Abstract. We introduce a generic expression language describing behaviours of finite coalgebras over sets; besides relational systems, this covers, e.g., weighted, probabilistic, and neighbourhood-based system types. We prove a generic Kleene-type theorem establishing a correspondence between our expressions and finite systems. Our expression language is similar to one introduced in previous work by Myers but has a semantics defined in terms of a particular form of predicate liftings as used in coalgebraic modal logic; in fact, our expressions can be regarded as a particular type of modal fixed point formulas. The predicate liftings in question are required to satisfy a natural preservation property; we show that this property holds in particular for the Moss liftings introduced by Marti and Venema in work on lax extensions.

1 Introduction

Expression languages that support the syntactic description of system behaviour are one of the classical topics in computer science. The prototypic example are regular expressions; further examples include Kleene algebra with tests [17] and expression languages for labelled transition systems [1].

There has been recent interest in phrasing such expression languages generically, obtaining their syntax and semantics as well as meta-theoretic results including Kleene theorems by instantiation of a parametrized framework. This is achieved by abstracting the type of systems as coalgebras for a given type functor. This line of work originates with expression languages for a specific class of functors that essentially covers relational systems, so-called Kripke polynomial functors [34], and was subsequently extended to cover also weighted systems [32].

A generic expression language for arbitrary finitary functors can be based on algebraic functor presentations [25]. Here, we introduce a similar and, as it will turn out, in fact largely equivalent generic expression language for finitary functors, which we base on coalgebraic modalities in predicate lifting style, following the paradigm of coalgebraic logic [9]; on predicate liftings, we impose strong conditions, notably including preservation of singletons. Martí and Venema [20] have shown that for functors admitting a lax extension (in particular for functors

* Work forms part of the DFG project COAX (MI 717/5-1 / SCHR 1118/11-1)
that admit a separating set of monotone predicate liftings), one can convert operations from the functor presentation into predicate liftings, the so-called **Moss liftings**. We show that the Moss liftings preserve singletons; the converse does not hold in general, i.e. not all singleton-preserving predicate liftings are Moss liftings under a given lax extension.

We thus arrive at a generic expression language that covers, e.g., various flavours of relational, weighted, and probabilistic systems, as well as monotone neighbourhood systems as in the semantics of game logic [26] and concurrent dynamic logic [29]. We prove a Kleene theorem stating that every expression denotes the behavioural equivalence class of some state in a finite system, and that conversely every such behavioural equivalence class is denoted by some expression.

We make no claim to novelty for the design of a generic expression language as such, and in fact the expression language developed by Myers in his PhD dissertation [25] appears to be even more general. In particular, unlike Myers’ language our expression language is currently restricted to describing behavioural equivalence classes in set-based coalgebras, and does not yet support algebraic operations (e.g. a join semilattice structure as in Silva et al.’s language for Kripke-polynomial functors [34] or in fact in standard regular expressions). The main point we are making is, in fact, a different one: we show that

\[ \text{coalgebraic expression languages embed into coalgebraic logic,} \]

specifically into (the conjunctive fragment of) the coalgebraic \( \mu \)-calculus [8], extending the classical result that every bisimilarity class of states in finite labelled transition systems is expressible by a *characteristic formula* in the \( \mu \)-calculus [14,10,35,2]. This result provides a direct link between descriptions of processes and their property-oriented specification; as indicated above, the key to lifting it to a coalgebraic level of generality are singleton-preserving predicate liftings.

**Related Work** As mentioned above, we owe much to work by Marti and Venema on Moss liftings [20], and moreover we use a notion of \( \Lambda \)-bisimulation [12] that turns out to be an instance of their definition of bisimulation via lax extensions. Besides the mentioned work on generic expression languages for Kripke polynomial [34], weighted [32], and finitary [25] functors, there is work on expression languages for reactive \( T \)-automata [11], which introduce an orthogonal dimension of genericity: The coalgebra functor as such remains fixed but the computational capacities of the automaton model at hand are encapsulated as a computational monad [23]. Venema [38] proves that for weak-pullback preserving functors, every bisimilarity class of finite coalgebras is expressible in coalgebraic fixpoint logic over Moss’ \( \nabla \) modality.

## 2 Preliminaries

In the standard paradigm of universal coalgebra, types of state-based systems are encapsulated as endofunctors. We recall details on presentations of set functors
and on their property-oriented description via predicate-lifting based coalgebraic modalities.

**Functor Presentations** describe set functors by signatures of operations and a certain restricted form of equations, so-called flat equations, alternatively by a suitable natural surjection. A signature is a sequence \( \Sigma = (\Sigma_n)_{n \in \omega} \) of sets. Elements of \( \Sigma_n \) are regarded as \( n \)-ary operation symbols (we write \( \tau/n \in \Sigma \) for \( \tau \in \Sigma_n \)). Every signature \( \Sigma \) determines the corresponding polynomial endofunctor \( T_\Sigma \) on \( \text{Set} \), which maps a set \( X \) to the set

\[
T_\Sigma X = \prod_{n \in \omega} \Sigma_n \times X^n
\]

and similarly on maps.

**Definition 2.1.** A presentation of a functor \( T : \text{Set} \to \text{Set} \) is a pair \((\Sigma, \alpha)\) consisting of a signature \( \Sigma \) and a natural transformation \( \alpha : T_\Sigma \Rightarrow T \) with surjective components \( \alpha_X \). In the following, we abuse notation and denote, for every \( \tau/n \in \Sigma \), the corresponding coproduct component of \( \alpha : T_\Sigma \Rightarrow T \) again by \( \tau : (\_)^n \to T \), and refer to it as an operation of \( T \).

Most of our results concern finitary set functors. Recall that a functor is finitary if it preserves filtered colimits. Over \( \text{Set} \), we have the following equivalent characterizations:

**Theorem 2.2 (Adámek and Trnkova [3]).** Let \( T : \text{Set} \to \text{Set} \) be a functor. Then the following are equivalent:

1. \( T \) is finitary;
2. \( T \) is bounded, i.e. for every element \( x \in TX \) there exists a finite subset \( m : Y \rightharpoonup X \) and an element \( y \in TY \) such that \( x = Tm(y) \);
3. \( T \) has a presentation.

Indeed, for the equivalence of (1) and (3) note that every polynomial functor \( T_\Sigma \) is finitary, and finitary functors are closed under taking quotient functors. Conversely, given a finitary functor \( T \), let \( \Sigma_n = Tn \) and define \( \alpha_X : T_\Sigma X \to TX \) by \( \alpha_X(\tau, t) = Tt(\tau) \), where \( t \in X^n \) is considered as a function \( n \to X \). It is easy to show that this yields a natural transformation with surjective components.

**Remark 2.3.** As indicated above, the natural surjection \( \alpha \) in a functor presentation \((\Sigma, \alpha)\) can be replaced with a set of flat equations over \( \Sigma \), where an equation is called flat if both sides consist of an operation symbol applied to variables [3]. Incidentally, this (standard) term should not be confused with the same term introduced in the context of our expression language in Section 5.

**Example 2.4.** (1) Let \( A \) be an input alphabet. The functor \( TX = 2 \times X^A \), whose coalgebras are deterministic automata, is polynomial, and finitary if \( A \) is finite. Thus, \( T \) has a presentation \((\Sigma, \alpha)\) by a signature \( \Sigma \) with two \(|A|\)-ary operations and no equations, i.e. \( \alpha \) is the natural isomorphism \( T_\Sigma \cong 2 \times (\_)^A \).
To begin, \( \tau \) minimal elements, all of them finite, such that every element of \( \tau \) is generated on objects by \( n \) each \( D \) to \( p \) formal convex combinations \( \{ \text{functor} \ R \} \). The presentation \( \Sigma,\alpha \) as for \( \mathcal{X} \), we obtain a presentation \( \mathcal{X} \). Concretely, \( \mathcal{B} \) maps a set \( X \) to the set \( \mathcal{B} \mathcal{X} \) of bags (i.e. finite multisets) on \( X \). Since \( (\mathbb{N},+,0) \) is generated by \( G = \{1\} \), we have the same signature as for \( \mathcal{P} \), namely one \( n \)-ary operation symbol per \( n \in \omega \); of course, the presentation \( \alpha \) now identifies fewer tuples, e.g. distinguishes \((x_1,x_2,x_1)\) and \((x_1,x_2)\).

(2) For a commutative monoid \( (M,+,0_M) \) the monoid-valued functor \( M(-) : \textbf{Set} \to \textbf{Set} \) is defined by
\[
M^X = \{ \mu : X \to M \mid \mu(x) = 0_M \text{ for all but finitely many } x \in X \}
\]
and by \( M^{(b)}(\mu) = y \mapsto \sum_{h(x) = y} \mu(x) \) on maps \( h : X \to Y \). We view elements of \( M^{(X)} \) as finitely supported additive measures on \( X \), and in particular write \( \mu(A) = \sum_{x \in A} \mu(x) \) for \( A \subseteq X \); in this view, maps \( M^{(b)} \) just take image measures. For a set \( G \subseteq M \) of generators (i.e. there exists a surjective monoid morphism \( G^\ast \to M \)), \( M(-) \) is represented by
\[
\alpha_X : \prod_{n \in \omega} G^n \times X^n \to M^{(X)}, \quad \alpha_X(\tau, t) = M^X(\tau),
\]
where \( \tau \in G^n \) is considered as an element of \( M^{(n)} \).

(3) The finite powerset functor \( \mathcal{P} \) (with \( \mathcal{P}_\omega(X) \) being the set of finite subsets of \( X \)) is the monoid-valued functor for the monoid \((\{0,1\},\lor,0)\). Since this is generated by \( G = \{1\} \), we have one \( n \)-ary operation symbol for each \( n \in \omega \):
\[
\alpha_X : \prod_{n \in \omega} X^n \to \mathcal{P}_\omega X, \quad \alpha_X(x_1,\ldots,x_n) = \{x_1,\ldots,x_n\};
\]
e.g. \( \alpha \) identifies the tuples \((x_1,x_1,x_2)\) and \((x_1,x_2)\).

(4) For the monoid \( \mathbb{N} \) of natural numbers with addition, one obtains the bag functor \( \mathcal{B} \) as \( \mathbb{N}(-) \). Concretely, \( \mathcal{B} \) maps a set \( X \) to the set \( \mathcal{B} \mathcal{X} \) of bags (i.e. finite multisets) on \( X \). Since \( (\mathbb{N},+,0) \) is generated by \( G = \{1\} \), we have the same signature as for \( \mathcal{P} \), namely one \( n \)-ary operation symbol per \( n \in \omega \); of course, the presentation \( \alpha \) now identifies fewer tuples, e.g. distinguishes \((x_1,x_2,x_1)\) and \((x_1,x_2)\).

