quad \alpha \sin t = -\kappa \sin_\kappa s.\]

If \( \kappa = 0 \), this implies that \( \cos t = 1 \) and \( -\sin t = \alpha s \), and so \( R_\kappa(s) = R_1(t) = I \). If \( \kappa = -1 \), we have that \( \cos t = \cosh s = 1 \) and so we arrive at the same conclusion. In both cases, \( H_\kappa(\alpha) = \{ I \} \), as desired.

\[ \square \]

2.3 The \( \alpha \)-Helicoidal Control System in the Spherical Case

Let \( \mathbb{H} \) be the skew field of quaternions. We consider the sphere \( S^3 \) as the set of unit quaternions, that is, \( S^3 = \{ q \in \mathbb{H} | |q| = 1 \} \), which is a Lie group. It is well known that, identifying \( \mathbb{R}^4 \) with \( \mathbb{H} \), the maps \( f : S^3 \to SO(3) \) and \( F : S^3 \times S^3 \to SO(4) \) given by

\[
f(p)(x) = px\overline{p} \quad \text{and} \quad F(p,q)(y) = pyq,
\] (17)

for \( x \in \text{Im}(\mathbb{H}) \cong \mathbb{R}^3 \) and \( y \in \mathbb{H} \cong \mathbb{R}^4 \), are both surjective two-to-one morphisms.

Now, \( \mathcal{G}_1 \) is the manifold of all oriented great circles of \( S^3 \). We have that \( S^3 \times S^3 \) acts transitively on \( \mathcal{G}_1 \), since the action of \( SO(4) \) on it is transitive.

It is well known, for instance from [6] and [15], that \( \mathcal{G}_1 \) is diffeomorphic to \( S^2 \times S^2 \).

We include this assertion in the next proposition and write down the proof since it is different from the ones given in those articles and shorter; also, it contributes to establish the nomenclature used later. Note that \( S^1 = \{ e^{it} | t \in \mathbb{R} \} \subset S^3 \).

**Proposition 11** The transitive action of \( S^3 \times S^3 \) on \( \mathcal{G}_1 \) has \( S^1 \times S^1 \) as its isotropy subgroup at \( c_\alpha = [s \mapsto e^{is}] \) and induces the (well defined) diffeomorphism

\[
\Phi : \mathcal{G}_1 \to S^2 \times S^2, \quad \Phi((p,q) \cdot c_\alpha) = (f(p)(i), f(q)(i)).
\] (18)
Let \((p, q) \in S^1 \times S^1\). Then \(p = e^{it}\) and \(q = e^{ir}\) for some \(t, r \in \mathbb{R}\). Thus, \(s \mapsto p e^{is} \overline{q} = e^{i(s+t-r)}\) belongs to the equivalence class \([s \mapsto e^{is}]\) and so \(S^1 \times S^1\) is included in the isotropy subgroup. Now, we check the other inclusion. Let \(p, q \in S^3\) such that \(p e^{is} \overline{q} = e^{i(s+s_0)}\) for some \(s_0\) and all \(s\). Then, \(p e^{is} = e^{i(s_0)} q\) for all \(s\) and in particular, \(p = e^{i[s]} q\). Differentiating, we have \(p i e^{is} = i e^{is} e^{i[s]} q\) and so, \(p i = i e^{is} q = i p\). Since \(p\) commutes with \(i\), then \(p \in S^1\) and so \(q = e^{-i[s]} p \in S^1\) as well. Therefore, the isotropy subgroup at \(c_o\) is \(S^1 \times S^1\).

Now \((S^3 \times S^3) / (S^1 \times S^1)\) is canonically diffeomorphic to \((S^3/S^1) \times (S^3/S^1)\). Then the expression for \(\Phi\) follows from the fact that the morphism \(f\) in (17) induces a transitive action of \(S^3\) on \(S^2 \subset \text{Im} \mathbb{H}\), given by \((p, u) \mapsto \overline{pu} \overline{p}\), with isotropy subgroup at \(i\) equal to \(S^1\).

Now, we describe in terms of the identification \(\Phi\) above the curve \(\Gamma^\alpha_o\) in \(\mathcal{G}_1\) in good position defined in (11). Given \(\beta, \tau \in \mathbb{R}\), we define the isometries

\[
R_\beta (q) = e^{\beta k/2} q e^{-\beta k/2} \quad \text{and} \quad T_\tau (q) = e^{\epsilon k/2} q e^{\epsilon k/2}
\]

of \(S^3\) (see (17)). The former is a rotation of \(\mathbb{R}^3\) fixing \(1\) and \(k\), and rotating the \(i\)-\(j\) plane through the angle \(\beta\). The latter is a transvection in \(\tau\) along \(t \mapsto e^{i\epsilon k}\) (i.e. \(T_\tau (e^{i\epsilon}) = e^{(i+\tau)\epsilon}k\) and its differential realizes the parallel transport along \(t \mapsto e^{i\epsilon k}\), see for instance Theorem 2 (3) in Note 7 of [13]). Notice that \(R_\beta\) and \(T_\tau\) commute.

**Proposition 12**

a) The \(\alpha\)-helicaloid surface in \(S^3\) with axis \(t \mapsto e^{i\epsilon}\) and initial circle \(s \mapsto e^{is}\) is given by \(\phi_o (s, t) = T_t R_{\alpha t} (e^{i\epsilon})\).

b) For the corresponding curve \(\Gamma^\alpha_o\) in \(\mathcal{G}_1\), the associated curve in \(S^2 \times S^2\) is

\[
(\Phi \circ \Gamma^\alpha_o) (t) = \left( R_{t(1+\alpha)} (i), R_{t(-1-\alpha)} (i) \right).
\]

In particular,

\[
(\Phi \circ \Gamma^\alpha_o)' (0) = \left( (1 + \alpha) j, (1 - \alpha) j \right) \in T_{(i, i)} \left( S^2 \times S^2 \right).
\]

c) The fiber of \(\omega^\alpha_o\) over \((x, y) \in S^2 \times S^2\), via the identification \(\Phi\), is given by

\[
\{(1 + \alpha) z, (1 - \alpha) w) : z, w \in \text{Im} \mathbb{H}, |z| = |w| = 1, z \perp x \text{ and } w \perp y\}.
\]

**Proof**

The first assertion follows from the properties of \(R_\beta\) and \(T_\tau\) we mentioned when we introduced them above. It implies that

\[
\Gamma^\alpha_o (t) = \left[ s \mapsto T_t R_{\alpha t} (e^{i\epsilon}) \right] = \left[ s \mapsto e^{i\epsilon k/2} e^{\alpha t k/2} e^{i\epsilon} e^{-\alpha t k/2} e^{i\epsilon k/2} \right] = (p_t, q_t) \cdot c_o,
\]

where \(p_t = e^{((1+\alpha)t)k/2}\), \(q_t = e^{(1-\alpha)t k/2}\). Then, \((\Phi \circ \Gamma^\alpha_o) (t) = (p_t \overline{p_t}, q_t \overline{q_t})\) and (19) follows. A straightforward computation yields (20).

