Abstract

We investigate the asymptotic version of the Erdős-Ko-Rado theorem for the random \( k \)-uniform hypergraph \( H_k(n, p) \). For \( 2 \leq k(n) \leq n/2 \), let \( N = \binom{n}{k} \) and \( D = \binom{n-k}{k} \). We show that with probability tending to 1 as \( n \to \infty \), the largest intersecting subhypergraph of \( H_k(n, p) \) has size \( (1 + o(1)) \frac{p^k}{k} n N \), for any \( p \gg \frac{n}{k} \ln^2 \left( \frac{n}{k} \right) D^{-1} \). This lower bound on \( p \) is asymptotically best possible for \( k = \Theta(n) \). For this range of \( k \) and \( p \), we are able to show stability as well.

A different behavior occurs when \( k = o(n) \). In this case, the lower bound on \( p \) is almost optimal. Further, for the small interval \( D^{-1} \ll p \leq (n/k)^{1-\varepsilon} D^{-1} \), the largest intersecting subhypergraph of \( H_k(n, p) \) has size \( \Theta(\ln(pD)ND^{-1}) \), provided that \( k \gg \sqrt{n \ln n} \).

Together with previous work of Balogh, Bohman and Mubayi, these results settle the asymptotic size of the largest intersecting family in \( H_k(n, p) \), for essentially all values of \( p \) and \( k \).

1 Introduction

The Erdős-Ko-Rado theorem \cite{6} is a cornerstone in extremal combinatorics. Let \([n]\) denote the set \( \{1, 2, \ldots, n\} \), and \( \binom{[n]}{k} \) denote the set of all \( k \)-element subsets of \([n]\). A family of \( k \)-element sets \( F \subseteq \binom{[n]}{k} \) is called a \( k \)-uniform hypergraph with the vertex set \([n]\), and such a hypergraph is called intersecting if \( A \cap B \neq \emptyset \) holds for every edge \( A, B \in F \). The Erdős-Ko-Rado theorem then states that for \( 2 \leq k \leq n/2 \), an intersecting family \( F \subseteq \binom{[n]}{k} \) must satisfy \( |F| \leq \binom{k}{n} \). This is best possible, as seen by the principal hypergraphs \( F_i \), which consist of all edges containing the fixed element \( i \in [n] \).

We investigate a random analogue of the Erdős-Ko-Rado theorem in which the ambient space \( \binom{[n]}{k} \) in the theorem is replaced by a random space. Random analogues of extremal results have been studied extensively in the last decades, and we refer to \cite{18, 5, 4, 17} for the history of this line of research and recent breakthroughs.

The ambient random space we will work with is \( H_k(n, p) \), the binomial random \( k \)-uniform hypergraph on the vertex set \([n]\) in which each edge \( e \in \binom{[n]}{k} \) is included in \( H_k(n, p) \) independently with probability \( p \). Further, for a \( k \)-uniform \( H \), let \( i(H) \) denote size of the largest intersecting subhypergraph of \( H \), i.e., \( i(H) = \max\{|F|: F \subseteq H \text{ and } F \text{ is intersecting}\} \). In this notation the Erdős-Ko-Rado theorem states that \( i(H_k(n, 1)) = i \left( \binom{[n]}{k} \right) = \frac{k}{n} \binom{n}{k} \).
Notation. All asymptotic limits in this paper are taken as \( n \to \infty \). If we write \( a(n) \ll b(n) \) or \( a(n) = o(b(n)) \), it means that \( a(n)/b(n) \to 0 \). In particular, the notation \( o(1) \) represents a function that goes to 0 as \( n \to \infty \), as usual. For simplicity, we omit floor and ceiling functions, whenever they are not essential. We say that a sequence of events \( \mathcal{E}_n \) holds asymptotically almost surely if \( \Pr[\mathcal{E}_n] \to 1 \) as \( n \to \infty \).

We will be interested in \( i(\mathcal{H}_k(n, p)) \) for \( k = k(n) \) and all \( p = p(n) \in (0, 1) \). This question was investigated by Balogh, Bohman and Mubayi [3], which obtained very precise results on the size and on the structure of the largest intersecting family in \( \mathcal{H}_k(n, p) \), for \( k \leq n^{1/2-o(1)} \). For larger \( k \), they obtained asymptotic tight bounds on \( i(\mathcal{H}_k(n, p)) \), however, only for rather large values of \( p \). In general, their result highly depends on the range of \( k \) and \( p \), and hence it is slightly cumbersome to state. Therefore, we will only partially discuss it here, and refer to [3] for detailed information. Their result concerning the large range of \( k \) is given below in Proposition 1.1.

**Proposition 1.1** (Proposition 1.3 in [3]). Let \( \delta = \delta(n) > 0 \) and \( N = \binom{n}{k} \). If \( \ln n \ll k < (1-\delta)n/2 \) and \( p \gg (1/\delta)((\ln n)/k)^{1/2} \), then almost surely as \( n \to \infty \):

\[
i(\mathcal{H}_k(n, p)) = (1 + o(1))p(k/n)N.
\]

In other words, for this range of \( p \), the expected size of the intersection of a principal family \( \mathcal{F}_i \) with \( \mathcal{H}_k(n, p) \) is very close to the size of a maximum intersecting subfamily of \( \mathcal{H}_k(n, p) \). We extend this result, and provide an almost complete description of \( i(\mathcal{H}_k(n, p)) \) as follows.