(5) The \emph{finite distribution functor} \( \mathcal{D} \) is a subfunctor of the monoid-valued functor \( \mathbb{R}^{(-)} \) for the additive monoid of the non-negative reals, given by \( \mathcal{D} \mathcal{X} = \{ \mu \in \mathbb{R}^{(-)}_\geq 0 \mid \sum_{x \in X} \mu(x) = 1 \} \). Note that elements of \( \mathcal{D} \mathcal{X} \) can be represented as formal convex combinations \( \sum_{i=1}^n p_i x_i \), \( p_i \in \mathbb{R}_{\geq 0}, x_i \in X \) for \( i = 1,\ldots,n \), with \( p_1 + \cdots + p_n = 1 \). Taking \( \mathbb{R}_{\geq 0} \) itself as the set of generators and restricting to \( \mathcal{D} \), we obtain a presentation \((\Sigma,\alpha)\) with an \( n \)-ary operation symbol for each \( n \)-tuple \((p_1,\ldots,p_n) \in \mathbb{R}^n_\geq 0 \) such that \( p_1 + \cdots + p_n = 1 \), and \( \alpha_X \) maps \((p_1,\ldots,p_n),(x_1,\ldots,x_n)\) to the formal convex combination \( \sum_{i=1}^n p_i x_i \).

(6) The \emph{finitary monotone neighbourhood functor} \( \mathcal{M}_\omega \), i.e. the finitary part of the standard monotone neighbourhood functor \( \mathcal{M} \), can be described as follows. To begin, \( \mathcal{M} \) is the subfunctor of the double contravariant powerset functor \( \mathcal{Q} \mathcal{Q}^{op} \) given on objects by
\[
\mathcal{M} \mathcal{X} = \{ \mathfrak{A} \subseteq \mathcal{Q}(X) \mid \mathfrak{A} \text{ upwards closed under } \subseteq \}.
\]
We can then describe \( \mathcal{M}_\omega \mathcal{X} \) as consisting of all \( \mathfrak{A} \in \mathcal{M} \mathcal{X} \) having finitely many minimal elements, all of them finite, such that every element of \( \mathfrak{A} \) is above
a minimal one. We have the following presentation of $\mathcal{M}_\omega$: For every choice of numbers $n \geq 0$, $k_1,\ldots,k_n \geq 0$, we have a $\sum_{i=1}^{n} k_i$-ary operation mapping $(x_{ij})_{i=1,\ldots,n;j=1,\ldots,k_i}$ to the upwards closure of the set system

$$\{\{x_{i1},\ldots,x_{ik_i}\} \mid i = 1,\ldots,n\}.$$  

**Coalgebraic Logic** Since coalgebras serve as generic models of reactive systems, it is natural to specify properties of coalgebras in terms of suitable modalities. The semantics of coalgebraic modalities can be defined using *predicate liftings* [27,30], which specify how a predicate on a base set $X$ induces a predicate on the set $TX$ where $T$ is the coalgebraic type functor:

**Definition 2.5.** For $n \in \omega$ an $n$-ary predicate lifting for a functor $T : \text{Set} \to \text{Set}$ is a natural transformation $\lambda : Q^n \to QT^{\text{op}}$ where $Q : \text{Set}^{\text{op}} \to \text{Set}$ is the contravariant powerset functor, with $Qf$ taking preimages, i.e.

$$Qf(A) = f^{-1}[A].$$

We write $\lambda/n$ to indicate that $\lambda$ has arity $n$. A predicate lifting $\lambda$ is *monotone* if it preserves set inclusion in every argument. A set $\Lambda$ of predicate liftings is *separating* [28,30] if every $t \in TX$ is uniquely determined by the set $T_\lambda(t) = \{(\lambda, A_1,\ldots,A_n) \mid \lambda/n \in \Lambda, A_i \in QX \text{ and } t \in \lambda X(A_1,\ldots,A_n)\}$.

**Example 2.6.** The basic example is the interpretation of the standard box modality $\Box$ over the covariant powerset functor $P$ (with $ Pf$ taking direct images), given by the monotone unary predicate lifting $\lambda$ defined by

$$\lambda_X(A) = \{B \in P(X) \mid B \subseteq A\}.$$  

For a further monotone example, we interpret the box modality over the monotone neighbourhood functor $M$ (Example 2.4) by the monotone unary predicate lifting

$$\lambda_X(A) = \{A \in MX \mid A \subseteq A\}.$$  

It is easy to see that in both these examples, the predicate lifting for $\Box$ alone is separating.

 Predicate-lifting-based modalities can be embedded into *coalgebraic logics* of varying degrees of expressiveness. Our expression language introduced in Section 5 will live inside the *coalgebraic $\mu$-calculus* [8], more precisely its *conjunctive fragment* [13]. We defer details to Section 5.
3 Singleton-Preserving Predicate Liftings

Our generic expression language will depend on a specific type of predicate liftings, as well as on a strengthening of separation:

Definition 3.1. An \( n \)-ary predicate lifting \( \lambda \) preserves singletons if

\[
|\lambda_X(\{x_1\}, \ldots, \{x_n\})| = 1
\]

for all \( x_1, \ldots, x_n \in X \). Moreover, a set \( \Lambda \) of predicate liftings is strongly expressive if for every \( t \in TX \) there exist \( \lambda/n \in \Lambda \) and \( x_1, \ldots, x_n \in X \) such that

\[
\{t\} = \lambda_X(\{x_1\}, \ldots, \{x_n\}).
\]

Singleton preservation will serve to ensure that expressions of our language denote unique behaviours, while strong expressivity will guarantee that all (finite) behaviours are expressible. The following is immediate:

Lemma 3.2. Every strongly expressive set of predicate liftings is separating.

Example 3.3. The predicate liftings in Example 2.6 both fail to preserve singletons. Our main source of singleton-preserving predicate liftings are Moss liftings as introduced in general terms in the next section. For the finite powerset functor \( P_\omega \) consider the predicate liftings

\[
\lambda^n_X(\pi_1^{-1}(\{\top\}), \ldots, \pi_n^{-1}(\{\top\})) \subseteq T(2^n),
\]

and \( C \subseteq T(2^n) \) to the lifting \( \lambda \) defined by

\[
\lambda_X(A_1, \ldots, A_n) = \{ t \in TX \mid T(\chi_{A_1} \otimes \cdots \otimes \chi_{A_n})(t) \in C \},
\]

where \( \pi_i : 2^n \to 2 \) is the \( i \)-th projection and \( \chi_A : X \to 2 \) denotes the characteristic function of \( A \subseteq X \).

An \( n \)-ary predicate lifting is a singleton lifting if it corresponds to a singleton subset of \( T(2^n) \).

Remark 3.4. Singleton-preserving predicate liftings should not be confused with Kurz and Leal’s singleton liftings [19,18]. The definition of the latter is based on the one-to-one correspondence between subsets of \( T(2^n) \) and \( n \)-ary predicate liftings for \( T \) [30], which maps an \( n \)-ary predicate lifting \( \lambda \) to \( \lambda^n_2(\pi_1^{-1}(\{\top\}), \ldots, \pi_n^{-1}(\{\top\})) \subseteq T(2^n) \), and \( C \subseteq T(2^n) \) to the lifting \( \lambda \) defined by

\[
\lambda_X(A_1, \ldots, A_n) = \{ t \in TX \mid T(\chi_{A_1} \otimes \cdots \otimes \chi_{A_n})(t) \in C \},
\]

where \( \pi_i : 2^n \to 2 \) is the \( i \)-th projection and \( \chi_A : X \to 2 \) denotes the characteristic function of \( A \subseteq X \).

An \( n \)-ary predicate lifting is a singleton lifting if it corresponds to a singleton subset of \( T(2^n) \).

It is then indeed immediate that every unary singleton-preserving predicate lifting \( \lambda \) is a singleton lifting, since the above correspondence maps \( \lambda \) to the singleton \( \lambda_2(\{\top\}) \). The following examples show that this implication breaks down at higher arities, and that the converse also fails in general.

Example 3.5. (1) The unary singleton lifting for \( P \) corresponding to \( \{\{\top\}\} \subseteq P2 \) fails to preserve singletons. Of course, this lifting fails to be monotone.
(2) Binary monotone singleton liftings need not preserve singletons. E.g. for the distribution functor $\mathcal{D}$, the monotone singleton lifting $\lambda$ corresponding to $\{1 \cdot (\top, \top)\} \subseteq \mathcal{D}(2^2)$ is given by $\lambda(A, B) = \{\mu \mid \mu(A) = \mu(B) = 1\}$, so $\lambda(\{x\}, \{y\}) = \emptyset$ for $x \neq y$. We leave it as an open question whether unary monotone singleton liftings preserve singletons.

(3) The binary singleton-preserving predicate lifting $\lambda(A, B) = \{\mu \mid \mu(A) \geq 1/2, \mu(B) \geq 1/2, \mu(A \cup B) = 1\}$ for the distribution functor $\mathcal{D}$ (see Example 4.7 for details) is not a singleton lifting, as it corresponds to the following infinite subset of $\mathcal{D}(2^2)$:

$\{\mu \mid \mu(2 \times \{\top\}) \geq 1/2, \mu(\{\top\} \times 2) \geq 1/2, \mu(2 \times \{\top\} \cup \{\top\} \times 2) = 1\}$.

It is not hard to see that we can recover operations for a functor from monotone singleton preserving predicate liftings; in detail:

**Lemma 3.6.** Let $T : \textbf{Set} \to \textbf{Set}$. Then the following hold.

1. For each monotone singleton-preserving predicate lifting $\lambda/n$, 
   \[\{\tau\lambda,X(x_1, \ldots, x_n) \coloneqq \lambda_X(\{x_1\}, \ldots, \{x_n\}\} \quad (3.2)\]
   defines a natural transformation $\tau\lambda : (-)^n \to T$.

2. If $\Lambda$ is a strongly expressive set of monotone singleton-preserving predicate liftings, then taking operation symbols $\tau\lambda$ for each $\lambda \in \Lambda$, with associated interpretation as per (3.2), yields a functor presentation of $T$.

**Example 3.7.** The singleton-preserving predicate liftings $\lambda^n$ from Example 2.6 induce, according to the above construction, the operations $X^n \to P_\omega(X)$, $(x_1, \ldots, x_n) \mapsto \{x_1, \ldots, x_n\}$.