Now we verify (c). By homogeneity we may suppose \(x = y = i\). As we saw in the proof of Proposition 4, the group \(G_1 = SO (4)\) acts transitively on \(\omega^\alpha_o\). Since \(S^3 \times S^3\) covers \(SO (4)\), we may write \(\omega^\alpha_o = \{ p \Gamma^\alpha_o (0) \overline{q} : p, q \in S^3 \}\).

By Proposition 11, the isotropy subgroup of the action of \(S^3 \times S^3\) on \(S^2 \times S^2 \simeq \mathcal{G}_1\) is \(S^1 \times S^1\). Thus, the fiber of \(\omega^\alpha_o\) over \(c_o \simeq (i, i)\) is \(\{ p \Gamma^\alpha_o (0) \overline{q} : p, q \in S^1 \}\) and using (20) we get that it equals

\[
\{(1 + \alpha) p j \overline{p}, (1 - \alpha) q j \overline{q}) : p, q \in S^1 \}.
\]

Now, putting \(p = e^{i\epsilon t}\), we have \(p j \overline{p} = e^{i\epsilon} e^{-i\epsilon t} = \cos (2t) j + \sin (2t) k\), which are exactly the unit elements on \(\text{Im} \mathbb{H}\) orthogonal to \(i\). Thus, (21) follows.
Next we recall the concept of Hopf fibration. The left multiplication by \( i \) in \( \mathbb{H} \) induces on it a vector space structure over \( \mathbb{C} \). We have that \( \{ \mathbb{C}q \cap S^3 \mid q \in S^3 \} \), the set formed by all the intersections of complex lines with the sphere, is the set of fibers of a fibration of \( S^3 \) by oriented great circles, which is known as the **standard Hopf fibration**. Any fibration congruent to it by an isometry of \( S^3 \) (which does not necessarily preserve the orientation) is called a **Hopf fibration**.

The following proposition is known, for instance, from [6]. For the reader’s convenience we give a proof in the framework on this subsection.

**Proposition 13** A subset \( A \) of \( \mathcal{G}_1 \) consists of all the fibers of a Hopf fibration if and only if \( \Phi (A) = S^2 \times \{ z \} \) or \( \Phi (A) = \{ z \} \times S^2 \) for some \( z \in S^2 \).

**Proof** As above, let \( c_o = [s \mapsto e^{is}] \). The standard Hopf fibration has fibers \( c_o q \), with \( q \in S^3 \). By (17), the elements of \( O (4) \) have either the form \( q \mapsto p_1 q \overline{p_2} \) (those preserving orientation) or the form \( q \mapsto p_1 \overline{q} \overline{p_2} \) (those inverting orientation), with \( p_1, p_2 \in S^3 \). Then, the set of fibers of a Hopf fibration has the form \( H_l \) or \( H_r \), where

\[
H_l = \{ p_1 c_o q \overline{p_2} \mid q \in S^3 \} \quad \text{and} \quad H_r = \{ p_1 \overline{c_o q} \overline{p_2} \mid q \in S^3 \}.
\]

Now,

\[
H_l = \{ p_1 c_o q \mid q \in S^3 \} = \{ (p_1, q) \cdot c_o \mid q \in S^3 \}
\]

and hence \( \Phi (H_l) = \{ (p_1 i \overline{p_1}, q i \overline{p_1}) \mid q \in S^3 \} = \{ z \} \times S^2 \), with \( z = p_1 i \overline{p_1} \), since \( q \mapsto f (q) (i) \) is onto \( S^2 \). On the other hand, we have that \( \overline{c_o} = [s \mapsto e^{-is}] = j c_o (-j) \) and so

\[
p_1 \overline{c_o q} \overline{p_2} = p_1 \overline{q} \overline{c_o} \overline{p_2} = p_1 \overline{q} j c_o (-j) \overline{p_2} = p_1 \overline{q} j c_o \overline{p_2} j = (p_1 \overline{q} j, p_2 j) \cdot c_o.
\]

Proceeding as for \( H_l \), we have then that \( \Phi (H_r) = S^3 \times \{ z \} \) with \( z = -p_2 i \overline{p_2} \).

### 2.4 Proofs of the Results of This Section

**Proposition 14** For \( \kappa = 0, 1 \) and \( \alpha^2 = \kappa \), the system \((\mathcal{X}^\alpha, \mathcal{L}^\kappa_\alpha)\) is not controllable. Moreover, either if \( \kappa = 0 \) and \( \alpha = 0 \), or if \( \kappa = 1 \) and \( \alpha = \pm 1 \), a piecewise \( \alpha \)-admissible curve in \( \mathcal{G}_\kappa \) consists of parallel straight lines or of great circles in a Hopf fibration, respectively.