**Theorem 1.2.** For all \( 0 < \varepsilon < 1 \) there exists a constant \( C > 0 \) for which the following holds. Let \( p = p(n) \in (0, 1) \), \( k = k(n) \), where \( 2 \leq k \leq n/2 \), \( N = \binom{n}{k} \), and \( D = \binom{n-k}{k} \). Then almost surely as \( n \to \infty \):

\[
\begin{align*}
(1) \ i(\mathcal{H}_k(n, p)) &= (1 \pm \varepsilon)pN & \text{if } N^{-1} \ll p \ll D^{-1}, \\
(2) \ i(\mathcal{H}_k(n, p)) &\geq (1-\varepsilon)\frac{N}{D} \ln(pD) & \text{if } D^{-1} \ll p \leq (n/k)D^{-1} \text{ and } k \gg \sqrt{n \ln n}, \\
(3) \ i(\mathcal{H}_k(n, p)) &\leq C\frac{N}{D} \ln(pD) & \text{if } D^{-1} \ll p \leq (n/k)^{1-\varepsilon}D^{-1}, \\
(4) \ i(\mathcal{H}_k(n, p)) &= (1 \pm \varepsilon)p_k^2N & \text{if } p \geq C(n/k) \ln^2(n/k)D^{-1}.
\end{align*}
\]

The first bound follows from a standard deletion argument, and we state it here for completeness. Note also that \( i(\mathcal{H}_k(n, p)) \) is monotone in \( p \), hence, in the range of \( p \) around \( (n/k)D^{-1} \) not mentioned in the theorem, we have \( i(\mathcal{H}_k(n, p)) = O((N/D) \ln^2(n/k)) \) due to (4).

If \( k \) is linear in \( n \), the bounds in (1) and (4) determine \( i(\mathcal{H}_k(n, p)) \) asymptotically for essentially all \( p \). Here, we have a change of behaviour around \( D^{-1} \). Roughly speaking, for \( p \) below \( D^{-1} \), essentially all of \( \mathcal{H}_k(n, p) \) is intersecting. Beyond that point, i.e. for \( p \gg D^{-1} \), the largest intersecting subhypergraph of \( \mathcal{H}_k(n, p) \) has size very close to the size of the intersection of a principal hypergraph with \( \mathcal{H}_k(n, p) \). Observe that cases (2) and (3) are trivial for \( k = \Theta(n) \).

For \( k = o(n) \) there is a rather short range of \( p \) where \( i(\mathcal{H}_k(n, p)) \) reveals a “flat” behaviour. Indeed, the upper bound (3) shows that \( i(\mathcal{H}_k(n, p)) \) grows slowly with \( p \), since it appears only in the \( \ln \)-term. The corresponding lower bound in (2) shows that for \( k \geq n^{1/2+\omega(1)} \) this bound is tight up to a multiplicative constant. We provide no lower bound for the range \( k < n^{1/2-o(1)} \) here, as in this case the result of Balogh et al. is more satisfactory. Again, we refer to [3] for further information.
Although the “flat range” phenomenon might come as a surprise, it has been observed elsewhere. Indeed, in the dense case, i.e. for \( p = 1 \), and for \( k = o(n) \), the size of the largest intersecting family is vanishing compared to the ambient space, that is, \( i\left(\binom{n}{k}\right) = \frac{k}{n}\binom{n}{k} = o\left(\binom{n}{k}\right) \). For these so called “degenerate” problems, the random analogues typically reveal such an intermediate flat behaviour, as observed for example in [13, 14].

The question of which range of \( p \) the largest intersecting family \( F \subset \mathcal{H}^k(n, p) \) is indeed the projection of a principal family has been successfully addressed in [3] for \( k < n^{1/2-o(1)} \). For larger \( k \), which we are mainly interested in, the problem seems to be more complicated, and has only been studied recently in [9], for constant \( p \). We make no contribution to this question here. However, besides the bounds on \( i(\mathcal{H}^k(n, p)) \), we are able to show stability for \( k = \Theta(n) \) in the same range for \( p \) as in case (4) in Theorem 1.2.

**Theorem 1.3.** For every \( \beta > 0 \) and \( \varepsilon > 0 \) there exist constants \( \delta > 0 \) and \( C > 0 \) for which the following holds. For any \( \varepsilon n < k(n) < (1/2 - \beta)n \) and \( p \geq C \cdot D^{-1} \), asymptotically almost surely stability holds, i.e., for every intersecting family \( F \subset \mathcal{H}^k(n, p) \) of size \( |F| \geq (1 - \delta)p(k/n)N \), there is an element \( i \in [n] \) that is contained in all but at most \( \varepsilon p(k/n)N \) elements of \( F \).

In the dense case, i.e. for \( p = 1 \), the result was proven by Friedgut [7]. Indeed, the proof of Theorem 1.3 relies on the result of Friedgut and on a removal lemma for the Kneser graph due to Friedgut and Regev [8]. Whether \( \mathcal{H}^k(n, p) \) satisfies stability for \( k = o(n) \) remains open.