The other direction, generating predicate liftings from functor presentations, is more involved, and treated next.

### 4 Moss Liftings

Marti and Venema [20] introduce Moss liftings, predicate liftings that are constructed from functor presentations with the help of a generalized form of the nabla operator, extending an earlier construction for weak-pullback preserving functors by Kurz and Leal [18]. Recall that for a weak-pullback-preserving functor $T$, Moss’ [24] classical nabla operator $\nabla : T\mathcal{Q} \Rightarrow QT^{\text{op}}$ is the natural transformation defined by

$\nabla(\Phi) = \{t \in TX \mid (t, \Phi) \in T(\in_X)\}$.

Here, $\in_X \subseteq X \times QX$ is the element-of relation for $X$, and $T$ is the Barr extension of $T$, viz. the functor $T$ on the category of sets and relations defined on a relation
$R \subseteq X \times Y$ by $\overline{T}R = \{(T\pi_1(r), T\pi_2(r)) \mid r \in TR\}$, where $\pi_1 : R \rightarrow X$ and $\pi_2 : R \rightarrow Y$ are the projection maps (cf. [24]). Barr [5] (see also Trnková [37]) proved that $\overline{T}$ is a functor if and only if $T$ preserves weak pullbacks.

Further recall that the converse of a relation $R \subseteq X \times Y$ is the relation $R^\circ = \{(y, x) \mid x R y\} \subseteq Y \times X$. We denote the composite of two relations $R \subseteq X \times Y$ and $S \subseteq Y \times Z$ diagrammatically by $R; S \subseteq X \times Z$. Also, for $A \subseteq X$ we denote by $R[A] = \{y \mid \exists x \in A. x R y\}$.

The construction $T \mapsto \overline{T}$ is generalized and abstracted in the notions of relation lifting and, more specifically, lax extension of a functor, as recalled next.

**Definition 4.1 (Relation lifting, lax extension [20]).** A relation lifting $L$ for a functor $T$ is an assignment mapping every relation $R \subseteq X \times Y$ to a relation $LR \subseteq TX \times TY$ such that converses are preserved: $L(S^\circ) = (LS)^\circ$. A relation lifting $L$ is a lax extension if for all relations $R, R' \subseteq X \times Z$, $S \subseteq Z \times Y$ and functions $f : X \rightarrow Z$ (identified with their graph relation) the following hold:

$$R' \subseteq R \Rightarrow LR' \subseteq LR,$$
$$LR; LS \subseteq L(R; S),$$
$$Tf \subseteq Lf.$$

A lax extension $L$ preserves diagonals if for all sets $X$

$$L\Delta_X \subseteq \Delta_{TX}.$$

**Proposition 4.2 (Properties of Lax Extensions [20]).** Let $L$ be a lax extension for a functor $T$. Then for all functions $f : X \rightarrow Z$, $g : Y \rightarrow Z$ and relations $R \subseteq X \times Z$, $S \subseteq Z \times Y$,

i) $\Delta_{TX} \subseteq L\Delta_X$,

ii) $Tf; LS = L(f; S)$ and $LR; (Tg)^\circ = L(R; g^\circ)$,

and if $L$ preserves diagonals, then

iii) $\Delta_{TX} = L\Delta_X$ and $Tf = Lf$,

iv) $Tf; (Tg)^\circ = L(f; g^\circ)$.

One use of relation liftings is to determine coalgebraic notions of bisimulation:

**Definition 4.3 (L-Bisimulation [20]).** Let $L$ be a relation lifting for a functor $T : \text{Set} \rightarrow \text{Set}$, and let $(X, \xi)$, $(Y, \zeta)$ be $T$-coalgebras. A relation $S \subseteq X \times Y$ is an $L$-simulation if for all $x \in X$ and $y \in Y$,

$$x Sy \text{ implies } \xi(x) LS \zeta(y).$$

An $L$-bisimulation is a relation $S$ such that $S$ and $S^\circ$ are $L$-simulations. Two states are $L$-bisimilar if there exists an $L$-bisimulation relating them.

Marti and Venema [20, Theorem 11] show that if $L$ is a lax extension that preserves diagonals, then $L$-bisimilarity coincides with behavioural equivalence.
Assumption 4.4. From now on we fix a finitary endofunctor $T : \text{Set} \to \text{Set}$ having a diagonal-preserving lax extension $L$ and a presentation $(\Sigma, \alpha)$ of $T$.

Another key feature of lax extensions is that they induce canonical modalities, generalizing Moss’ coalgebraic logic [24]:

Definition 4.5 (Lax Nabla [20]). The lax nabla of $L$ is the family of functions

$$\nabla^L : TQX \to QT^{\text{op}}X$$

$$\Phi \mapsto \{t \in TX \mid (t, \Phi) \in L(\in_X)\},$$

where $\in_X \subseteq X \times QX$ is the element-of relation for $X$.

As shown by Marti and Venema [20], the lax nabla is in fact a natural transformation $\nabla^L : TQ \Rightarrow QT^{\text{op}}$, and coincides with Moss’ classical $\nabla$ for $L$ being the Barr extension of $T$ (and $T$ preserving weak pullbacks). In combination with a functor presentation, the lax nabla gives rise to a family of predicate liftings:

Definition 4.6 (Moss Liftings [20]). Every operation symbol $\tau/n \in \Sigma$ yields a predicate lifting $\lambda$ defined by

$$\lambda = (Q^n \xrightarrow{\tau^n} TQ \xrightarrow{\nabla^L} QT^{\text{op}}),$$

that is,

$$\lambda_X(X_1, \ldots, X_n) = \{t \in TX \mid (t, \tau_X(X_1, \ldots, X_n)) \in L(\in_X)\}.$$

These predicate liftings are called the Moss liftings of $T$.

Example 4.7. Some standard functor presentations are converted into Moss liftings as follows.

1. For the deterministic automata functor $TX = 2 \times X^A$ consider the Barr extension $L = T$. Then elements of $TQX$ are pairs $(b, (Y_a)_{a \in A})$, where each $Y_a$ is a subset of $X$, and

$$\nabla(X, (Y_a)_{a \in A}) = \{(b, (x_a)_{a \in A}) \mid \forall a \in A : x_a \in Y_a\} \quad \text{for } b = 0, 1.$$

The two Moss liftings $\lambda^0, \lambda^1 : Q^A \to Q(2 \times (-)^A)$ corresponding to the two $|A|$-ary operation symbols from the presentation in Example 2.4.1 are thus defined (slightly abusing notation) by

$$\lambda^0((Y_a)_{a \in A}) = \{(i, (x_a)_{a \in A}) \mid \forall a \in A : x_a \in Y_a\} \quad \text{for } i = 0, 1.$$

2. As indicated in Example 2.4, the finite powerset functor $P_\omega$ has operations $\tau^n/n$ given by $\tau^n(x_1, \ldots, x_n) = \{x_1, \ldots, x_n\}$. The Moss lifting $\lambda^n$ associated to $\tau^n$ when using the Barr extension is exactly the one given by (3.1) above.
(3) Recall from Example 2.4 that the operations of the finite distribution functor $\mathcal{D}$ take formal convex combinations. Via the Barr extension, such an operation, determined by coefficients $p_1, \ldots, p_n$ such that $\sum p_i = 1$, induces the predicate lifting $\lambda$ given by $\lambda_X(A_1, \ldots, A_n)$ consisting of all $\mu \in \mathcal{D}X$ such that there exists a distribution on $e_X$ (a subset of $X \times Q(X)$) whose marginal distributions are $\mu$ (on $X$) and the distribution $\nu$ on $Q(X)$ given by $\nu([A_i]) = p_i$, respectively. In fact, however, this description can be substantially simplified; e.g. one readily checks that in the case $n = 2$, we actually have

$$\lambda(A_1, A_2) = \{ \mu \in \mathcal{D}(X) \mid \mu(A_1) \geq p_1, \mu(A_2) \geq p_2, \mu(A_1 \cup A_2) = 1 \}.$$ 

(The generalization to higher arities is via what is nowadays known as the splitting lemma [36, Theorem 11].)

(4) For the finitary monotone neighbourhood functor $\mathcal{M}_\omega$ (Example 2.4), we obtain Moss liftings as follows. Marti and Venema [20] define a diagonal-preserving singletons:

$$\text{Moss liftings are always monotone [20, Proposition 24]. We show that they also index the Moss lifting so that the predicate lifting interpreting Boolean operators. Concretely, this works as follows. For readability, we denote is separating, it is clear that the Moss liftings are expressible using $\pi$.

Combining $\nabla$ with the presentation of $\mathcal{M}_\omega$ (Example 2.4) produces, for each choice of numbers $n \geq 0$ and $k_1, \ldots, k_n \geq 0$, a $\sum_{i=1}^n k_i$-ary Moss lifting $\lambda$ given by

$$\lambda((A_{ij})_{i=1,\ldots,n; j=1,\ldots,k_i}) = \{ \mathfrak{A} \in \mathcal{M}_\omega X \mid \forall i. \bigcup_j A_{ij} \in \mathfrak{A} \text{ and } \forall B \in \mathfrak{A}. \forall i. \exists j. B \cap A_{ij} \neq \emptyset \}.$$ 

Since $\mathcal{M}_\omega$ preserves finite sets and the box modality $\Box$ as described in Example 2.6 is separating, it is clear that the Moss liftings are expressible using $\Box$ and Boolean operators. Concretely, this works as follows. For readability, we denote the predicate lifting interpreting $\Box$ by $\Box$ as well, similarly for the dual modality $\Diamond$, so that $\Diamond_X(A) := \mathcal{M}_\omega \backslash \Box_X(X \setminus A) = \{ \mathfrak{A} \in \mathcal{M}_\omega X \mid \forall B \in \mathfrak{A}. B \cap A \neq \emptyset \}$. Then the Moss lifting $\lambda$ as described above can be written as

$$\lambda((A_{ij})) = \bigcap_{i} \Diamond_X(\bigcup_j A_{ij}) \cap \bigcap_{\pi} \Diamond_X(\bigcup_{i} A_{i \pi(i)})$$

where $\pi$ ranges over all selection functions assigning to each $i \in \{1, \ldots, n\}$ an index $\pi(i) \in \{1, \ldots, k_i\}$.