**Proof** First we consider the Euclidean case with \( \alpha = 0 \). Let \( t \mapsto \ell_t \) be a 0-admissible curve in \( \mathcal{G}_0 \). For each \( t \) there exist \( p_t \in \ell_t \) and \( A_t \) such that \( \frac{d}{dt} \ell_t = \Gamma_t' (0) \), with \( \Gamma_t = \Gamma_{\ell_t, p_t, A_t} \), that is,

\[
\Gamma_t (\tau) = [s \mapsto \phi_{\ell_t, p_t, A_t} (s, \tau) = p_t + \tau A_t + s v_t],
\]

where \( v_t \in S^2 \) is the direction of \( \ell_t \), in particular, \( v_t \perp A_t \). Via the diffeomorphism \( \psi : T S^2 \to \mathcal{G}_0 \) in (1) and recalling the expression for its inverse given afterwards, we have

\[
\psi^{-1} (\ell_t) = (v_t, p_t - \langle p_t, v_t \rangle v_t) \quad \text{and} \quad \psi^{-1} \Gamma_t (\tau) = (v_t, p_t + \tau A_t - \langle p_t, v_t \rangle v_t).
\]

Now \( \frac{d}{dt} \ell_t \bigg|_0 = \frac{d}{dt} \bigg|_0 \Gamma_t (\tau) \) implies that \( \frac{d}{dt} \bigg|_0 \psi^{-1} (\ell_t) = \frac{d}{dt} \bigg|_0 (\psi^{-1} \Gamma_t) (\tau) \). Comparing the first coordinates we obtain \( v_t' = 0 \). Therefore the curve \( \ell_t \) consists of parallel lines and in particular the system is not controllable.
In order to deal with the spherical case we use the identification $\mathcal{G}_1 \cong S^2 \times S^2$ introduced in (18). Suppose that $\alpha = 1$ and let $\gamma = (\gamma_1, \gamma_2)$ be a piecewise admissible curve in $S^2 \times S^2$. Then, the velocity $\gamma'(t)$ of each piece of $\gamma$ is in the fiber of $\mathcal{A}^1_1$ over $\gamma(t)$, which by (21) is included in $T_{\gamma(t)} S^2 \times \{0_{\gamma(t)}\}$. Thus, $\gamma'_2 = 0$ and then $\gamma_2$ is constant, say $\gamma_2 \equiv y_o$. So, the curve $\gamma$ lies in $S^2 \times \{y_o\}$, that consists of the fibers of a Hopf fibration, as we saw in Proposition 13. Hence, two oriented circles cannot be joined by a piecewise 1-admissible curve if they do not share the projection onto the second factor. So, the system is not controllable. If $\alpha = -1$ a similar argument applies, involving $\{x_o\} \times S^2$. □

Proposition 15 Let $\kappa \in \{0, 1, -1\}$. For any $\ell \in \mathcal{G}_\kappa$, the fiber of $\mathcal{A}^\kappa_1$ over $\ell$ is a substantial submanifold of $T\ell \mathcal{G}_\kappa$ if and only if $\alpha^2 \neq \kappa$.

Proof Recall that a submanifold $N$ of a vector space $W$ is said to be substantial if it is not included in any proper affine subspace of $W$. If $N$ is central symmetric, that is $-N = N$, we can substitute subspace for affine subspace, since the segment joining two opposite vectors in $N$ contains the origin. If $W$ is additionally endowed with an inner product $\langle \cdot, \cdot \rangle$, then $N$ is substantial if and only if $\langle q, u \rangle = 0$ for every $q \in N$ only when $u = 0$.

Now we prove the statement of the proposition. By homogeneity, we may suppose that $\ell = \ell_o$. By Proposition 10 (a) and (b), it suffices to show that $\text{Ad}(K_\kappa) (\xi_{\alpha})$ is not contained in a proper subspace of $p_\kappa$. On this vector space we consider the inner product

$$\langle Z (X,Y) , Z (U, V) \rangle = \langle X, U \rangle + \langle Y, V \rangle$$

(see (8)). Let $\zeta = Z \begin{pmatrix} x \\ w \\ z \\ y \end{pmatrix} \in p_\kappa$ and define $f_{\zeta} : \mathbb{R}^2 \to \mathbb{R}$ by

$$f_{\zeta} (s, t) = \langle \text{Ad} (k (s,t)) (\xi_\alpha), \zeta \rangle,$$

where $k (s,t) \in K_\kappa$ is as in (7).

Suppose that $f_{\zeta} \equiv 0$. Then $\frac{\partial f_{\zeta}}{\partial s} \equiv \frac{\partial f_{\zeta}}{\partial t} \equiv 0$ holds and a straightforward computation using (16) gives

$$\frac{\partial f_{\zeta}}{\partial s} (s, 0) = \cos s \ (\alpha y - x) + \sin s \ (-\alpha z - w) = 0,$$

$$\frac{\partial f_{\zeta}}{\partial t} (s, 0) = \cos s \ (\kappa y - \alpha x) + \sin s \ (-\alpha w - \kappa z) = 0.$$

By the linear independence of cos and sin we obtain the linear system

$$\alpha y - x = 0, \ \kappa y - \alpha x = 0, \ -\alpha z - w = 0, \ -\alpha w - \kappa z = 0.$$

Now, if $\alpha^2 \neq \kappa$, the system has only the trivial solution and so $\zeta = 0$. Thus, in this case, the submanifold is substantial.

Finally, the submanifold is not substantial if $\alpha^2 = \kappa$, since for $\zeta = Z \begin{pmatrix} \alpha \\ 1 \\ -\alpha \end{pmatrix}$, a lengthy computation yields $f_{\zeta} \equiv 0$. □

Now we present the proof of the main result.

Proof of Theorem 7 By Proposition 14, we have that (a) implies (b) and that the last assertion of the theorem is true. The equivalence between (b) and (c) was proved in the previous proposition.
Now we verify that (c) implies (a). We apply Sussmann’s Orbit Theorem [18] (we also consulted [14]). We begin by showing the existence of a smooth vector field family $D$ defined everywhere whose $D$-orbits are the whole manifold. Since $\mathcal{O}_a^\alpha \to \mathcal{G}_k$ is a fiber bundle with typical fiber $\mathcal{F}_k^a$ we can take trivializations $U_i \times \mathcal{F}_k^a \to \pi^{-1}(U_i)$ ($i \in \mathcal{I}$) in such a way that the union of all $U_i$ covers $\mathcal{G}_k$. Let

$$D = \{\text{smooth sections } v^i : U_i \to \pi^{-1}(U_i), i \in \mathcal{I}\},$$

(22)

which is a smooth vector field family defined everywhere. We have to show that its $D$-orbits are the whole manifold.