**Further results and organization.** In proving Theorems 1.2 and 1.3 it will be convenient for us to work with the Kneser graph \( K(n, k) \). The vertex set of this graph is \( \binom{[n]}{k} \), and two \( k \)-element sets form an edge if and only if they are disjoint. Hence \( K(n, k) \) is a \( (n-k) \)-regular graph on \( \binom{n}{k} \) vertices, and a hypergraph \( F \subset \binom{[n]}{k} \) is intersecting if and only if \( F \) is an independent set in \( K(n, k) \). Further, let \( K(n, k, p) \) denote the subgraph of \( K(n, k) \) induced on the random vertex set obtained by including each vertex from \( \binom{[n]}{k} \) independently with probability \( p \). Due to the correspondence, all bounds on intersecting subgraphs of \( \mathcal{H}^k(n, p) \) will follow from corresponding bounds on the size of largest independent sets in \( K(n, k, p) \).

Using this translation, Theorem 1.2 follows from a more general scheme which relies on the technical Proposition 2.6 and Lemma 2.2, to be introduced in the next section. Further, for Theorem 1.3 we will need Lemma 2.5, which together with Lemma 2.2 will be proven in Section 3. Based on these results, we will give the proofs of Theorems 1.2 and 1.3 in Section 2.

In general, the proof scheme based on Proposition 2.6 and Lemma 2.2 can be used to bound the size of the largest independent sets in random subgraphs of any \( D \)-regular graph \( G \) (actually, a sequence of graphs). Here by random subgraph we mean the graph induced on a binomial random subset of the vertex set. This application yields asymptotically sharp bounds if \( G \) has an independent set of size (close to) \( -\lambda_{\min}[V(G)]/(D - \lambda_{\min}) \). Indeed, Theorem 1.2 shows such an application to the Kneser graph, and there are many other graphs for which this applies. We refer, e.g., to [2] for a list of such graphs which include the weak product of the complete graph, line graphs of regular graphs which contain a perfect matching, Paley graphs, some strongly regular graphs, and appropriate classes of random regular graphs (see Section 5.1. of [2]).

The proof of Proposition 2.6 will be given in Section 4. It is based on a description of all independent sets in locally dense graphs. This idea can be traced back to the work of Kleitman and Winston [12], and has been exploited in various contexts since their work. Though similar proofs have been given elsewhere, none of them seems to fully fit in our context. This also applies
to the powerful extension of the ideas of Kleitman and Winston to hypergraphs due to Balogh, Morris and Samotij in [4] (see also [17]), which only partially suits our needs.

2 Proofs of Theorems 1.2 and 1.3

As mentioned before, the proofs of the main theorems rely on Proposition 2.6. A central notion employed in this proposition which applies to $K(n, k)$ is the following.

**Definition 2.1.** Given $\lambda \in (0, 1]$, $\gamma \in (0, 1]$, and a graph $G$ on $N$ vertices, we say that $G$ is $(\lambda, \gamma)$-supersaturated if for any subset $S \subseteq V(G)$ with $|S| \geq \lambda N$, we have

$$e(S) \geq \gamma \left( \frac{|S|}{N} \right)^2 e(G).$$

In addition, let $\lambda = \lambda(n) > 0$ and $\gamma = \gamma(n) > 0$. A sequence $\{G_n\}_{n \in \mathbb{N}}$ is called $(\lambda(n), \gamma(n))$-supersaturated if $G_n$ is $(\lambda(n), \gamma(n))$-supersaturated for each $n \in \mathbb{N}$.

Hence, in a $(\lambda, \gamma)$-supersaturated graph $G$ each set $S$ of size at least $\lambda N$ spans many edges. Indeed, up to the multiplicative factor $\gamma$, $S$ spans as many edges as expected from a random subset of $V(G)$ of the same size.

Using an extension of Hoffman’s spectral bound [10], one can relate supersaturation to the eigenvalues of a graph. We refer to Section 3 for the proof.

**Lemma 2.2.** Let $G$ be a $D$-regular graph on $N$ vertices, and let $\lambda_{\min}$ denote the smallest eigenvalue of the adjacency matrix of $G$. Then every set $S \subset V(G)$ satisfies

$$e(S) \geq \left( \frac{\lambda_{\min} N}{D} + \frac{D - \lambda_{\min}}{D} \right) \left( \frac{|S|}{N} \right)^2 e(G).$$

As the eigenvalues of the Kneser graph are known due to Lovász [15], we immediately conclude the following supersaturation for the Kneser graph.

**Lemma 2.3.** Let $2 \leq k \leq n/2$ and $\tau = \tau(n) > 0$. Then $K(n, k)$ is $((1 + \tau)\frac{k}{n}, \frac{\tau}{1 + \tau})$-supersaturated.

**Proof.** The Kneser graph $K(n, k)$ has degree $D = (n-k)$, and the smallest eigenvalue of $K(n, k)$ is given by (see [15]):

$$\lambda_{\min} = -\left( \frac{n-k-1}{k-1} \right) = -\frac{k}{n-k}D.$$

Let $S \subset \binom{[n]}{k}$ be of size at least $(1 + \tau)\frac{k}{n}N$, with $N = \binom{n}{k}$. Lemma 2.2 implies that

$$e(S) \geq \left( -\frac{n}{(n-k)(1+\tau)} + \frac{n}{n-k} \right) \left( \frac{|S|}{N} \right)^2 e(G),$$

and the claim follows. \qed

Beyond the notion of supersaturation needed for the proof of Theorem 1.2, we will rely on the following notion of robust stability in the proof of Theorem 1.3 (see also [16]).
Definition 2.4. Let $\lambda, \varepsilon, \delta > 0$. Let $G$ be a graph on $N$ vertices, and let $\mathcal{B}(G) \subseteq \mathcal{P}(V(G))$ be a family of sets. We say that $G$ is $(\lambda, \mathcal{B}(G))$-stable with respect to $(\varepsilon, \delta)$ if for every $S \subseteq V(G)$ with $|S| \geq (1 - \delta)\lambda N$, we have either

- $e(S) \geq \delta \left( \frac{|S|}{N} \right)^2 e(G)$, or
- $|S \setminus B| \leq \varepsilon \lambda N$, for some $B \in \mathcal{B}(G)$.