Moss liftings are always monotone [20, Proposition 24]. We show that they also preserve singletons:
Proposition 4.8. Moss liftings preserve singletons. More specifically, let \( \lambda \) be the Moss lifting induced by \( \tau/n \in \Sigma \). Then for all \( x_1, \ldots, x_n \in X \),

\[
\lambda_X(\{x_1\}, \ldots, \{x_n\}) = \{\tau_X(x_1, \ldots, x_n)\}.
\]

Marti and Venema already establish that the Moss liftings are separating [20, Proposition 25]; we show that they are even strongly expressive:

Proposition 4.9. The set \( \Lambda \) of all Moss liftings of \( T \) is strongly expressive.

Remark 4.10. Incidentally, this also means that for finitary functors the existence of a separating set of monotone predicate liftings is equivalent to the existence of a strongly expressive set of monotone singleton-preserving predicate liftings. The right-to-left implication is trivial; the converse follows from Proposition 4.8, Proposition 4.9, and the fact that for finitary functors the existence of a separating set of monotone predicate liftings is equivalent to the existence of a lax extension [20].

We have thus seen that given a fixed diagonal-preserving lax extension, from every natural transformation \( \tau : (-)^n \to T \) we obtain the corresponding Moss lifting \( \lambda^\tau/n \), which is a monotone singleton-preserving predicate lifting. Conversely, every monotone singleton-preserving predicate lifting \( \lambda \) yields a natural transformation \( \tau^\lambda : (-)^n \to T \) (Lemma 3.6.1). From Proposition 4.8, it is immediate that for \( \tau : (-)^n \to T \) we have

\[
\tau = \tau^{\lambda^\tau}.
\]

In particular, taking Moss liftings is an injection from functor operations to monotone singleton-preserving predicate liftings. Conversely, however, \( \lambda = \lambda^{\tau^\lambda} \) need not hold in general – recall that the construction of Moss liftings depends on the choice of a diagonal-preserving lax extension, and a functor may have more than one such extension. We report an example due to Paul Levy:

Example 4.11. Let \( M \) be the monoid of non-negative reals. This monoid in fact forms a division semiring in the expected sense (e.g. [39]), i.e. it is a semiring, and its non-zero elements form a multiplicative group. We note that every division semiring is refinable in the sense of Gumm and Schröder [15], i.e. \( n \) specified row sums \( b_1, \ldots, b_n \) and \( k \) specified column sums \( c_1, \ldots, c_k \) that induce the same total sum \( d = \sum b_i = \sum c_j \) can always be realized by some \( n \times k \)-matrix \( (a_{ij}) \) – in fact, one can just put \( a_{ij} = b_i c_j / d \). Now let \( b \in (0,1) \) be a transcendental number, and let \( N \subseteq M \) be generated by \( b \) in \( M \) as a division semiring. Concretely, elements of \( N \) have the form \( f(b)/g(b) \) where \( f(X) \) and \( g(X) \neq 0 \) are polynomials with non-negative rational coefficients. In particular, \( 1-b \notin N \); if we could write \( 1-b \) in the prescribed form \( f(b)/g(b) \), then by transcendentality of \( b \), \( f(X)/g(X) = 1-X \), in contradiction to the leading coefficients of \( f \) and \( g \) being positive.

Both \( M \) and \( N \) are positive (\( x + y = 0 \) implies \( x = y = 0 \)) and refinable, so that the monoid-valued functors \( F = M^{(-)} \) and \( G = N^{(-)} \) both preserve weak pullbacks [15]. As recalled above, it follows that in both cases, the Barr extension is functorial, in particular is a diagonal-preserving lax extension. Now
diagonal-preserving lax extensions are easily seen to be inherited by subfunctors, so that the Barr extension $F$ induces a diagonal-preserving lax extension $L$ of $G$. This extension differs from the Barr extension $G$; we immediately cast the counterexample in the form that interests us here:

Let $X = \{u, v\}$. Representing elements of $GX$ as formal linear combinations, we have a binary functor operation $\tau(x, y) = x + by$ for $G$. We write $\lambda^1$ and $\lambda^2$ for the Moss liftings induced from $\tau$ via $G$ and via $L$, respectively (by the above, both $\lambda^1$ and $\lambda^2$ induce $\tau$). Then $u + bv \in \lambda^1(\{u, v\}, \{u\})$ but $u + bv \notin \lambda^2(\{u, v\}, \{u\})$: For the former, we have a unique witnessing element of $F \in X$, namely $((1 - b)(u, \{u, v\}) + b(v, \{u, v\}) + b(u, \{u\})$; but in $G \in X$, there is no witnessing element since $1 - b \notin N$.

Summing up, even for weak-pullback preserving functors, singleton-preserving monotone predicate liftings are not in general uniquely determined by the functor operation they induce. In the above example, both singleton predicate liftings inducing the given functor operation arise as Moss liftings, via different diagonal-preserving lax extensions; we currently do not know whether every singleton-preserving monotone predicate lifting is a Moss lifting for some diagonal-preserving lax extension.

Remark 4.12. It is fairly easy to see that for monotone singleton-preserving unary predicate liftings $\lambda$, we do have $\lambda = \lambda^1(\tau^+)$. 

5 Generic Expressions

We proceed to define, given a set of monotone and singleton-preserving predicate liftings for a functor $T$, syntactic expressions describing the behaviour of states of $T$-coalgebras. Our main result is a Kleene-type theorem stating that for every state of a $T$-coalgebra there exists an equivalent expression, and conversely, every expression describes the behaviour of some state of a finite $T$-coalgebra. As indicated above, our expression language is a small fragment of the coalgebraic $\mu$-calculus, essentially restricted to modalities and greatest fixed points $\nu z. \phi$.

Definition 5.1 (Expressions). We fix a set $V$ of fixed point variables and a set $\mathcal{L}$ of modalities equipped with an arity function $\text{ar} : \mathcal{L} \to \omega$; we write $L/n \in \mathcal{L}$ if $L \in \mathcal{L}$ and $\text{ar}(L) = n$. The set $\mathcal{E}$ of expressions $\phi, \ldots$ is then defined by the grammar

$$\phi ::= z \mid \nu z. \phi \mid L(\phi_1, \ldots, \phi_n) \quad (z \in V, L/n \in \mathcal{L}).$$

An expression is closed if all its fixed point variables are bound by a fixed point operator. An expression is guarded if all its fixed point variables are separated from their binding fixed point operator by at least one modality. We write $\mathcal{E}_0$ for the set of closed and guarded expressions. We have the usual notion of $\alpha$-equivalence of expressions modulo renaming of bound variables. An occurrence of a fixed point operator in an expression is top-level if it is not in scope of a modality.
We next define the semantics of expressions, which agrees with their interpretation as formulas in coalgebraic logic. We fix the requisite data:

**Assumption 5.2.** For the rest of the paper, we fix a set $\mathcal{L}$ of modalities and an assignment of a singleton-preserving monotone $n$-ary predicate lifting $[L]$ for $T$ to each $L/n \in \mathcal{L}$ such that the set $\Lambda := \{ [L] \mid L \in \mathcal{L} \}$ is strongly expressive.

By the results of the previous section, these assumptions imply that $T$ has a presentation and is thus finitary (Theorem 2.2).

**Definition 5.3 (Semantics).** Given a $T$-coalgebra $C = (X, \xi)$ and a valuation $\kappa : V \rightarrow QX$, the semantics $\mathcal{J}^C_\phi \subseteq X$ of expressions $\phi \in \mathcal{E}$ is given by

$$
\mathcal{J}^C_\nu z.\phi = \mathcal{J}^C_\phi \left[ \nu z.\phi/z \right]
$$

where as usual, we use $\nu$ to denote greatest fixed points of monotone maps. When $\phi$ is closed, we simply write $\mathcal{J}^C_\phi$ in lieu of $\mathcal{J}^C_\phi_\kappa$, and we drop the subscript $C$ whenever $C$ is clear from the context.

Note that since the predicate liftings $[L]$ are monotone and $\xi^{-1}$ is a monotone map, the requisite greatest fixed points exist by the Knaster-Tarski fixed point theorem. Moreover, the assumption that the predicate liftings are singleton-preserving will ensure that every expression describes exactly one behavioural equivalence class (see Theorem 5.15).

By dint of the fact that our expression language is contained in the coalgebraic $\mu$-calculus, the following is an immediate consequence of the fact that the latter is invariant under behavioural equivalence (e.g. [31]):

**Lemma 5.4 (Invariance under behavioural equivalence).** For every closed expression $\phi$ and coalgebras $C = (X, \xi)$, $D = (Y, \zeta)$, if states $x \in X$ and $y \in Y$ are behaviourally equivalent, then $x \in \mathcal{J}^C_\phi$ iff $y \in \mathcal{J}^D_\phi$.

**Lemma 5.5.** For all expressions $\phi \in \mathcal{E}$, $\mathcal{J}^C_\nu z.\phi = \mathcal{J}^C_\phi \left[ \nu z.\phi/z \right]$. 

**Example 5.6.** (1) For the deterministic automaton functor $TX = 2 \times X^A$ with $A = \{a, b\}$, we let $\mathcal{L}$ be the set of two binary modalities $\langle 0, a.(-), b.(-) \rangle$ and $\langle 1, a.(-), b.(-) \rangle$ (corresponding to the two Moss liftings of Example 4.7.1). We interpret expressions in the final $T$-coalgebra $\nu T$ carried by all formal languages over $A$. Here are a few closed and guarded expressions and their semantics in $\nu T$ (as usual $|w|_b$ denotes the number of $b$'s in $w$):

$$
\begin{align*}
[\nu v. \langle 0, a.v, b.v \rangle] &= \emptyset \\
[\nu z. \langle 1, a.z, b.z \rangle] &= \{ A^* \} \\
[\nu x. \langle 1, a.x, b.\nu y. \langle 0, a.y, b.x \rangle \rangle] &= \{ w \in A^* \mid |w|_b \text{ even} \}
\end{align*}
$$
Note that the semantics of each of these expressions is a singleton (up to behavioural equivalence); in fact, for an arbitrary \( T \)-coalgebra \( X \), the semantics of the above expressions is the set of states accepting the language in the singleton on the right. In Lemma 5.12 further below we prove that this holds in general.

