Abstract: The growing demand for water resources is associated with many natural and anthropogenic factors: diversification of the economy, growth of water supply and requirements, construction of hydropower complexes, problems with managing the transboundary rivers waters, restoration of the ecology of the Aral Sea region and others. Now much attention is paid to the distribution of irrigation water during the growing season including the introduction of drip and spring irrigation systems, irrigation pipelines, etc. But, unfortunately, attention remains to the issues of effective salt leaching management on the land to the extent of soil salinity, crop variety, the composition of salts and salinity. In this paper, the authors attempt to solve this problem.

Keywords: salinity, irrigation, water shortage, salt leaching, mechanical composition of soil, hydromodule areas.

Introduction. Taking into account the zonal soil-climatic features of our Republic, special attention should be paid to the implementation of autumn-winter measures to improve the meliorative state of lands. To this end, it is necessary to carry out the following agrotechnical measures: plowing, leaching of saline lands, operational land planning, cutting of ridges and deep tillage.

In order to increase the efficiency of irrigated lands and to obtain the planned harvest of agricultural crops in the Republic, 690 thousand of saline land should be washed annually using palovas (checks), including 141 000 hectares in the Republic of Karakalpakstan, 181 thousand hectares in the Bukhara region and in the Kharezem region is 134 thousand hectares, etc [1;2;3;].

According to the data, 45% of the lands on the territory of Uzbekistan are saline to some extent. 34% of them are saline, which is 8%. The remaining lands are saline and highly saline. Usually in 100 grams of soil contains 0.3% chlorine of the ion, if the salts are not used 0.01 means the land is not saline, if the salt concentration exceeds 1%, chlorine ion 0.1-0.15% is considered highly saline. From previous experiments it is known that when salinization of the land the yield decreases by 10-15% for slightly saline soils, 30-35% for saline lands, 65-75% for highly saline soils, and further the yield decreases. Accordingly, the quality of agricultural products also decreases [5;6;].
Without reducing salinity in the root zone of the soil, a good harvest of cotton and other crops cannot be achieved. This can be achieved by leaching the land. The rate of irrigation is not continuous, if it is supplied in part, then the effectiveness of reducing the degree of salinization of land will increase. Therefore, when flushing land, especially if washed with large norms, after each water supply, it is necessary to take a break. The duration of the break varies from the connection of the soil texture and the filtration rate, respectively, in light soils water permeability is 2-3 days, medium soils 5-6 days and heavy soils 7-8 days[7;8;9;10].

It is possible to choose ways of leaching according to the degree of soil salinity, the physical properties of the soil and the relief of the field: by flooding, by furrows, by strips. The main method of land leaching is flooding with water, leaching is carried out by not passing water from one floor to another. At the present time, in the period of irrigation water shortage, the scientific justification of land leaching and ways of leaching to improve the efficiency of reducing the salinization of irrigated land becomes an urgent task. To do this, it is important to determine the degree of soil salinity in the wash area, the name and grade of the plant, the composition of the salts and the change in crop yields after leaching operations. As a consequence, analyzing the change in crop yields, the optimal solution for land leaching is selected. The optimal solution for land leaching is determined by the formula of Volobuyev[11;12;13;14].

\[
N = \frac{\log c_0}{\log c_r} + \frac{\alpha}{\mu} h
\]  

1)

Here:
- \(c_0, c_r\)-content of salts before leaching and permissible norms, relative to gravity in% ratio.
- \(\alpha\)-coefficient of free salt supply.
- \(h\)-depth of the washed soil layer, m
- \(\mu\)-coefficient associated with the rate of removal of saline water.
Methods. Experiments were conducted in the Syrdarya, Surkhandarya and Bukhara regions in farms specializing in cotton growing (Fig.1). The soils in the experimental plots are mainly of a much more moderate degree of salinity, medium and light loam, mainly soils contain Cl, K, Na, and Mg salts. The middle-silt soils are 0.01-0.04 percent chlorine, the light loam is 0.04-0.10 percent chlorine ion[15;16;17;18].

Here, according to Volobuyev's formula, areas with the same fertility and area are selected, but with different degrees of salinity.

To carry out the experiment, the mechanical composition of the soil, the relief, the meliorative state, the types of soil and the hydromodule areas in these areas should be appropriate. At the same time, a soil map with a scale of 1: 10000 should be used to correctly evaluate the experimental plot. In the absence of a soil map, 2-3 pits are excavated for the morphological determination of the genetic layer. Together with this, a simultaneous 5-fold analysis of nitrogen, phosphorus, potassium and humus at a depth of 100-150 m

Here, the wash area of the degree of salinity (S) is determined before and after leaching using the Progress-IT device. The degree of salinity before flushing is determined by (S) FAO-16 Ese, dS / m, the depth of leaching (h) is 1 m, the salt supply index (a) is 0.97 ga, the indicator of used leaching water is assumed to be constant \( (H_{\text{wat}}) \) [19; 20].