In addition, let $\lambda = \lambda(n) > 0$, $\{G_n\}_{n \in \mathbb{N}}$ be a sequence of graphs, and $\mathcal{B} = \{\mathcal{B}_n\}_{n \in \mathbb{N}}$ with $\mathcal{B}_n \subseteq \mathcal{P}(V(G_n))$ be a sequence of families of sets. We say that $\{G_n\}_{n \in \mathbb{N}}$ is $(\lambda, \mathcal{B})$-stable if for any $\varepsilon > 0$ there exists $\delta > 0$ and $n_0 \in \mathbb{N}$ such that for all $n \geq n_0$, the graph $G_n$ is $(\lambda(n), \mathcal{B}_n)$-stable with respect to $(\varepsilon, \delta)$.

It is instructive to think of $\mathcal{B}(G)$ as the family of largest independent sets in $G$, and of $\lambda N$ as the size of each $B \in \mathcal{B}$. The first part of the definition roughly says that if $G$ is robustly stable, then any vertex set $S$ whose size is close to the size of a largest independent set in $G$ must either contain many edges, or be close to a largest independent set in structure.

The Kneser graph satisfies robust stability for $k$ linear in $n$, as stated in the next lemma. It is a direct consequence of the corresponding stability result proven by Friedgut [7], and the removal lemma proven by Friedgut and Regev [8]. Again, we refer to Section 3 for the details of the proof. In the following, let $\mathcal{F}_i \subseteq \left[ \begin{pmatrix} n! \end{pmatrix} \right]_k$ denote the principal hypergraph centered at $i$, i.e., the hypergraph consisting of all $k$-element subsets of $[n]$ containing $i \in [n]$.

Lemma 2.5. Let $\beta > 0$ and $k = k(n)$, where $\beta n \leq k \leq (1/2 - \beta)n$, and let $G_n = K(n, k)$. Further, let $\mathcal{B}_n(G_n) = \{\mathcal{F}_i \mid i \in [n]\} \subset \mathcal{P}(V(G_n))$, and set $\mathcal{B} = \{\mathcal{B}_n\}_{n \in \mathbb{N}}$. Then $G = \{G_n\}_{n \in \mathbb{N}}$ is $(k/n, \mathcal{B})$-stable.

With supersaturation and robust stability defined, we are now ready to state our main technical result. Given a graph $H$, we use $\alpha(H)$ to denote the size of the largest independent set in $H$. Also, for a finite set $V$, we let $V_p$ be a random subset of $V$ obtained by selecting each element $v \in V$ independently with probability $p$.

Proposition 2.6. Let $\lambda = \lambda(n)$ and $\gamma = \gamma(n)$ be $(0, 1)$-valued functions, and let $G = \{G_n\}_{n \in \mathbb{N}}$ be a family of graphs, where each $G_n$ has $N = N(n)$ vertices (with $\lim_{n \to \infty} N(n) = \infty$) and average degree $D = D(n)$. For any constant $\varepsilon > 0$ there exist constants $C = C(\varepsilon) > 0$ and $\delta = \delta(\varepsilon) > 0$ such that for any probability sequence $p = p(n) \in (0, 1]$, the following holds. For a random spanning subgraph $H_n = G_n[V_p]$, where $V = V(G_n)$, we have:

(i) If $N^{-1} \ll p \ll D^{-1}$, then $\alpha(H_n) = (1 + \varepsilon)pN$ asymptotic almost surely.

(ii) If $G$ is $(\lambda, \gamma)$-supersaturated and $9D^{-1} \leq p \leq \lambda^6(\varepsilon \gamma D)^{-1}$, then

$$\mathbb{P}\left( \alpha(H_n) > \frac{4N}{\varepsilon \gamma D} \ln(pD) \right) \leq \exp\left\{ -\frac{N}{\gamma D} \ln(pD) \right\}.$$  

(iii) If $G$ is $(\lambda, \gamma)$-supersaturated and $p \geq C(\varepsilon \gamma D)^{-1} \ln^2(\varepsilon / \lambda)$, then

$$\mathbb{P}\left( \alpha(H_n) \geq (1 + \varepsilon)\lambda pN \right) \leq \exp\{ -\varepsilon^2 p \lambda N / 24 \}.$$
(iv) If \( G \) is \((\lambda, B)\)-stable and \( p \geq C(\lambda D)^{-1} \ln^2(e/\lambda) \), then with probability at least \( 1 - \exp(-\delta^2 \lambda p N / 2) \), the following holds: every independent set \( I \) in \( H_n \) of size at least \((1 - \delta) \lambda p N \) satisfies \( |I \setminus B| \leq \varepsilon \lambda p N \) for some \( B \in \mathcal{B}_n \).

In addition, the following result will be needed for the lower bound (2) in Theorem 1.2. It is Shearer’s extension [19] of a result due to Ajtai, Komlós and Szemerédi [1].