(2) Consider \( T = \mathcal{P}_\omega(A \times -) \) where \( A \) is a finite set of labels. A presentation of \( T \) is given by the signature containing for each \( n \)-tuple \( \vec{a} = (a_1, \ldots, a_n) \in A^n \) one \( n \)-ary operation symbol, and the corresponding natural transformation \( \tau_{\vec{a}} : (-)^n \to T \) is defined by

\[
\tau_{\vec{a}}^X : (x_1, \ldots, x_n) \mapsto \{(a_1, x_1), \ldots, (a_n, x_n)\}.
\]

The corresponding Moss lifting is \( \lambda_{\vec{a}}/n \) given by

\[
\lambda_{\vec{a}}^X(Y_1, \ldots, Y_n) = \{Z \in \mathcal{P}_\omega(A \times X) \mid Z \subseteq \bigcup_{i=1}^{n} (\{a_i\} \times Y_i) \text{ and } Z \cap \{a_i\} \times Y_i \neq \emptyset \text{ for } i = 1, \ldots, n\}
\]

(cf. (3.1)). Now put \( \mathcal{L} = \{[\vec{a}]/n \mid \vec{a} \in A^n, n \in \omega\} \) and interpret each \([\vec{a}]\) by \( \lambda_{\vec{a}} \).

For example, for \( A = \{a, b\} \) the expression \( \nu x. [a][a, b, a](x, ([], [])) \), where \([[]]\) is the unique nullary modality in \( \mathcal{L} \), describes the left-hand state in the following labelled transition system

\[
\begin{align*}
\xymatrix{\& a, b \\
& \circ \ar[ld]^{a} \ar[rd]^{b} & \\
& \circ \ar[r] & \circ}
\end{align*}
\]

(3) For \( T = \mathcal{D} \) we have the presentation with an \( n \)-ary operation \( \tau_{\vec{p}} \) for every \( \vec{p} = (p_1, \ldots, p_n) \) with \( \sum_{i=1}^{n} p_i = 1 \) and corresponding Moss liftings as described in Example 4.7.3. For each such \( \vec{p} \), we introduce a modality \([\vec{p}]/n \in \mathcal{L} \), and interpret it as \( \lambda_{\vec{p}} \). Now consider the Markov chain (i.e. \( \mathcal{D} \)-coalgebra)

\[
\begin{align*}
\xymatrix{\& a, b, c \\
& \circ \ar[ld]^{a} \ar[rd]^{b} \ar[d]^{c} & \\
& \circ \ar[r] & \circ \ar[r] & \circ}
\end{align*}
\]
The behaviour of the left-hand state is described by the expression
\[ \nu x. [2/3, 1/3] (x, \nu y. [1/6, 1/3, 1/2] (x, y, \nu z. [1/4, 3/4] (x, z))). \]

**Remark 5.7.** The syntax of our expressions is determined purely by the finitary coalgebraic type functor, more precisely, by a given strongly expressive set \( \Lambda \) of monotone singleton-preserving predicate lifting. In contrast, existing expression calculi such as standard regular expressions for deterministic automata or the coalgebraic expression calculi in \([34,32]\) use extra operations (e.g. expressing union or concatenation of languages). These operations are not dictated by the setting, viz. an endofunctor on \( \text{Set} \). Rob Myers’ PhD thesis \([25]\) explains nicely how such extra operations are obtained naturally in an expression calculus when one works over an algebraic category (such as the one of join-semilattices or vector spaces over the reals, i.e. algebras for the monad \( R^\langle - \rangle \)). We leave the extension of our expression language to this more general setting for future work.

Our Kleene theorem requires a number of technical lemmas:

**Lemma 5.8.** Let \( \lambda/n \) and \( \lambda'/n' \) be monotone singleton-preserving predicate liftings for \( T \). Let \( S \) be an equivalence relation on a set \( X \), let \( A_1, \ldots, A_n \) be \( S \)-equivalence classes or empty, and let \( B_1, \ldots, B_n' \) be \( S \)-closed subsets of \( X \). Then the following holds.

1. \( \lambda X(A_1, \ldots, A_n) \subseteq \lambda' X(B_1, \ldots, B_n') \) or \( \lambda X(A_1, \ldots, A_n) \setminus \lambda' X(B_1, \ldots, B_n') = \emptyset \).
2. If the \( B_1, \ldots, B_n' \) are even \( S \)-equivalence classes or empty, then
\[ \lambda X(A_1, \ldots, A_n) = \lambda' X(B_1, \ldots, B_n') \] or \( \lambda X(A_1, \ldots, A_n) \setminus \lambda' X(B_1, \ldots, B_n') = \emptyset \).

**Proof (Sketch).** Apply naturality to the quotient map \( q : X \rightarrow X/S \).

In the proof of Lemma 5.12 further below, we will make use of an \( \Lambda \)-bisimulation. We briefly recall the essentials of this notion \([12]\):

**Definition 5.9 (\( \Lambda \)-Simulation).** Given a pair of \( T \)-coalgebras \((X, \xi)\) and \((Y, \zeta)\), a \( \Lambda \)-simulation is a relation \( S \subseteq X \times Y \) such that for all predicate liftings \( \lambda \in \Lambda \) and \( X_i \subseteq X \), \( x S y \) implies
\[ \xi(x) \in \lambda X(X_1, \ldots, X_n) \Rightarrow \zeta(y) \in \lambda Y(S[X_1], \ldots, S[X_n]). \]

A \( \Lambda \)-bisimulation is a \( \Lambda \)-simulation \( S \) such that \( S^\circ \) is also a \( \Lambda \)-simulation. Elements \((x, y) \in X \times Y\) are \( \Lambda \)-bisimilar if there is a \( \Lambda \)-bisimulation relating \( x \) and \( y \).

**Theorem 5.10.** \( \Lambda \)-bisimilarity coincides with behavioural equivalence.

**Remark 5.11.** In fact, for Theorem 5.10 it is sufficient that \( \Lambda \) is separating and the predicate liftings in \( \Lambda \) are monotone. It turns out that Theorem 5.10 is actually a special case of \([20, Theorem 11]\), applied to the case where the lax extension is induced by a separating set of monotone predicate liftings.
Lemma 5.12. Let \((X, \xi)\) be a \(T\)-coalgebra, let \(\lambda_i/k \in \Lambda, i = 1, \ldots, k\), and let \((A_1, \ldots, A_k)\) be the greatest fixed point of the map \(h : (\mathcal{Q}X)^k \to (\mathcal{Q}X)^k\) defined by
\[
\begin{pmatrix}
X_1 \\
\vdots \\
X_k
\end{pmatrix} 
\mapsto 
\begin{pmatrix}
\xi^{-1}[\lambda_1, X(1, \ldots, X_k)] \\
\vdots \\
\xi^{-1}[\lambda_k, X(1, \ldots, X_k)]
\end{pmatrix}.
\tag{5.1}
\]
Then for each \(i\), all elements of \(A_i\) are behaviourally equivalent, and for all \(i, j\), either \(A_i \cap A_j = \emptyset\) or \(A_i = A_j\).

(In the above lemma, we restrict to all \(\lambda_i\) having full arity \(k\) and using their arguments in the given order only in the interest of readability; this is w.l.o.g. since we can just reorder arguments and add dummy arguments.)

Proof (Sketch). Let \(S \subseteq X \times X\) be the relation
\[
S = \{ (x_1, x_2) \mid \exists A_i. x_1 \in A_i \land x_2 \in A_i \} \cup \Delta_X.
\]
Using Lemma 5.8 one shows first that \(S\) is an equivalence relation, which already takes care of the second part of the claim, and then that \(S\) is a \(\Lambda\)-bisimulation.
The first claim of the lemma then follows by Theorem 5.10.

The final ingredient of our Kleene-type correspondence is the following adaptation of Bekič’s bisection lemma [6]:

Lemma 5.13. For complete lattices \((X, \leq), (Y, \leq)\) and for every pair of monotone maps \(f : X \times Y \to X\) and \(g : X \times Y \to Y\), we have
\[
\nu(x, y).(f(x, y), g(x, y)) = (x_0, y_0) \quad \text{with} \quad x_0 = \nu x. f(x, \nu y. g(x, y))
\]
\[
y_0 = \nu y. g(x_0, y).
\]
Although in [6] this lemma only covers least fixed points in a slightly different setting, the proof is the same. For completeness, we provide it in the appendix.

Using Lemma 5.13 we can transform every expression \(\phi \in \mathcal{E}_0\) into a system of flat equations \((z_1 = \phi_1, \ldots, z_k = \phi_k)\) for some \(k \in \omega\), i.e. equations without nested modalities or fixed point operators: This is done by first ensuring that every fixed point operator uses a different fixed point variable and then binding every modality that is not nested directly under a fixed point operator with a fresh variable. Thus we can rewrite every expression \(\phi \in \mathcal{E}_0\) in the form
\[
\phi \equiv \nu\nu z_1. L_1(z_1, \nu z_2. L_2(\ldots), \nu z_k. L_k(\ldots))
\]
for some modalities \(L_i \in \mathcal{L}, i = 1, \ldots, k\). If we now inductively apply Lemma 5.13 and, for readability, additionally normalize every modality to have as many arguments as there are different fixed point variables in such an expression, introducing dummy arguments where necessary, then we can write \(\phi\) as a system
\[
\begin{align*}
z_1 &= L_1(z_1, z_2, \ldots, z_k) \\
z_2 &= L_2(z_1, z_2, \ldots, z_k) \\
&\vdots \\
z_k &= L_k(z_1, z_2, \ldots, z_k)
\end{align*}
\tag{5.2}
\]
of flat equations. Given any coalgebra $C = (X, \xi)$, the above system induces an obvious map of the form (5.1) (replacing $z_i$ by $X_i$ and $L_i$ by $\lambda_i = \llbracket L_i \rrbracket$), and the first components of its greatest fixed point is the semantics $\llbracket \phi \rrbracket_C$. The following example shows a concrete case.

**Example 5.14 (Applying Bekič’s bisection lemma).** Consider the expression

$$\phi = \nu x. L_1(x, L_2(x), \nu y. L_3(y, L_2(z)))$$

In order to transform it as per the procedure indicated, we first need to add a fixed point operator with a fresh variable to the first occurrence of $L_2$:

$$\phi = \nu x. L_1(x, \nu w. L_2(x), \nu y. L_3(y, \nu z. L_2(z)))$$

Then we can form the equation system for the variables $x, w, y, z$

$$x = L_1(x, w, y, z) = L_1(x, w, y)$$
$$w = L_2(x, w, y, z) = L_2(x)$$
$$y = L_3(x, w, y, z) = L_3(y, z)$$
$$z = L_4(x, w, y, z) = L_2(z)$$

where we extend $\mathcal{L}$ with additional operators $\bar{L}_i$ having dummy arguments, defined as indicated. The semantics of this equation system in a coalgebra $C = (X, \xi)$ is defined as the greatest fixpoint $(A_0, A_1, A_2, A_3)$ of the map $h : Q^n X \to Q^n X$ defined by

$$h : \begin{pmatrix} X_1 \\ X_2 \\ X_3 \\ X_4 \end{pmatrix} \mapsto \begin{pmatrix} \xi^{-1}[L_1]X(X_1, X_2, X_3) \\ \xi^{-1}[L_2]X(X_1) \\ \xi^{-1}[L_3]X(X_2, X_4) \\ \xi^{-1}[L_4]X(X_4) \end{pmatrix}.$$ 

The semantics of $\phi$ in $C$ is then $\llbracket \phi \rrbracket_C = A_0$.