Let $\Delta_D$ be the distribution on $\mathcal{G}_k$ defined as follows: $\Delta_D(\ell)$ is the subspace of $T_\ell \mathcal{G}_k$ spanned by all $v(\ell)$ such that $v \in D$ and $v$ is defined on $\ell$. Hence, the fiber of $\mathcal{O}_a^\alpha$ over $\ell$ is contained in $\Delta_D(\ell)$. Since $\alpha^2 \neq \kappa$, we have by Proposition 15 that $\Delta_D(\ell) = T_\ell \mathcal{G}_k$ for all $\ell$. Then the smallest $D$-invariant distribution containing $\Delta_D$ coincides with $T\mathcal{G}_k$. By the Orbit Theorem, the $D$-orbit of any $\ell \in \mathcal{G}_k$ is the whole $\mathcal{G}_k$.

Finally, notice that if $v \in D$ is as in (22), then $-v$ is also in $D$ by Proposition 10 (b). This implies that the system is controllable. Indeed, let $\ell_0, \ell' \in \mathcal{G}_k$ and $v^i \in D$ ($i = 1, \ldots, k$) such that $v^i_t \cdots v^i_{t_0}(\ell_0) = \ell'$, where $t \mapsto v^i_t$ denotes the flow of $v^i$. Call $\ell_i = v^i_t(\ell_{i-1})$ and suppose that $t_j < 0$ and $\gamma^j : [t_j, 0] \to \mathcal{G}_k$ is the integral curve of $v^j$ with $\gamma^j(0) = \ell_{j-1}$. If $\gamma^j : [0, -t_j] \to \mathcal{G}_k$ is the integral curve of $-v^j$ with $\gamma^j(0) = \ell_{j-1}$, then $\gamma^j(-t_j) = \ell_j$. □

**Proof of Proposition 6** We begin by describing the typical fibers. We consider first the cases $\kappa = 0, -1$. Since $\alpha^2 \neq \kappa$, we know from the proof of Proposition 10 that the fiber over $\ell_o$ can be identified with $K_k$. Hence, $\mathcal{F}_k^a$ is homeomorphic to the cylinder by (7). When $\kappa = 1$ and $\alpha^2 \neq 1$, we have by (21) that $\mathcal{F}_k^a$ is homeomorphic to $S^1 \times S^1$.

To see that $\mathcal{O}_a^\alpha$ and $\mathcal{G}_k \times \mathcal{F}_k^a$ are not homeomorphic we show that their fundamental groups do not coincide.

First we deal with the cases $\kappa = 0, -1$. By Proposition 10, we can identify $\mathcal{O}_a^\alpha = G_k$. By (5), we have

$$\pi_1(\mathcal{O}_a^\alpha) = \pi_1(G_0) = \pi_1(SO(3) \times \mathbb{R}^3), \quad \pi_1(\mathcal{O}_a^{\kappa = 1}) = \pi_1(G_{-1}) = \pi_1(O_o(1, 3)),$$

both equal to $\pi_1(SO(3)) = \mathbb{Z}_2$. On the other hand, $\mathcal{G}_k$ is homeomorphic to $T S^2$, which is a deformation retract of $S^2$ and in particular, simply connected. Thus,

$$\pi_1(\mathcal{G}_k \times \mathcal{F}_k^a) = \pi_1(T S^2 \times \mathbb{R} \times S^1) = \pi_1(S^1) = \mathbb{Z} \neq \mathbb{Z}_2.$$

For the case $\kappa = 1$ and $\alpha \neq \pm 1$, we know from Proposition 11 that $\mathcal{G}_k$ is diffeomorphic to $S^2 \times S^2$ and also that $\mathcal{F}_k^a = S^1 \times S^1$, by Proposition 12 (c). Then $\pi_1(\mathcal{G}_k \times \mathcal{F}_k^a) = \mathbb{Z} \times \mathbb{Z}$. By Proposition 4, $\mathcal{O}_a^\alpha$ is the orbit of $X_a = (G_a^\alpha)^{(0)}$ by the action of $SO(4)$, which is covered by $S^3 \times S^3$ (see (17)). By (20), $\mathcal{O}_a^\alpha$ is homeomorphic to $(S^3 \times S^3) / H$, where $H$ is the isotropy subgroup at $((1 + \alpha) j, (1 - \alpha) j) \in T_0(0, 0)$ $(S^2 \times S^2)$. Now, $H$ consists of all the elements $(p, q) \in S^3 \times S^3$ that fix both the foot point $(i, i)$ and $(j, j)$, since $\alpha^2 \neq 1$. We have that $pi \overline{p} = qj \overline{q} = i$ and $pj \overline{p} = qj \overline{q} = j$ if and only if $p = \pm 1$ and $q = \pm 1$. Then

$$\mathcal{O}_a^\alpha = S^3 \times S^3 / \{(\epsilon, \delta) : \epsilon, \delta = \pm 1\},$$

which is homeomorphic to $\left((S^3 / \{\pm 1\}) \times (S^3 / \{\pm 1\})\right) = \mathbb{R} P^3 \times \mathbb{R} P^3$, whose fundamental group is $\mathbb{Z}_2 \times \mathbb{Z}_2 \neq \mathbb{Z} \times \mathbb{Z}$. □
2.5 Examples

In this subsection we give examples of \(\alpha\)-admissible curves. Since we have already dealt with various features of the spherical case, we concentrate on the Euclidean and hyperbolic cases. We relate \(\alpha\)-admissible curves to Jacobi fields and use that to describe all the homogeneous \(\alpha\)-admissible curves for \(\kappa = 0\) (we recall from the introduction that a curve \(\beta\) in \(\mathcal{G}_0\) is homogeneous if there exists a Lie subgroup \(g : \mathbb{R} \to G_0\) such that \(\beta (t) = g (t) \beta (0)\) for all \(t\)). This provides nontrivial examples, which, in their turn, constitute an interesting family to pose Kendall’s problem.