**Proposition 2.7** ([1], [19]). Let \( G = \{G_n\}_{n \in \mathbb{N}} \) be a sequence of graphs on \( N = N(n) \) vertices with average degree at most \( D = D(n) > 1 \). If each \( G_n \) is triangle-free, then \( G_n \) contains an independent set of size \( N(D \ln D - D + 1)/(D - 1)^2 \geq N(-1 + \ln D)/D \).

Finally, we shall repeatedly use Chernoff’s bound for binomial random variables, which we state here for reference (see [11] Theorem 2.1).

**Lemma 2.8.** Given integers \( m, s > 0 \) and \( \zeta \in [0, 1] \), we have:

\[
\Pr(\text{Bin}(m, \zeta) \geq m\zeta + s) \leq e^{-s^2/(2\zeta m + s/3)}.
\]

\[
\Pr(\text{Bin}(m, \zeta) \leq m\zeta - s) \leq e^{-s^2/(2\zeta m)}.
\]

We are now ready to present the proofs of Theorems 1.2 and 1.3.

**Proof of Theorem 1.2**. Given \( 0 < \varepsilon < 1 \), apply Proposition 2.6 with \( \varepsilon/4 \) in order to obtain a corresponding constant \( C_1 \). Let \( C = \max\{32/\varepsilon^2, 32C_1/\varepsilon\} \). Further, let \( k = k(n) \), and \( G_n = K(n, k) \). Recall that \( G_n \) is a \( D \)-regular graph on \( N \) vertices, with \( D = D(n) = \binom{n-k}{k} \) and \( N = N(n) = \binom{n}{k} \). Let \( H_n = G_n[V_p] \), where \( V = V(G_n) \), and \( V_p \) is the set obtained by including each vertex of \( V \) independently with probability \( p \). We apply Proposition 2.6 to \( \{G_n\}_{n \in \mathbb{N}} \), with functions \( N(n) \) and \( D(n) \) as defined above. The first bound of Theorem 1.2 follows immediately from the first case of Proposition 2.6.

For the third and fourth bounds of Theorem 1.2, note that by Lemma 2.3 applied with \( \tau = \varepsilon/2 \), we know that \( G_n \) is \((\lambda, \gamma)\)-supersaturated, with \( \lambda \leq (1 + \varepsilon/2)k/n \) and \( \gamma = \varepsilon/4 \). Assume that \( k = o(n) \), since for \( k \) linear in \( n \) this range of \( p \) is trivial. By the second part of Proposition 2.6 applied with \( \varepsilon_1 = \varepsilon/2 \), we derive that for \( 9D^{-1} \leq p \leq (n/k)^{1-\varepsilon/2}(\varepsilon D)^{-1} \), which contains our interval for \( p \) in the third case, with probability at least \( 1 - \exp(-4N\ln(pD)/(\varepsilon D)) \), we have

\[
i(H^k(n, p)) < \frac{8N}{\varepsilon^2 D} \ln(pD) \leq C \frac{N}{D} \ln(pD).
\]

As \( p \gg D^{-1} \), this probability tends to one as \( n \) goes to infinity, which gives the upper bound in the third case.

Next we show the fourth bound of Theorem 1.2. The lower bound follows by considering the subhypergraph of \( H^k(n, p) \) consisting of all hyperedges containing, say, the element \( n \). Using the Chernoff bound (Lemma 2.8), we have with high probability that this (intersecting) subhypergraph has size at least \((1 - \varepsilon)p(k/n)N \). For the upper bound, we apply the third bound of Proposition 2.6 with \( \varepsilon/4 \) and \( \lambda, \gamma \) as chosen above. Then, by the choice of \( C \), we have \( i(H^k(n, p)) \leq (1 + \varepsilon)\frac{1}{n} \ln(pN) \) for \( p \geq C(n/k)D^{-1} \ln^2(n/k) \geq C_1(\lambda \gamma D)^{-1} \ln^2(e/\lambda) \), and the claim follows.

Finally, we prove the second bound of Theorem 1.2. Observe that this range of \( p \) is nontrivial only if \( k \ll n \). By Chernoff’s bound, almost surely \( H_n \) has at least \((1 - \varepsilon/32)pN \) vertices. Further,
\( \mathbb{E}[e(H_n)] = p^2 ND/2 \), and it is not hard to see that \( \text{Var}[e(H_n)] \leq 2p^3 N^2 D + p^2 ND \). By Chebyshev’s inequality, we derive

\[
\mathbb{P}\left( |e(H_n) - \mathbb{E}(e(H_n))| \geq \varepsilon p^2 ND/32 \right) \leq \frac{32^2 \text{Var}(e(H_n))}{\varepsilon^2 p^4 N^2 D^2}
\]

which goes to zero by the choice of \( p \).

**Claim 2.9.** For \( (n \ln n)^{1/2} \ll k \ll n \) and \( p \leq (n/k)D^{-1} \), asymptotically almost surely the number of triangles in \( H_n \) is at most \( \varepsilon p N/32 \).