The following two results together establish a Kleene-type correspondence for the generic expressions of Definition 5.1.

**Theorem 5.15.** Every expression $\phi \in \mathcal{E}_0$ describes exactly one behavioural equivalence class, which is moreover realized in a finite coalgebra. Explicitly: there exists a state $x$ in a finite coalgebra $C = (X, \xi)$ such that for every coalgebra $C$, $\llbracket \phi \rrbracket_C$ contains precisely the states of $C$ that are behaviourally equivalent to $x$.

**Proof (Sketch).** By Lemma 5.4, it suffices to show that any two states (w.l.o.g. in the same coalgebra, using coproducts) satisfying $\phi$ are bisimilar. Since $\phi$ can transformed into a system (5.2) of flat equations, this follows by Lemma 5.12. Realization in a finite coalgebra follows from the finite model property of the coalgebraic $\mu$-calculus [8], and alternatively is shown by constructing a model from the variables in a flat equation system. 

**Theorem 5.16.** Let $C = (X, \xi)$ be a finite $T$-coalgebra. For every $x \in X$, there exists an expression $\phi \in \mathcal{E}_0$ such that $x \in \llbracket \phi \rrbracket_C$. 

Proof. Let $X = \{x_1, \ldots, x_k\}$ and w.l.o.g. $x = x_1$. Since $A$ is strongly expressive, for every $x_i \in X$ there is a modality $L_i$, w.l.o.g. with arity $k$ and prescribed argument ordering, such that

$$\{\xi(x_i)\} = [L_i]_X(\{x_1\}, \ldots, \{x_k\}).$$

That is, the $\{x_i\}$ solve the system $(x_i = L_i(x_1, \ldots, x_k))_{i=1,\ldots,k}$ of flat fixed point equations, so for the greatest fixed point $(A_1, \ldots, A_k)$ of the system, we have $x_i \in A_i$ for every $i$, in particular $x = x_1 \in A_1$. It now just remains to convert the equation system into an equivalent single expression in the standard manner [7] (incurring exponential blow-up); then $x \in [\sigma]_C$ as desired. □

Corollary 5.17. Every expression denotes a behavioural equivalence class of a state in a finite coalgebra, and conversely every such class is denoted by some expression.

Example 5.18. (1) For the functor $TX = 2 \times X^A$ for $A = \{a, b\}$ consider the coalgebra with carrier $X = \{x_1, x_2\}$ and with coalgebra structure $\xi : X \to 2 \times X^A$ with $\xi(x_0) = (1, (a \mapsto x_0, b \mapsto x_1))$ and $\xi(x_1) = (0, (a \mapsto x_1, b \mapsto x_0))$. Then we clearly have $\{\xi(x_1)\} = \lambda^1(\{x_1\}, \{x_2\})$ and $\{\xi(x_2)\} = \lambda^1(\{x_2\}, \{x_1\})$. Using the syntax of Example 5.6.1 and following the proof of Theorem 5.16, we obtain the following expression for the behavioural equivalence class (i.e. formal language) for $x_1$:

$$\nu x_1.\{1, a.x_1, b.\nu x_2.\{0, a.x_2, b.x_1\}\}.$$  

Note that this is the same expression (modulo $\alpha$-equivalence) as the third expression from Example 5.6.1.

(2) For the functor $P_L(A \times -)$ and $A = \{a, b\}$ the coalgebra $C = \{(x, y, z, w), \xi\}$ depicted in Example 5.6.2 satisfies the following equations:

$$\{\xi(x)\} = \lambda^2_c(\{y\}), \{\xi(y)\} = \lambda^2_{c}(a, b, c)(\{x, w, z\}), \{\xi(w)\} = \lambda^2_{c}(\emptyset), \{\xi(w)\} = \lambda^2_{c}(\emptyset)$$

By Theorem 5.16 $\{(x), \{y\}, \{z\}, \{w\}\}$ solves the following system, reusing the same variable names,

$$x = [a](y), \quad y = [a, b, a](x, w, z), \quad w = [\emptyset], \quad z = [\emptyset]$$

which can be transformed as demonstrated in Example 5.14 to the expression given in Example 5.6.2, describing the behaviour of the state $x$.

(3) For the functor $T = D$ consider the expression from Example 5.6.3: $\nu x.\{2/3, 1/3\}(x, \nu y.\{1/6, 1/3, 1/2\}(x, y, \nu z.\{1/4, 3/4\}(x, z)))$, which transforms to the system

$$x = [2/3, 1/3](x, y), \quad y = [1/6, 1/3, 1/2](x, y, z) = [1/4, 3/4](x, z).$$

By Theorem 5.15 we can construct a coalgebra $C = \{(x, y, z), \xi\}$ defined by:

$$\{\xi(x)\} = \lambda^4_{X}(\{x\}, \{y\})$$

$$\{\xi(y)\} = \lambda^4_{X}(\{x\}, \{y\}, \{z\})$$

$$\{\xi(z)\} = \lambda^4_{X}(\{x\}, \{z\})$$
which is exactly the coalgebra depicted in Example 5.6.3 where $x$ is in the behavioural equivalence class of the above expression.

An alternative approach to defining the semantics of expressions is to construct a $T$-coalgebra structure on the set $E_0$ of closed and guarded expressions, similarly as in the work of Silva et al. [34] and also Myers [25]. In Theorem 5.21 below we show that this new semantics coincides with the previous one.

**Definition 5.19.** We define a $T$-coalgebra $\varepsilon : E_0 \rightarrow TE_0$ inductively by

$$\varepsilon(L(\phi_1, \ldots, \phi_n)) \in [L](\{\phi_1\}, \ldots, \{\phi_n\}) \quad (5.3)$$

$$\varepsilon(\nu x.\phi) = \varepsilon(\phi[\nu x.\phi/x]). \quad (5.4)$$

This is actually a definition of $\varepsilon$ because (a) in (5.3), $[L]$ preserves singletons and thus there is only one element in $[L](\{\phi_1\}, \ldots, \{\phi_n\})$, and (b) for the inductive part (5.4), one can use the number of top-level fixed point operators as a termination measure, which decreases in each step because the fixed points are guarded.

Now recall that a coalgebra $\xi : X \rightarrow TX$ is locally finite if every $x \in X$ is contained in a finite subcoalgebra of $\xi$. Locally finite coalgebras are precisely the (directed) unions of finite coalgebras (see [21]). Thus, it follows from Theorem 5.16 that for any $x \in X$ in a locally finite coalgebra $\xi : X \rightarrow TX$, there exists a $\phi \in E_0$ with $x \in [\phi]_X$.

Moreover, $E_0$ is obviously not finite; however, arguing via finiteness of the Fischer-Ladner closure [16] we obtain

**Proposition 5.20.** The $T$-coalgebra $(E_0, \varepsilon)$ is locally finite.

The following theorem says that $(E_0, \varepsilon)$ serves as a canonical model of the expression language:

**Theorem 5.21.** For every closed and guarded expression $\phi \in E_0$ and every state $x$ in a $T$-coalgebra $C$, $x \in [\phi]_C$ iff $x$ is behaviourally equivalent to $\phi$ as a state in $(E_0, \varepsilon)$.

In particular, the above implies that

$$\phi \in [\phi]_{E_0} \quad \text{for all } \phi \in E_0, \quad (5.5)$$

essentially a truth lemma for $E_0$. For the proof of Theorem 5.21, we note:

**Lemma 5.22.** $\alpha$-Equivalent expressions are behaviourally equivalent as states in $(E_0, \varepsilon)$.

**Proof (Theorem 5.21, sketch).** It suffices to prove (5.5): The ‘if’ direction of the claim then follows from invariance of $\phi$ under behavioural equivalence (Lemma 5.4), and ‘only if’ is by Theorem 5.15. We generalize (5.5) to expressions $\phi$ with free variables: Whenever $\sigma$ is a substitution of the free variables of $\phi$ and $\kappa$ a valuation such that $\sigma(v) \in \kappa(v)$ for every free variable $v$ of $\phi$, then

$$\phi \sigma \in [\phi]_{E_0}.$$ 

We proceed by induction on $\phi$, using Lemma 5.22 in the fixpoint case. □
Remark 5.23. To give a concrete example use of the connection between expression languages and modal fixed point logics afforded by the above results, we note that we now obtain an alternative handle on equivalence of expressions that complements the standard approach via partition refinement: Expressions $\phi, \psi$ are equivalent iff some state described by $\phi$ (obtained, e.g., via the one of the model constructions in Theorems 5.15 and 5.21) satisfies $\psi$. Note that the latter is fairly easy to check as long as the modalities are computationally tractable, since $\psi$ otherwise involves only greatest fixed points. This approach is similar to reasoning algorithms in the lightweight description logic $\mathcal{EL}$ [4], where checking validity of $\phi \rightarrow \psi$ is reduced to model checking $\psi$ in a minimal model of $\phi$; we leave a more detailed analysis to future work.

6 Conclusion and Further Work

We have defined a generic expression language for behaviours of finite set coalgebras based on predicate liftings, specifically on a strongly expressive set of singleton-preserving predicate liftings. There are mutual conversions between such sets of predicate liftings and functor presentations, one direction being via the Moss liftings introduced by Marti and Venema [20]; we have however demonstrated that these fail to be mutually inverse in one direction, i.e. in general not all singleton-preserving predicate liftings are Moss liftings. Our language is presumably equivalent to the set-based instance of Myer’s expression language [25]; our alternative presentation is aimed primarily at showing that expression languages embed naturally into the coalgebraic $\mu$-calculus, generalizing well-known results on the relational $\mu$-calculus [14,10,35,2]. The benefit of this insight is to tighten the connection between expression languages and specification logics, e.g. it allows for combining model checking, equivalence checking, and reasoning within a single formalism. On a more technical note, we show, e.g., that one can provide an alternative semantics of expressions by defining a coalgebra structure on expressions, an approach pioneered by Silva et al. [34] and used also by Myers [25]; in the light of the expressions/logic correspondence, this construction is now seen as a canonical model construction for a fragment of the coalgebraic $\mu$-calculus, and the core part of the proof that the two semantics agree becomes just a truth lemma.