Let \(\sigma\) be a unit speed geodesic of \(M_\kappa\), \(\kappa \in \{0, 1, -1\}\). A Jacobi field along \(\sigma\) arises from geodesic variations as follows: Let \(\varphi : \mathbb{R} \times (-\varepsilon, \varepsilon) \to M_\kappa\) be a smooth map such that for each \(t \in \mathbb{R}\), \(s \mapsto \varphi (s, t) =_\text{def} \varphi_t (s)\) is a unit speed geodesic with \(\varphi_0 = \sigma\). Then the associated Jacobi field \(J\) along \(\sigma\) is given by \(J (s) = \frac{d}{dt}|_0 \varphi_t (s)\).

Jacobi fields \(J\) arising from unit speed geodesic variations are exactly those with \(\frac{DJ}{dt} \perp \sigma'\) (or equivalently, with \(b = 0\) in the expression (23)). We call \(\mathcal{J}_\sigma\) the vector space consisting of all such Jacobi fields along \(\sigma\). There is a canonical surjective linear morphism

\[
\mathcal{T}_\sigma : \mathcal{J}_\sigma \to T_{[\sigma]} \mathcal{G}_\kappa, \quad \mathcal{T}_\sigma (J) = \frac{dJ}{dt}|_0 [\sigma],
\]

where \(\sigma_t\) is any variation of \(\sigma\) by unit speed geodesics, associated with \(J\) (see Sect. 2 in [11]). The kernel of \(\mathcal{T}_\sigma\) is spanned by \(\sigma'\). It is convenient for us to work with the surjection \(\mathcal{T}_\sigma\) instead of the more common isomorphism defined on the space of Jacobi fields along \(\sigma\) which are orthogonal to \(\sigma'\) (see for instance [17] for the hyperbolic case). This is due to the type of geodesic variations appearing in the examples. By a usual abuse of notation, we sometimes write \(J' = \frac{dJ}{dt}\).

**Proposition 16** Fix \(\alpha \neq 0\) and let \(J \in \mathcal{J}_\sigma\) with \(J (0) \perp J' (0)\). If

\[
\| J' (0) \| = |\alpha| \quad \text{and} \quad J' (0) = \alpha J (0) \times \sigma' (0),
\]

then \(\mathcal{T}_\sigma (J)\) is \(\alpha\)-admissible. Moreover, the converse is true if \(\kappa = 0, -1\). See Fig. 2.

**Proof** Let \(\ell = [\sigma], p = \sigma (0)\) and \(A = J (0) - [J (0), \sigma' (0)] \sigma' (0)\), which has unit norm since

\[
|\alpha| = \| J' (0) \| = \| \alpha J (0) \times \sigma' (0) \| = |\alpha| \| A \times \sigma' (0) \| = |\alpha| \| A \|. \]

To prove the first assertion, it suffices to verify that

\[
\mathcal{T}_\sigma (J) = \frac{d}{dt}|_0 [s \mapsto \phi_{\ell, p, A} (s, t)],
\]
or equivalently, that the Jacobi field $L$ along $\sigma$ associated with the variation $\phi_{\ell,p,A}^\alpha$ satisfies $\mathcal{T}_\sigma (L) = \mathcal{T}_\sigma (J)$. We compute

$$L (0) = \frac{d}{ds} \bigg|_0 Y_{\cos (at)V_t + \sin (at)B_t} (0) = \frac{d}{ds} \bigg|_0 Y_A (t) = A.$$ 

Also, since $\frac{D}{ds} \bigg|_0 \frac{d}{ds} \bigg|_0 Y_{\cos (at)V_t + \sin (at)B_t} (s) = \frac{D}{ds} \bigg|_0 \cos (at) V_t + \sin (at) B_t = \alpha B. \quad (26)$

On the other hand, $\alpha B = \alpha A \times \sigma' (0) = \alpha J (0) \times \sigma' (0) = J' (0)$. Therefore, $L (0) = J' (0)$ and $L (0)$ differs from $J (0)$ by a multiple of $\sigma' (0)$. Thus, $\mathcal{T}_\sigma (L) = \mathcal{T}_\sigma (J)$.

Next we prove the converse for $\kappa = 0, -1$. We consider $J$ as in (23) with $b = 0$ and notice that $J (0) = u + \alpha \sigma' (0) \perp J'(0) = v$. Hence $u \perp v$ and so $U (s) \perp V (s)$ for all $s$.

Suppose that $\mathcal{T}_\sigma (J)$ is admissible, that is, $\mathcal{T}_\sigma (J) \in \mathcal{K}_\ell^\alpha$. Since $\mathcal{T}_\sigma (J) \in T_{\ell} M_\ell$, there exist $p \in \ell$ and a unit vector $A \in T_p M_\ell$ orthogonal to $\ell$ such that $\mathcal{T}_\sigma (J) = \frac{d}{dt} \bigg|_0 \Gamma_{\ell,p,A} (t)$ (here, $p$ and $A$ are different from the point and the vector with those names in the first part of the proof). Let $s_o \in \mathbb{R}$ such that $\sigma (s_o) = p$. Putting $\mathcal{T} (s) = \frac{d}{dt} \bigg|_0 \phi_{\ell,p,A}^\alpha (s,t)$, we have that $s \mapsto \mathcal{T} (s - s_o) \in \mathcal{F}_\sigma$ and its image under $\mathcal{T}_\sigma$ equals $\mathcal{T}_\sigma (J)$. Since $\mathcal{T}_\sigma$ is a surjective morphism, $J (s) = \mathcal{T} (s - s_o) + c \sigma' (s)$ holds for some $c \in \mathbb{R}$. Then

$$J (s_o) = \mathcal{T} (0) + c \sigma' (s) = \frac{d}{dt} \bigg|_0 \phi_{\ell,p,A}^\alpha (0,t) + c \sigma' (s_o) = A + c \sigma' (s_o).$$

Similar computations as in (26) yield

$$J' (s_o) = \frac{d}{ds} \bigg|_{s_o} \frac{d}{dt} \bigg|_0 Y_{\cos (at)V_t + \sin (at)B_t} (s - s_o) = \alpha B_0 = \alpha A \times \sigma' (s_o).$$