Results and Discussions. A field experiment was conducted in 2012-2016 on the territory of the farm "Azamat tazhibakor" of Mirzaabad district of the Syrdarya...
The territory of the farm with an area of 39.5 hectares (cotton -26 hectares and corn 13.5 hectares) was divided into 5 sites for salt leaching operations with different leaching norms. As a reference option, the existing approach was chosen, in which the leaching rate is accepted the same, regardless of the type and crop resistance to salinization, the fields consist of soil with light loam.

The results of land fertility, salinity degree, plant species during the leaching of the experimental plot are shown in Fig. 2.

It can be seen from Fig. 2 that if the leaching norm is used taking into account the plant species, i.e. for the sowing of cotton, the flow of water is 4000 m$^3$/ha and for corn 2000 m$^3$/ha, in this case the yield of crops is not high. But, if you do not change the water consumption for land leaching in these areas, i.e. For the field with cotton planting to use 3000 m$^3$/ha and for corn 3000 m$^3$/ha, the relatively average crop yields increase.

The second experiment was conducted in the Surkhandarya region of the Kumkurgan district in the farm "Saodat". Here fields were chosen with a sowing area of cotton 10.8 hectares and corn in 13.2 hectares, mainly the fields consist of soil with heavy loam. Fig. 3.
Here, too, if we analyze the results, when using the leaching norm, taking into account the plant species, i.e. For the sowing of cotton, the water discharge is 4000 m³ / ha and for corn 2000 m³ / ha, then the yield of crops is not high. But, if you do not change the water consumption for land leaching in these areas, i.e. For the field with cotton planting to use 3250 m³/ha and for corn 3500 m³/ha, it is possible to achieve relatively positive crop yields.

The third experimental site was located in the Bukhara region in the Karakul district in the farm Chashma. Here the selected plot consisted of loam, the area of irrigated land for cotton is 8.8 hectares, for corn 3.6 hectares. Fig.3.
It can be seen from Fig. 4 that if the leaching norm is used taking into account the plant species, i.e. For the sowing of cotton, the flow of water is 4000 m$^3$/ha and for corn 2000 m$^3$/ha, in this case the yield of crops is not high. But, if you do not change the water consumption for land leaching in these areas, i.e. For the field with cotton planting to use 2500 m$^3$/ha and for corn 5500 m$^3$/ha, the relatively average crop yields increase.

Table 1 shows the influence of a variety of soils during leaching operations on yield and an increase in total income.

| Anexperience | Type of soil | Irrigated area, ha | The optimum leaching rate, m$^3$/ha | Yield, centner/ha | Total revenue (thousand sum) |
|--------------|--------------|-------------------|-------------------------------------|-----------------|----------------------------|
|              | Cotton | Corn | Cotton | Corn | Cotton | Corn | Cotton | Corn |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |

Syrdarya region Mirzaabaddistrict farm «Azamattajribakor»

| Recommend method | Light loam | 5,2 | 2,7 | 3000 | 3000 | 29,4 | 47,5 | 27,2 | 43,4 | 36354 |
|-----------------|-------------|-----|-----|-------|-------|------|------|------|------|--------|
| Control         | 5,2         | 5,2 | 4000 | 2000 | 30    | 27,8 | 27,2 | 43,4 |        |

Surkhandarya region of the Kumkurgandistrict farm «Saodat»

| Recommend method | Heavy loam | 10,8 | 13,2 | 3250 | 3750 | 30 | 70,5 | 28,5 | 61,6 | 63028 |
|-----------------|-------------|------|------|------|------|---|-----|------|------|--------|
| Control         | 10,8        | 13,2 | 4000 | 4000 | 30   | 53,3 | 28,5 | 61,6 |        |

Bukhara region Karakul district farm «Chashma»

| Recommend method | Loam | 8,8 | 3,6 | 2500 | 5500 | 30 | 63,1 | 28,8 | 56,3 | 98912 |
|-----------------|------|-----|-----|------|------|---|-----|------|------|--------|
| Control         | 8,8 | 3,6 | 4000 | 2000 | 30   | 42,8 | 28,8 | 56,3 |        |

Together with this, the leaching starts from the central strip of the reservoir, the tomondagylargaeon is approached, together with this the leaching begins from the beginning of the field part and ends in a decrease.

**Conclusions.** In addition, when calculating the technology of the leaching regime and the technology of their conduct, it is necessary to take into account the unevenness of the relief of saline lands. Such land should be washed with a high leaching rate.

In conclusion, the following can be cited:
- in the future, leaching on saline lands should be carried out taking into account the variety and name of plants;
- in order to reduce the volume of water during leaching operations, temporarily design and use drainage systems;
- uniform use of irrigation water from water intake facilities, supply of measuring devices, prevention and use of water-saving technologies in the AWS and in farms.
- use strictly according to agrotechnical rules in the permissible periods of plowing and deep loosening of the soil, leaching the land, watering and moistening the soil.