An important point for further work is to extend the current setup from the base category $\textbf{Set}$ to algebraic categories (such as join semi-lattices or positive convex algebras) in order to generalize our results to expression calculi involving convenient additional operations (reflecting the ambient algebraic theory) such as addition. A closely related point is the connection with coalgebraic determinization [33]; it should be interesting to see whether our ideas can lead to expression calculi for coarser system equivalences than bisimilarity, such as trace equivalence for transition systems or distribution bisimilarity for Segala systems. Such a generalization might be based on our recent approach to coalgebraic trace semantics via graded monads [22].
A Omitted Details and Proofs

Proof of Lemma 3.6

1.: First note that (3.2) is really a definition of $\tau_\lambda$ because $\lambda$ preserves singletons. Moreover, $\tau_\lambda$ is natural because for $f : X \to Y$ and $x_i \in X$,

$$\tau_\lambda,X(x_1, \ldots, x_n) \in \lambda_X([x_1], \ldots, [x_n]) \quad \text{(by definition)}$$

$$\subseteq \lambda_X(f^{-1}[[f(x_1)], \ldots, f^{-1}[[f(x_n)]]]) \quad \text{(\lambda monotone)}$$

$$= (Tf)^{-1}[\lambda_Y([f(x_1)], \ldots, [f(x_n)])] \quad \text{(naturality of \lambda)}$$

$$= (Tf)^{-1}[[\tau_\lambda,Y(f(x_1), \ldots, f(x_n))]] \quad \text{(by definition)}$$

$$\Rightarrow Tf(\tau_\lambda,x_1, \ldots, x_n) = \tau_\lambda,Y(f(x_1), \ldots, f(x_n))$$

2.: By the previous item, we obtain a natural transformation $\alpha = [\tau_\lambda]_{\lambda \in \Lambda}$, and strong expressivity implies that $\alpha$ is componentwise surjective. \hfill \Box

Proof of Proposition 4.8

Recall that $\lambda = \nabla^L \circ \tau Q$ by definition. Let $s_X : X \to QX$ be the function $s_X(x) = \{x\}$. Then we have

$$\lambda_X([x_1], \ldots, [x_n])$$

$$= \{t \in TX \mid (t, \tau_QX([x_1], \ldots, [x_n])) \in L(\in_X)\}$$

$$= \{t \in TX \mid (t, \tau_QX(s_X(x_1), \ldots, s_X(x_n))) \in L(\in_X)\}$$

$$= \{t \in TX \mid (t, Ts_X \circ \tau_X(x_1, \ldots, x_n)) \in L(\in_X)\}$$

$$= \{t \in TX \mid (t, \tau_X(x_1, \ldots, x_n)) \in L(\in_X; (Ts_X)^\lambda)\} \quad \text{ (Proposition 4.2)}$$

$$= \{t \in TX \mid (t, \tau_X(x_1, \ldots, x_n)) \in L(\Delta_X; s_X)\} \quad \text{ (s_X; \forall X = \Delta_X)}$$

$$= \{\tau_X(x_1, \ldots, x_n)\} \quad \Box$$

Proof of Proposition 4.9

Let $t \in TX$; we need to show that $\{t\} = \lambda([x_1], \ldots, [x_n])$ for some Moss lifting $\lambda$ and $x_1, \ldots, x_n \in X$. Since $\alpha : T_\Sigma \to T$ from our functor presentation of $T$ has surjective components, there exists some $\tau/n \in \Sigma$ such that $t = \alpha_X(x_1, \ldots, x_n) = \tau_X(x_1, \ldots, x_n)$ for some $x_1, \ldots, x_n \in X$. Because $L$ is a lax extension, we have $Ts_X \subseteq Ls_X \subseteq L(\in_X)$ for the function $s_X : x \mapsto \{x\}$ and thus

$$(t, Ts_X(t)) = (t, \tau_QX([x_1], \ldots, [x_n])) \in L(\in_X)$$

since $Ts_X(t) = Ts_X(\tau_X(x_1, \ldots, x_n)) = \tau_QX(s_X(x_1), \ldots, s_X(x_n))$. Thus $t \in \lambda([x_1], \ldots, [x_n])$ (see Definition 4.6), and since Moss liftings preserve singletons, we conclude $\{t\} = \lambda([x_1], \ldots, [x_n])$ as desired. \hfill \Box
We show that $\lambda = \lambda^{(r^\lambda)}$ for monotone singleton-preserving unary predicate liftings $\lambda$. Let $\lambda$ and $\lambda'$ be predicate liftings that agree on singletons. Now for any $X$ and $A \subseteq X$ consider the characteristic map $\chi_A : X \rightarrow 2 = \{\bot, \top\}$, which satisfies $A = \chi_A^{-1}(\top)$. Then using naturality and the fact that $\lambda_2(\{\top\}) = \lambda'_2(\{\top\})$, we have

$$\lambda_X(A) = \lambda_X(\chi_A^{-1}(\{\top\})) = (T\chi_A)^{-1}(\lambda_2(\{\top\}))$$

$$= (T\chi_A)^{-1}(\lambda'_2(\{\top\})) = \lambda_X'(\chi_A^{-1}(\{\top\})) = \lambda_X'(A).$$

Now observe that $\lambda$ and $\lambda^{(r^\lambda)}$ agree on singletons, thus they are equal as desired.

**Proof of Lemma 5.5**

First we prove that for any expression $\phi \in \mathcal{E}$ that does not contain free variables that are bound in another expression $\psi \in \mathcal{E}$ the following holds:

$$[\psi]^\kappa[z^{11}\phi] = [\psi[z/\phi]]^\kappa \quad (A.1)$$

Induction on $\psi$. If $\psi = x \neq z$ then $[x]^\kappa[z^{11}\phi] = [x]^\kappa = [x[z/\phi]]^\kappa$; if $\psi = z$ then $[z]^\kappa[z^{11}\phi] = [z[z/\phi]]^\kappa$; for $\psi = L(\phi_1, \ldots, \phi_n)$:

$$[L(\psi_1, \ldots, \psi_n)]^\kappa[z^{11}\phi] = \xi^{-1}[L(\psi_1[z^{11}\phi], \ldots, \psi_n[z^{11}\phi])]_{T_1}$$

$$\Rightarrow [\nu \psi_1][z^{11}\phi] = [\nu \psi_1[z/\phi]]^\kappa \quad (A.2)$$

where the last equation holds because of the assumption that the free variables of $\phi$ are not bound in $\psi$.

It follows that

$$[\nu \phi] = [\nu \phi[z^{11}\phi]] = [\phi[z^{11}\phi]]^\kappa \quad (A.3)$$

**Proof of Lemma 5.8**

Denote by $q : X \rightarrow X/S$ the canonical quotient map, let $C_1, \ldots, C_m \subseteq X$ be $S$-closed, and let $\lambda/m$ be monotone and preserve singletons. Then $C_i = q^{-1}[q[C_i]]$ for all $i$. Therefore, we have for every $t \in QT X$:

$$t \in \lambda_X(C_1, \ldots, C_m) = \lambda_X(q^{-1}[q[C_1]], \ldots, q^{-1}[q[C_m]])$$

$$\Rightarrow t \in (Tq)^{-1}[\lambda_{X/S}(q[C_1], \ldots, q[C_m])]$$

$$\Rightarrow Tq(t) \in \lambda_{X/S}(q[C_1], \ldots, q[C_m]).$$
(1) If there is some \( t \in \lambda_X(A_1, \ldots, A_n) \cap \lambda'_X(B_1, \ldots, B_{n'}) \), then we show the inclusion. For \( s \in \lambda_X(A_1, \ldots, A_n) \), (A.2) provides

\[ \{Tq(t), Tq(s)\} \subseteq \lambda_{X/S}(q[A_1], \ldots, q[A_n]) \]

Every \( A_i \subseteq X \) is an \( S \)-equivalence class or empty, so \( q[A_i] \) is at most a singleton. By monotonicity and singleton preservation of \( \lambda \), the right-hand side is at most a singleton, and thus \( Tq(t) = Tq(s) \). Applying (A.2) to \( t \) and \( B_1, \ldots, B_{n'} \), we have \( Tq(s) = Tq(t) \in \lambda'(q[B_1], \ldots, q[B_{n'}]) \), and consequently \( s \in \lambda'(B_1, \ldots, B_{n'}) \), again by (A.2).

(2) In the case where the sets are not disjoint, the equality is obtained by proving both inclusions using point (1). \( \square \)

**Proof of Lemma 5.12**

Let \( S \subseteq X \times X \) be the relation

\[ S = \{(x_1, x_2) \mid \exists A_i, x_1 \in A_i \land x_2 \in A_i \} \cup \Delta_X \]

(1) We prove that \( S \) is an equivalence relation. Let \( \overline{S} \) be the equivalence relation generated by \( S \), and let \( \overline{A_i} \) be the \( S \)-closure of \( A_i \). Then the \( \overline{A_i} \) are also \( S \)-closed, and we have

\[ \overline{S} = \{(x_1, x_2) \mid \exists \overline{A_i}, x_1 \in \overline{A_i} \land x_2 \in \overline{A_i} \} \cup \Delta_X \]

It follows that each \( \overline{A_i} \) is either empty (if \( A_i = \emptyset \)) or else an \( \overline{S} \)-equivalence class.

Now we show that \((\overline{A_1}, \ldots, \overline{A_k})\) is a post-fixed point of \( h \): Because \((A_1, \ldots, A_n)\) is a fixed point and the \( \lambda_i \) are monotone, we have

\[ A_j = \xi^{-1}[\lambda_{j,X}(A_1, \ldots, A_k)] \subseteq \xi^{-1}[\lambda_{j,X}((\overline{A_1}, \ldots, \overline{A_k}))] \quad \text{for all } j. \quad (A.3) \]

We will show that the post-fixed point condition

\[ \overline{A_j} \subseteq \xi^{-1}[\lambda_{j,X}(\overline{A_1}, \ldots, \overline{A_k})] \quad (A.4) \]

holds for all \( j \). To see this, it suffices by (A.3) and the definition of \( \overline{A_j} \) to show that whenever \( A_i \cap A_p \neq \emptyset \), then

\[ \lambda_{i,X}(\overline{A_1}, \ldots, \overline{A_k}) = \lambda_{p,X}(\overline{A_1}, \ldots, \overline{A_k}). \quad (A.5) \]

So let \( x \in A_i \cap A_p \). Then by (A.3), \( \xi(x) \in \lambda_{i,X}(\overline{A_1}, \ldots, \overline{A_k}) \cap \lambda_{p,X}(\overline{A_1}, \ldots, \overline{A_k}) \), and therefore (A.5) follows by Lemma 5.8.2.