In particular, $\|J' (s_o)\| = |\alpha|$. Therefore, if we show that $s_o = 0$, then both equations in (25) are true. We observe that $J (s_o) \perp J' (s_o)$. Since we know that $U \perp V$, using expression (23), we have that

$$0 = 2 \langle \cos_k (s_o) U (s_o) + \sin_k (s_o) V (s_o), -\kappa \sin_k (s_o) U (s_o) + \cos_k (s_o) V (s_o) \rangle$$

$$= (-\kappa \|u\|^2 + \|v\|^2) \sin_k (2s_o).$$

Now, we see that the first factor does not vanish and hence $s_o = 0$, as desired. Indeed, if it were zero, then $\|v\| = 0$ and so $J' (s_o) = -\kappa \sin_k (s_o) U (s_o)$. If $\kappa = 0$, this implies that $J' (s_o) = 0$. If $\kappa = -1$, then $\|u\| = \|v\| = 0$, and so $J' (s_o) = 0$ as well. In either case we have a contradiction, since $\|J' (s_o)\| = |\alpha| \neq 0$. □

Next we focus on the Euclidean case. Let $\phi : \mathbb{R}^2 \longrightarrow \mathbb{R}^3$, $\phi (s,t) = \beta (t) + s V (t)$ be a ruled parametrized surface with $\|V\| = 1$ which is nowhere cylindrical, that is, $V' (t) \neq 0$.
for all \( t \). It is said to be standard if \( \beta' \perp V' \). It is well-known that every nowhere cylindrical ruled surface admits such a parametrization; in this case \( \beta \) is called the striction line.

**Corollary 17** Let \( \alpha \neq 0 \), let \( \phi : \mathbb{R}^2 \rightarrow \mathbb{R}^3 \), \( \phi (s, t) = \beta (t) + sV (t) \), be a standard parametrized ruled surface and let \( \Gamma \) be the curve in \( \mathcal{G}_0 \) given by \( \Gamma (t) = [s \mapsto \phi (s, t)] \). Then \( \Gamma' (0) \) is \( \alpha \)-admissible if and only if

\[
\| V' (0) \| = |\alpha| \quad \text{and} \quad V' (0) = \alpha \beta' (0) \times V (0).
\]

**Proof** Let \( \sigma (s) = \phi (s, 0) \) and let \( J \) be the Jacobi field along \( \sigma \) associated with the variation \( \phi \), that is, \( J (s) = \beta' (0) + sV' (0) \). Since \( \phi \) is standard we have that \( J (0) = \beta' (0) \) is orthogonal to \( J' (0) = V' (0) \). Now, \( \Gamma' (0) = \mathcal{J}_0 (J) \), and so the assertion is an immediate consequence of the previous proposition in the Euclidean case. \( \square \)

In the next proposition we present the details of Example (c) after Proposition 6.

**Proposition 18** Given \( \alpha \neq 0 \), let \( \varphi \) be the ruled surface describing the circular helicoid with radius \( r \) and angular velocity \( \alpha \), that is, \( \varphi (s, t) = c (t) + sv (t) \) with

\[
c (t) = r \left( \cos \left( \frac{\ell}{r} \right) e_1 + \sin \left( \frac{\ell}{r} \right) e_2 \right) \quad \text{and} \quad v (t) = \cos (\alpha t) \frac{\ell}{r} c (t) + \sin (\alpha t) e_3,
\]

and let \( \Gamma (t) = [s \mapsto \varphi (s, t)] \) be the associated curve in \( \mathcal{G}_0 \). Then \( \Gamma' (0) \) is not \( \alpha \)-admissible.

**Proof** Since \( \varphi \) is nowhere cylindrical, it admits a standard parametrization \( \psi (s, t) = \beta (t) + sv (t) \) whose associated curve in \( \mathcal{G}_0 \) is \( \Gamma \). By the Lemma above, we have then that \( \| v' (0) \| = |\alpha| \) is a necessary condition for \( \Gamma' (0) \) to be \( \alpha \)-admissible. But \( \| v' (0) \|^2 = \| (1/r) e_2 + \alpha e_3 \|^2 = \alpha^2 + 1/r^2 \). Then, \( \Gamma' (0) \) is not \( \alpha \)-admissible. \( \square \)

Now we characterize the \( \alpha \)-admissible homogeneous curves in \( \mathcal{G}_0 \) that is, those which are orbits of monoparametric groups of rigid transformations. We exclude the trivial case \( \alpha = 0 \).

For \( s \in \mathbb{R} \), let \( R_s \) be the rotation through the angle \( s \) around the \( z \)-axis and \( T_s \) the translation given by \( T_s (x) = x + se_3 \).

**Proposition 19** a) Any homogeneous curve in \( \mathcal{G}_0 \) is congruent, via an orientation preserving isometry, to the orbit under the one parameter group \( t \mapsto R_{\theta t} T_{\lambda t} \) (for some \( \theta, \lambda \)) of the oriented line

\[
\ell = [s \mapsto \rho e_2 + s (\sin \eta \ e_1 + \cos \eta \ e_3)],
\]

for some \( \rho \geq 0 \) and \( \eta \).

b) Let \( \alpha \neq 0 \). Then the curve \( \Gamma \) in \( \mathcal{G}_0 \) given by \( \Gamma (t) = R_{\theta t} T_{\lambda t} \ell \) is \( \alpha \)-admissible if and only if

\[
|\theta \sin \eta| = |\alpha| \quad \text{and} \quad \alpha (\lambda + \rho \theta \cot \eta) = \theta.
\]

For instance, for \( \rho = 0, \eta = \pi/2, \theta = \alpha \) and \( \lambda = 1 \), we have that \( \Gamma = \Gamma_0^\alpha \) as in (11). Also, for \( \rho > 0, \lambda = 0 \) and \( \theta, \eta \) related by the equations, \( \Gamma \) is an \( \alpha \)-admissible curve sweeping a hyperboloid of one sheet.
Proof a) Let \( t \mapsto g_t \) be a monoparametric group of rigid transformations of \( \mathbb{R}^3 \). It is well known that there exist \( \theta, \lambda \) and \( h \in G_0 \) such that \( g_t = hR_{\theta t}T_{\lambda t}h^{-1} \) for all \( t \). Given \( \ell' \in G_0 \), we can find \( f \in G_0 \) commuting with \( R_{\theta t}T_{\lambda t} \) such that \( f^{-1}(h^{-1}\ell') \) is \( \ell' \) as in (28) for some \( \rho \geq 0, \eta \). Then, \( t \mapsto g_t \ell' = hR_{\theta t}T_{\lambda t}h^{-1} \ell' = hR_{\theta t}T_{\lambda t}f \ell = h f R_{\theta t}T_{\lambda t} \ell \), as desired.