**Proof.** The expected number of triangles in \( H_n \) is at most \( p^3 (n \choose k)^{(n-k) \choose (n-2k)} \). Using Markov’s inequality and \( p \leq (n/k)D^{-1} \), the claim follows if we can show that \( (n/k)^2 (n-k) \ll (n-2k) \). Indeed,

\[
\left( \frac{n-k}{k} \right) \left( \frac{n-2k}{k} \right)^{-1} = \frac{(n-k) \ldots (n-2k+1)}{(n-2k) \ldots (n-3k+1)} \geq \left( \frac{n-k}{n-2k} \right)^k \geq \left( 1 + \frac{k}{n} \right)^k,
\]

and using \( (1+x) \geq \exp\{x-x^2\} \) for \( 0 < x < 1 \), we obtain together with our assumption \( (n \ln n)^{1/2} \ll k \ll n \) that

\[
\left( \frac{n-k}{k} \right) \left( \frac{n-2k}{k} \right)^{-1} \geq \exp\{k^2/n - k^3/n^2\} \gg (n/k)^2,
\]

which completes the proof of the claim.

Hence, by removing at most \( \varepsilon p N/32 \) vertices, we obtain a triangle free graph with at least \( (1 - \varepsilon/16)pN \) vertices, and no more than \( (1/2 + \varepsilon/32)p^2 ND \) edges. Consequently, this graph has average degree at most \( (1 + \varepsilon/4)pD \), and due to Proposition 2.7 it contains an independent set of size

\[
\frac{(1 - \varepsilon/16)pN}{(1 + \varepsilon/4)pD} \left( \ln((1 + \varepsilon/4)pD) - 1 \right) \geq \frac{N}{D} \ln pD.
\]

This completes the proof.

**Proof of Theorem 1.3.** Let \( \beta > 0 \) be fixed, and \( \beta n \leq k \leq (1/2 - \beta)n \). Again, let \( G_n \) denote the Kneser graph \( K(n, k) \). Set \( \lambda = k/n \), and for a given \( n \), let \( \mathcal{B}_n \) be the set of all principal hypergraphs \( \mathcal{F}_i \), for \( i = 1, \ldots, n \). By Lemma 2.5, the family \( G = \{G_n\} \) is \((\lambda, \mathcal{B})\)-stable, where \( \mathcal{B} = \{\mathcal{B}_n\}_{n \in \mathbb{N}} \). For a given \( \varepsilon > 0 \), we apply Proposition 2.9 in order to obtain constants \( C' \) and \( \delta' > 0 \). Since \( k = \Theta(n) \), it is possible to choose appropriate constants \( C \) and \( \delta \) satisfying the conclusion of the theorem, which completes the proof.

### 3 Proofs of Lemmas 2.2 and 2.5

As mentioned before, the proof of Lemma 2.2 is a straightforward extension of Hoffman’s bound [10].

**Proof of Lemma 2.2.** Given a \( D \)-regular \( G \) with \( N \) vertices and smallest eigenvalue \( \lambda_{\text{min}} \), we need to show that for every non-empty \( S \subset V(G) \),

\[
e_S = e(S) \geq \left( \frac{\lambda_{\text{min}} N}{D} \frac{|S|}{|S|} + \frac{D - \lambda_{\text{min}}}{D} \right) \left( \frac{|S|}{N} \right)^2 e(G).
\]

7
Let $M$ denote the adjacency matrix of $G$. For $x, y \in \mathbb{R}^N$, let $\langle x, y \rangle = \sum_{i=1}^{N} x_i y_i$. Also, let $v_S$ be the 0/1-characteristic vector of $S$. First note that $\langle v_S, M v_S \rangle = 2 e_S$. Since $M$ is a symmetric real matrix, it is diagonalizable by an orthonormal basis. Let $u_1, \ldots, u_N$ be normalized eigenvectors of $M$ with corresponding eigenvalues $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_N = \lambda_{\min}$, respectively. Since $G$ is a D-regular graph, we have $u_1 = (1/\sqrt{N}, \ldots, 1/\sqrt{N})$ and $\lambda_1 = D$. Let $v_S = \sum_{i=1}^{N} a_i u_i$ be the expansion of $v_S$ by eigenvectors. We have

$$2e_S = \langle v_S, M v_S \rangle = \sum_{i=1}^{N} \lambda_i a_i^2 \geq \lambda_1 a_1^2 + \lambda_{\min} \sum_{i=2}^{N} a_i^2.$$ 

Now observe that $a_1 = \langle v_S, u_1 \rangle = \sqrt{N}$. In addition, $|S| = \langle v_S, v_S \rangle = \sum_{i=1}^{N} a_i^2$. Therefore,

$$2e_S \geq D \frac{|S|^2}{N} + \lambda_{\min} \left( |S| - \frac{|S|^2}{N} \right) = |S| \left( \lambda_{\min} + \frac{|S|}{N} (D - \lambda_{\min}) \right) = \left( \frac{|S|}{N} \right)^2 \frac{e(G)}{2} \left( \frac{\lambda_{\min} N}{D} \right) + \left( 1 - \frac{\lambda_{\min} N}{D} \right),$$

and the lemma follows. \qed

We now proceed to show robust stability for the Kneser graph for $k = \Omega(n)$. The proof is a direct consequence of stability due to Friedgut [7] and a removal lemma for the Kneser graph due to Friedgut and Regev [8], which we state next.

**Proposition 3.1** (Friedgut [7]). Given $\beta > 0$, let $k = k(n)$ be a sequence of integers satisfying $\beta n \leq k \leq (1/2 - \beta)n$. For all $\epsilon > 0$ there exists $\delta > 0$ and $n_0$ such that, for all $n \geq n_0$, the following holds. If $F \subseteq \binom{[n]}{k}$ is an intersecting family of size at least $(1 - \delta) \binom{n-1}{k-1}$, then there is $i \in [n]$ such that $|F \setminus F_i| \leq \epsilon \binom{n-1}{k-1}$.