Having shown that \((\overline{A_1}, \ldots, \overline{A_k})\) is a post-fixed point of \( h \), we obtain that \( \overline{A_i} \subseteq A_i \) for all \( i \), which implies that \( S = \overline{S} \) is an equivalence relation. Hence every \( A_i \) is either empty or an equivalence class of \( S \), whence \( A_i \cap A_j = \emptyset \) or \( A_i = A_j \) holds for all \( i, j \) as claimed in the second part of the lemma.

(2) Now we prove that \( S \) is a \( S \)-bisimulation, i.e. \( x S y \) and \( \xi(y) \in \lambda_X(B_1, \ldots, B_{n'}) \) implies \( \xi(y) \in \lambda_X(S[B_1], \ldots, S[B_{n'}]) \) for every \( \lambda/n \in A \) and \( B_j \subseteq X \). By Theorem 5.10, this implies the first claim of the lemma, since \( x, y \in A_j \) implies \( x S y \) by construction of \( S \).
By point (1), \( S \) is an equivalence relation, so \( S[B_j] = \overline{B_j} \supseteq B_j \) is the \( S \)-closure of \( B_j \); and since \( \lambda \) is monotone, \( \xi(x) \in \lambda_X(\overline{B_1}, \ldots, \overline{B_n}) \). Further, \( x \in S \) implies that either \( x = y \), in which case there is nothing to prove, or there exists \( j \) such that \( x, y \in A_j \) and therefore

\[
\xi(x), \xi(y) \in \lambda_{J \times A_1, \ldots, A_k}.
\]

Because \( \xi(x) \) also lies in \( \lambda_X(\overline{B_1}, \ldots, \overline{B_n}) \), we obtain

\[
\lambda_{J \times A_1, \ldots, A_k} \subseteq \lambda_X(\overline{B_1}, \ldots, \overline{B_n})
\]

by Lemma 5.8, and thus \( \xi(y) \in \lambda_X(S[B_1], \ldots, S[B_n]). \)

**Proof of Lemma 5.13**

By Tarski, all fixed points exist. \( (x_0, y_0) \) is a fixed point of \( \langle f, g \rangle : X \times Y \to X \times Y \), because \( y_0 = g(x_0, y_0) \) and thus also

\[
x_0 = f(x_0, \nu y.g(x_0, y)) = f(x_0, g(x_0, y_0)) = f(x_0, y_0).
\]

For any other fixed point \( (x', y') \) of \( \langle f, g \rangle \), we have

\[
x' = f(x', y') = f(x', g(x', y')) \leq f(x', \nu y.g(x', y)),
\]

so \( x' \leq x_0 \) and furthermore \( y' = g(x', y') \leq g(x_0, y') \leq \nu y.g(x_0, y). \)

**Proof of Theorem 5.15**

We first show that \( \phi \) denotes a single behavioural equivalence class, i.e. (i) we have invariance under behavioural equivalence (Lemma 5.4) and (ii) two states satisfying \( \phi \) are bisimilar. In order to prove (ii) we may w.l.o.g. assume that the two states live in the same coalgebra; indeed, given two coalgebras \( C \) and \( D \) and states \( x \) in \( C \) and \( y \) in \( D \) satisfying \( \phi \), then \( \text{inl}(x), \text{inr}(y) \) in \( C + D \) are behaviourally equivalent to \( x \) and \( y \), respectively, thus both satisfy \( \phi \) by Lemma 5.4.

Now let \( C = (X, \xi) \) be a \( T \)-coalgebra; we need to show that any two elements of \( [\phi]_C \) are behaviourally equivalent. As noted above, we can transform \( \phi \) into a system (5.2) of flat equations, and \( [\phi]_C \) is the first component of the greatest fixed point of the corresponding map of the form (5.1). The claim then follows by Lemma 5.12.

It remains to show that there exists a finite coalgebra \( C \) such that \( [\phi]_C \neq \emptyset \). This is immediate from the finite model property of the coalgebraic \( \mu \)-calculus [8]; alternatively, avoiding such overkill, it is seen as follows: We define \( C = (X, \xi) \) on the set \( X = \{x_1, \ldots, x_k\} \) of the variables in the above flat equation system by \( \xi(x_i) \in [L_i]_X(\{x_1\}, \ldots, \{x_k\}) \) where \( \phi_i = L_i(x_1, \ldots, x_k) \). Then by construction, \( \{x_1\}, \ldots, \{x_k\} \) is a fixed point of the equation system, hence contained in the greatest fixed point, which proves the desired non-emptiness of the greatest fixed point.
Proof of Proposition 5.20

Recall that the Fischer-Ladner closure of a \( \mu \)-calculus formula is standardly defined as the closure under subformulas, negation, and fixed point unfolding. In the absence of negation, we adapt the definition to include only closure under subformulas and fixed point unfolding. We then, of course, inherit the standard result that the Fischer-Ladner closure is finite [16]. Now by construction of \( \epsilon \), the subcoalgebra of \((E_0, \epsilon)\) generated by \( \phi \in E_0 \) contains only states from the Fisher-Ladner-closure of \( \phi \), hence is finite. \( \square \)

Proof of Theorem 5.21

It suffices to prove the truth lemma (5.5): The ‘if’ direction of the claim then follows from invariance of \( \phi \) under behavioural equivalence (Lemma 5.4), and ‘only if’ is by Theorem 5.15.

We strengthen (5.5) to a claim on expressions \( \phi \) possibly having free variables: Whenever \( \sigma \) is a substitution of the free variables of \( \phi \) and \( \kappa \) a valuation such that \( \sigma(v) \in \kappa(v) \) for every free variable \( v \) of \( \phi \), then
\[
\phi_{\sigma} \in [\phi]_{\kappa}^E. \tag{A.6}
\]

We prove (A.6) by induction over \( \phi \). The case for fixed point variables is just by the assumption on \( \sigma \) and \( \kappa \). For the modal case, we calculate as follows:

\[
L(\phi_1, \ldots, \phi_n)_{\sigma} = L(\phi_1\sigma, \ldots, \phi_n\sigma)
\]

\[
\in \epsilon^{-1}[L](\{\phi_1\sigma_1\}, \ldots, \{\phi_n\sigma\}) \quad \text{(by definition)}
\]

\[
\subseteq \epsilon^{-1}[L](\{\phi_1\}_{\kappa}, \ldots, \{\phi_n\}_{\kappa}) \quad \text{(induction, monotonicity)}
\]

\[
= [L(\phi_1, \ldots, \phi_n)]_{\kappa}^E. \quad \text{(semantics)}
\]

Finally, for the fixed point case \( \nu x. \phi \), first note that by Lemma 5.22, we can assume that \( x \) does not occur as a free variable in \( \sigma(v) \) for any free variable \( v \) of \( \phi \). Moreover, since \( x \) is not free in \( \nu x. \phi \), \( \sigma \) does not touch \( x \). Thus, \( (\nu x. \phi)_{\sigma} = \nu x. (\phi_{\sigma}) \). By construction of \( \epsilon \), \( (\nu x. (\phi_{\sigma}) \) is, as a state of \( E_0 \), behaviourally equivalent to \( \phi_{\sigma}[\nu x. \phi_{\sigma}/x] \), which by the inductive hypothesis is contained in \( [\phi]_{\kappa}^E \) where \( \kappa \) arises from \( \kappa \) by assigning to \( x \) the value \( \{\nu x. \phi_{\sigma}\} = \{(\nu x. \phi)_{\sigma}\} \). This shows that \( \{(\nu x. \phi)_{\sigma}\} \) is a post-fixed point of the map defining \( [\nu x. \phi]_{\kappa}^E \), and hence contained in \( [\nu x. \phi]_{\kappa}^E \), which proves the claim. \( \square \)

Proof of Lemma 5.22

Let \( \pi_{\alpha} : E_0 \to E_0/\alpha \) denote the quotient map of \( E_0 \) modulo \( \alpha \)-equivalence. Paralleling the definition of \( \epsilon \), we define a \( T \)-coalgebra structure \( \epsilon_{\alpha} \) on \( E_0/\alpha \) by

\[
\epsilon_{\alpha}(\pi_{\alpha}(L(\phi_1, \ldots, \phi_n))) \in [L](\{\pi_{\alpha}(\phi_1)\}, \ldots, \{\pi_{\alpha}(\phi_n)\})
\]

\[
\epsilon(\pi_{\alpha}(\nu x. \phi)) = \epsilon(\pi_{\alpha}(\phi[\nu x. \phi/x])).
\]
One sees in largely the same way as for $\varepsilon$ that this is actually a definition, noting additionally that $\alpha$-equivalent transformations of a formula $L(\phi_1, \ldots, \phi_n)$ necessarily happen in its arguments $\phi_i$ and that the number of top-level fixed point operators is invariant under $\alpha$-equivalence. We are done once we show that $\pi_\alpha : (E_0, \varepsilon) \rightarrow (E_0/\alpha, \varepsilon_\alpha)$ is a coalgebra morphism. We proceed by case distinction over the shape of states $\phi \in E_0$:

First assume that $\phi$ has the form $\phi = L(\phi_1, \ldots, \phi_n)$. We have to show $T\pi_\alpha(\varepsilon(L(\phi_1, \ldots, \phi_n))) \in [L](\{\pi_\alpha(\phi_1)\}, \ldots, \{\pi_\alpha(\phi_n)\})$. By naturality, this is equivalent to $\varepsilon(L(\phi_1, \ldots, \phi_n)) \in [L](\pi_\alpha^{-1}(\{\pi_\alpha(\phi_1)\}), \ldots, \pi_\alpha^{-1}(\{\pi_\alpha(\phi_n)\}))$, which follows by monotonicity from the fact that $\varepsilon(L(\phi_1, \ldots, \phi_n)) \in [L](\{\phi_1\}, \ldots, \{\phi_n\})$ by definition.

Second, assume that $\phi$ has the form $\phi = \nu x.\psi$. We proceed by induction on the number of top-level fixed point operators in $\phi$: We have

$$T\pi_\alpha(\varepsilon(\nu x.\psi)) = T\pi_\alpha(\varepsilon(\psi[\nu x.\psi/x]))$$

(by definition)

$$= \varepsilon_\alpha(\pi_\alpha(\psi[\nu x.\psi/x]))$$

(induction)

$$\varepsilon_\alpha(\pi_\alpha(\nu x.\psi))$$

(by definition)

Since $\phi$ is closed, these are the only cases. \qed