b) We have that \( \Gamma (t) = [s \mapsto \phi (s, t)] \) with
\[
\phi (s, t) = R_{\theta t} (\rho e_2 + s (\sin \eta e_1 + \cos \eta e_3)) + t\lambda e_3 = \beta (t) + s V (t),
\]
where \( \beta (t) = \rho R_{\theta t} e_2 + t\lambda e_3 \) and \( V (t) = R_{\theta t} (\sin \eta e_1 + \cos \eta e_3) \). We may suppose that \( \theta \sin \eta \neq 0 \), since otherwise, on the one hand, equations (29) do not hold and on the other hand, the orbit of \( \ell \) sweeps either a plane or a cylinder and so it is not \( \alpha \)-admissible for \( \alpha \neq 0 \). Straightforward computations yield that \( \phi \) is a standard parametrized ruled surface, \( \beta ' (0) = \lambda e_3 - \rho \theta e_1 \) and \( V' (0) = \theta \sin \eta e_2 \).

In order to apply Corollary 17, we compute \( \| V' (0) \| = |\theta \sin \eta| \). Also, the equation \( \alpha \beta ' (0) \times V (0) = V' (0) \) translates into \( \alpha (\lambda e_3 - \rho \theta e_1) \times (\sin \eta e_1 + \cos \eta e_3) = \theta \sin \eta e_2 \), or equivalently,
\[
\alpha (\lambda \sin \eta + \rho \theta \cos \eta) e_2 = \theta \sin \eta e_2.
\]
Therefore, by the corollary, \( \Gamma' (0) \) is \( \alpha \)-admissible if and only if equations (29) hold. By the homogeneity of \( \Gamma \) and \( \mathcal{A}^0_\alpha \), this is equivalent to \( \Gamma' (t) \) being \( \alpha \)-admissible for all \( t \). \qed

3 Kendall’s Problem for Some Families of \( \alpha \)-Admissible Curves

This section addresses the analogue mentioned in the introduction of the well known rolling Kendall’s problem. Given a family \( \mathcal{F} \) of curves in a smooth manifold \( N \), the Kendall number of \( \mathcal{F} \) is the minimum number of pieces in \( \mathcal{F} \) of continuous curves in \( N \) taking an initial point to a final point in \( N \), both arbitrary and different.

We consider \( N = G_0 \) and two families of distinguished \( \alpha \)-admissible curves there: the family \( \mathcal{P}^\alpha \), consisting of all (pure) \( \alpha \)-helicoidal curves, that is, all curves \( \Gamma^\alpha_{\ell, p, A} \) as in Definition 3, and the family \( \mathcal{H}^\alpha \) of all the \( \alpha \)-admissible homogeneous curves in \( G_0 \). Note that this renders the result in Theorem 7 superfluous in the Euclidean case.

In the original Kendall’s problem of a sphere rolling on the plane without slipping and spinning, the most difficult case was to roll along successive straight lines from a given position to another one over the same point, but rotated through some angle. In our problem, the most complex case will be to reach \( -\ell \) from \( \ell \), two lines with the same image and opposite directions.

3.1 Kendall’s Problem for the Family \( \mathcal{P}^\alpha \)

Proposition 20 For \( \alpha \neq 0 \), the Kendall number of the family \( \mathcal{P}^\alpha \) is 3.

We begin by stating the following proposition, that implies that this number is greater than or equal to 3.

Proposition 21 Given \( \alpha \neq 0 \), the oriented straight lines \( \ell \) and \( -\ell \) cannot be connected by a continuous curve of two \( \alpha \)-helicoidal pieces.
**Proof** Without loss of generality, we may suppose that \( \ell = [s \mapsto se_1] \) (so, \(-\ell = [s \mapsto -se_1] \)) and that the first piece is \( \Gamma_{\ell,0,e_2} \), defined on the interval \([0, t_0] \). We call \( \ell_1 = \Gamma_{\ell,0,e_2} (t_0) \neq -\ell \).

We denote by \( v \) the direction of \( \ell_1 \), which is orthogonal to \( e_2 \) (the direction of the axis of the first piece), so we can write \( v = x e_1 + z e_3 \) with \( x^2 + z^2 = 1 \).

Now we assume that there exist \( p \in \ell_1 \), a unit vector \( A \) orthogonal to \( \ell_1 \) and \( t_1 \) such that \( \Gamma_{\ell_1,p,A}(t_1) = -\ell \). Since the axis of \( \Gamma_{\ell_1,p,A} \) is orthogonal to \(-\ell \) and \( \ell_1 \), we have that \( \langle A, e_1 \rangle = 0 = \langle A, v \rangle \). Hence \( z \langle A, e_3 \rangle = 0 \).

If \( z = 0 \), then \( v = \pm e_1 \) and so \( p = t_0 e_2 + s_0 e_1 \) for some \( s_0 \). Since the axis \( t \mapsto p + t A \) of \( \Gamma_{\ell_1,p,A} \) intersects \(-\ell \) at \( t_1 \), we have that \( p + t_1 A = s'_0 e_1 \) for some \( s'_0 \). Now, \( s_o = \langle t_0 e_2 + s_0 e_1, e_1 \rangle = \langle -t_1 A + s'_0 e_1, e_1 \rangle = s'_0 \).