**Proposition 3.2** (Friedgut and Regev [8]). Given $\beta > 0$, let $k = k(n)$ be a sequence of integers satisfying $\beta n \leq k \leq (1/2 - \beta)n$. Moreover, let $N = \binom{n}{k}$ and $D = \binom{n-1}{k-1}$. For all $\epsilon > 0$ there exists $\delta > 0$ and $n_0$ such that, for all $n \geq n_0$, the following holds. Every family $F \subseteq \binom{[n]}{k}$ which spans at most $\delta |F|^2 (D/N)$ non-intersecting pairs can be made intersecting by removing at most $\epsilon \binom{n-1}{k-1}$ elements from $F$.

**Proof of Lemma 2.5**. Given any $\epsilon > 0$, first let $\epsilon_2 = \epsilon/2$, and apply Proposition 3.2 to get a corresponding $\delta_2 = \delta_2(\epsilon_2) > 0$. Now set $\epsilon_1 = \min(\epsilon/2, \delta_2/2)$, and use this time Proposition 3.1 in order to obtain an appropriate $\delta_1 = \delta_1(\epsilon_1) > 0$. Finally, set $\delta = \min(\delta_1, \delta_2/2) = \delta(\epsilon) > 0$.

It follows that for any family $F$ with $|F| \geq (1 - \delta) \binom{n-1}{k-1}$ and $e(F) \leq \delta |F|^2 (D/N)$ there exists an intersecting family $F' \subseteq F$ obtained from $F$ by removing at most $\epsilon_1 \binom{n-1}{k-1}$ of its elements such that

$$|F'| \geq (1 - \delta - \epsilon_1) \binom{n-1}{k-1} \geq (1 - \delta_2) \binom{n-1}{k-1}.$$ 

In addition, Proposition 3.1 implies that for some $i \in [n]$, we have $|F' \setminus F_i| \leq \epsilon_2 \binom{n-1}{k-1}$. Therefore,

$$|F \setminus F_i| \leq |F \setminus F| + |F' \setminus F_i| \leq \epsilon_1 \binom{n-1}{k-1} + \epsilon_2 \binom{n-1}{k-1} \leq \epsilon \binom{n-1}{k-1},$$

which completes the proof. \qed
4 Proof of Proposition 2.6

We begin with the proof of a simple structural result for independent sets in graphs (Lemma 4.1). As mentioned before, similar proofs have been given elsewhere (see e.g. [14]). For a given graph $G$, let $\mathcal{I}_G(t)$ denote the set of independent sets of $G$ of size exactly $t$, and $\mathcal{I}_F$ denote the set of all independent sets in $G$.

**Lemma 4.1.** Let $G$ be a graph on $N$ vertices, and $\gamma > 0$ be an arbitrary real number. In addition, let $0 < \ell < t$ be integers. Then, for every independent set $I \subseteq V(G)$ of size at least $t$, there is a sequence of vertices $x_1, \ldots, x_\ell \in I$ and a sequence of subsets $V(G) \supseteq X_1 \supseteq \cdots \supseteq X_\ell$ depending only on $x_1, \ldots, x_\ell$ such that:

- $x_1, \ldots, x_i \not\subseteq X_i$ for all $i \leq \ell$,
- $I \setminus \{x_1, \ldots, x_i\} \subseteq X_i$ for all $i \leq \ell$.

Moreover, we have either

(i) $|X_i| \leq \left(1 - 2\gamma \frac{e(G)}{N^2}\right)|X_{i-1}|$ for all $1 \leq i \leq \ell$, or

(ii) $e(G[X_i]) < \gamma \frac{|X_i|^2}{N^2}e(G)$ for some $1 \leq i \leq \ell$.

**Proof.** Fix an independent set $I \in \mathcal{I}_G(t)$. We need to define the required sequences $x_1, \ldots, x_\ell$ and $X_1, \ldots, X_\ell$. Assume that we have already chosen elements $x_1, \ldots, x_{i-1} \in I$ and sets $V(G) = X_0 \supseteq X_1 \supseteq \cdots \supseteq X_{i-1}$ satisfying the conditions of our result. Observe that initially no element has been selected, and for convenience we set $X_0 = V(G)$.

Consider an ordering $(v_1, \ldots, v_{|X_{i-1}|})$ of the vertices in $X_{i-1}$ which satisfies

$$|N(v_i) \cap \{v_{i+1}, \ldots, v_{|X_{i-1}|}\}| \geq |N(v_j) \cap \{v_{i+1}, \ldots, v_{|X_{i-1}|}\}|$$

for all $i < |X_{i-1}|$ and all $j > i$. Such an ordering clearly exists, since one can repeatedly choose (and remove) the vertex with highest degree in the remaining graph. In this case we say that this is a max-ordering of the elements in $X_{i-1}$.

Let $j$ be the smallest index such that the vertex $v_j$ in the max-ordering of $X_{i-1}$ is contained in $I$. Such index must exist, since $I \setminus \{x_1, \ldots, x_{i-1}\} \subseteq X_{i-1}$ and $i - 1 < \ell < |I| = t$. We define $x_i = v_j$, and set $S = X_{i-1} \setminus \{v_1, \ldots, v_j\}$.