Then there exists \( \varepsilon = \pm 1 \) such that \( A = \varepsilon e_2 \) and \( t_1 = -\varepsilon t_0 \) and thus \( \Gamma_{\ell_1,p,A} \) travels the same path as \( \Gamma_{\ell,0,e_1,e_2} \) if \( \varepsilon = 1 \) or backwards if \( \varepsilon = -1 \). Therefore, \( \Gamma_{\ell_1,p,A}(t_1) = \ell \neq -\ell \). If \( \langle A, e_3 \rangle = 0 \), then \( A = \pm e_2 \), a situation we have already considered. \( \square \)

**Proof of Proposition 20** We know from the previous proposition that the Kendall number of \( \mathcal{H}^\alpha \) is greater than or equal to 3. Given \( \ell \) and \( \ell' \) in \( \mathcal{H}_0 \), we want to achieve \( \ell' \) from \( \ell \) via the juxtaposition of three \( \alpha \)-helicoidal curves in \( \mathcal{H}_0 \). Without loss of generality we may assume that \( \ell' = [s \mapsto se_1] \) and \( \ell = [s \mapsto de_2 + sv] \) for some \( d \geq 0 \) and some unit vector \( v \) orthogonal to \( e_2 \). We consider first the case \( \alpha > 0 \).

Let \( \Gamma_1 = \Gamma_{\ell_1,e_2,e_2}^\alpha \), that is, the \( \alpha \)-helicoidal curve with initial ray \( \ell \) and axis paring from \( de_2 \) with direction \( e_2 \). Let \( y_1(t) = e_2 \) be the point where \( \Gamma_1 \) intersects the \( y \)-axis. Let \( t_1 > 0 \) be such that the direction of \( \ell_1 = \text{def} \Gamma_1(t_1) \) is \(-e_3 \) and \( y_1(t_1) > \frac{\pi}{2\alpha} \). See Fig. 3

Let \( \Gamma_2 = \Gamma_{\ell_1,p_1,e_1}^\alpha \) where \( p_1 = y_1(t_1) e_2 \). For each \( t \) we consider the distance \( f(t) \) between \( \Gamma_2(t) \) and \( \ell' \). We have that \( f(0) = y_1(t_1) \). By the continuity of \( f \), if \( \tau \) is the first positive zero of \( f \), there exists \( 0 \leq t_2 < \tau \) such that \( f(t_2) = \frac{\pi}{2\alpha} \).

Call \( \ell_2 = \Gamma_2(t_2) \) and let \( p_2 \) and \( p_3 \) be the points in \( \ell_2 \) and \( \ell' \), respectively, realizing the distance between these lines. Let \( A = \frac{p_3 - p_2}{\|p_3 - p_2\|} \) and \( \Gamma_3 = \Gamma_{\ell_2,e_2}^\alpha \). Then \( \Gamma_3 \left( \frac{\pi}{2\alpha} \right) = \ell' \), since \( \pi \) is the time an \( \alpha \)-helicoidal curve takes to make one fourth of a complete turn. See Fig. 4.

If \( \alpha < 0 \), similar arguments hold, setting the direction of \( \ell_1 \) equal to \( e_3 \) and substituting \( \frac{\pi}{2\alpha} \) with \( \frac{\pi}{2|\alpha|} \). \( \square \)
3.2 Kendall’s Problem for the Family $\mathcal{H}^\alpha$

The elements of the family $\mathcal{H}^\alpha$ of all $\alpha$-admissible homogeneous curves in $\mathbb{G}_0$ for $\alpha \neq 0$ have been described in Proposition 19.

**Proposition 22** Let $\alpha \neq 0$. The Kendall number of the family $\mathcal{H}^\alpha$ is 2.

**Proof** First of all, we check that two intersecting lines $\ell$ and $\ell'$, with $\ell' \neq \pm \ell$, can be joined by one curve in $\mathcal{H}^\alpha$. If they form an angle $0 < 2\eta < \pi$, we may suppose without loss of generality that $\ell = [s \mapsto (\sin \eta, 0, \cos \eta)]$ and $\ell' = [s \mapsto (0, 0, \frac{\pi}{\alpha}) + s (0, 0, -\sin \eta, 0, \cos \eta)]$.

Let $\Gamma$ be the curve in $\mathbb{G}_0$ determined by the orbit of $\ell$ under the monoparametric group $h_t = R_{\theta t} T_{\lambda t}$ as in Proposition 19, with $\theta = \frac{\alpha}{\sin \eta}$ and $\lambda = \frac{1}{\sin \eta} (\rho = 0)$. The curve is $\alpha$-admissible since the corresponding equations given in (29) are satisfied. One can also verify easily that $\Gamma \left( \frac{\pi}{\theta} \right) = \ell'$. Thus, $\ell$ and $\ell'$ can be joined by one $\alpha$-admissible homogeneous curve. See Fig. 5.

Now we consider two lines $\ell$ and $\ell'$ in $\mathbb{G}_0$ that do not intersect. Let $\ell_1 \in \mathbb{G}_0$ containing the shortest segment joining $\ell$ to $\ell'$, which is perpendicular to both of them. By the case above with $2\eta = \frac{\pi}{2}$, $\ell'$ can be reached from $\ell$ via the juxtaposition of two curves in $\mathcal{H}^\alpha$, the first joining $\ell$ to $\ell_1$ and the second joining $\ell_1$ to $\ell'$. If $\ell' = -\ell$, one can take as $\ell_1$ any curve orthogonal to $\ell$. Then, the Kendall number is at most 2.

Finally, we show that the Kendall number is greater than 1. It suffices to see that for the monoparametric group $t \mapsto g_t = R_{\theta t} T_{\lambda t}$ as in Proposition 19, if $t \mapsto g_t (\ell)$ is $\alpha$-admissible for some $\ell \in \mathbb{G}_0$, then $g_t (\ell) \neq -\ell$ for all $t$. We may suppose that $\ell = [s \mapsto \rho e_2 + sv]$ is as in (28). The direction of $g_t (\ell)$ is $R_t (v)$. If $g_t (\ell) = -\ell$, then $R_t (v) = -v$ and equating the third components yields $\cos \eta = -\cos \eta$ and so $\cos \eta = 0$. In particular, $\ell$ is contained in the plane $z = 0$. Now, equations (29) imply that

$$|\theta| = |\alpha| \quad \text{and} \quad \alpha \lambda = \theta.$$ 

Hence, $g_t = R_{\lambda t} T_{\lambda t}$ with $\lambda = \pm 1$. Since $g_t \ell$ is contained in the plane $z = \lambda t$, we have that $g_t \ell \neq -\ell$ for all $t$ (otherwise, we get $\lambda = 0$, a contradiction). \hfill $\square$