If $\deg(v_j, S) < 2\gamma |S|e(G)/N^2$ then we let $X_i = S$. Note that, due to the max-ordering and the definition of $v_j$, the number of edges in $X_i$ satisfies $e(X_i) < \gamma |X_i|^2e(G)/N^2$. Otherwise, i.e. for the case $\deg(v_j, S) \geq 2\gamma |S|e(G)/N^2$, we let $X_i = S \setminus N(v_j)$. Then,

$$|X_i| \leq |S| - \deg(v_j, S) = \left(1 - 2\gamma \frac{e(G)}{N^2}\right)|S| \leq \left(1 - 2\gamma \frac{e(G)}{N^2}\right)|X_{i-1}|.$$

Finally, observe that it follows from the definition of $v_j$ that we always have $I \setminus \{x_1, \ldots, x_i\} \subseteq X_i$, which completes the proof.

From this lemma we immediately deduce the following corollaries.
Corollary 4.2. Let $G = (V, E)$ be a fixed $(\lambda, \gamma)$-supersaturated graph on $N$ vertices with average degree $D$, where $\lambda, \gamma > 0$. Let $t \geq 1$, and $\ell$ be an integer such that $0 < \ell < t$. Finally, set

$$\nu = \nu(\ell) = \max \left\{ \left(1 - \gamma \frac{D}{N}\right)^\ell, \lambda \right\}.$$ 

Then, for every independent set $I \in \mathcal{I}_G(t)$, there exists a subset $L \subset I$ of size $\ell$ and a set $P(L)$, depending only on $L$, of size at most $\nu N$ such that $I \setminus L \subset P(L) \subset V(G)$. Further, we have $L \cap P(L) = \emptyset$. In particular, it follows that $|\mathcal{I}_G(t)| \leq (N^{\nu})^{(t-\ell)}$.

Proof. Given $I \in \mathcal{I}_G(t)$, we apply Lemma 4.1 to obtain a sequence of vertices $x_1, \ldots, x_\ell$ and sets $V = X_0, X_1, \ldots, X_\ell$, as stated. Now set $L = \{x_1, \ldots, x_\ell\}$ and $P(L) = X_\ell$, and observe that $I \setminus L \subset P(L)$ and $L \cap P(L) = \emptyset$.

If $|X_i| \leq \left(1 - 2\gamma \frac{e(G)}{N}\right)|X_{i-1}|$ for all $i \leq \ell$, then $|P(L)| \leq \left(1 - 2\gamma \frac{e(G)}{N}\right)^\ell N$. In other words, $|P(L)| \leq \left(1 - \gamma \frac{1}{N}\right)^\ell N$. On the other hand, if $e(X_i) < \gamma \frac{|X_{i}|^2}{N}e(G)$ for some $i \leq \ell$, then $|P(L)| \leq \lambda N$, since by assumption $G$ is $(\lambda, \gamma)$-supersaturated. Altogether, it follows that $|P(L)| \leq \nu N$, which completes the proof.

Corollary 4.3. Let $\lambda, \varepsilon, \delta > 0$ and $G = (V, E)$ be a graph on $N$ vertices which is $(\lambda, \mathcal{B})$-stable with respect to $(\varepsilon, \delta)$. Let $t > \ell = \ln \left(\frac{1}{\lambda}\right) N^2 \frac{\varepsilon}{2\delta e(G)}$. Then, for every independent set $I \in \mathcal{I}_G(t)$, there exists a subset $L \subset I$ of size $\ell$ and a set $P(L) \subset V(G)$ depending only on $L$ such that $I \setminus L \subset P(L)$ and $L \cap P(L) = \emptyset$. Furthermore, either

- $|P(L)| \leq (1 - \delta)\lambda N$, or
- $|P(L) \setminus B| \leq \varepsilon \lambda N$ for some $B \in \mathcal{B}$.

Proof. We apply Lemma 4.1 to $G$ using $\gamma = \delta$ in order to obtain a sequence of vertices $x_1, \ldots, x_\ell$ and subsets $X_1, \ldots, X_\ell$ with the desired properties. Let $L = \{x_1, \ldots, x_\ell\}$. If $|X_i| \leq \left(1 - 2\delta \frac{e(G)}{N}\right)|X_{i-1}|$ for all $i \leq \ell$, then set $P(L) = X_\ell$. Using our assumption on $\ell$, we get $|P(L)| \leq \left(1 - 2\delta \frac{e(G)}{N}\right)^\ell N \leq (1 - \delta)\lambda N$. Otherwise, pick the smallest index $j \leq \ell$ such that $e(G[X_j]) < \delta \frac{|X_j|^2}{N}e(G)$, and let $P(L) = X_j$. Again, if $|P(L)| \leq (1 - \delta)\lambda N$ we are done. On the other hand, if this condition does not hold we deduce from the $(\lambda, \mathcal{B})$-stability of $G$ that there exists some $B \in \mathcal{B}$ for which $|P(L) \setminus B| \leq \varepsilon \lambda N$, which completes the proof.

Now that we have all the necessary machinery, we proceed with the proof of Proposition 2.6.

Proof of Proposition 2.6 Let $\lambda = \lambda(n)$, $\gamma = \gamma(n)$, and $G = \{G_n\}_{n \in \mathbb{N}}$ be a sequence of graphs. For a given $0 < \varepsilon < 1$, let $C_1 = 800/\varepsilon^3$. For the proof of case (iv) in Proposition 2.6, suppose that $G$ is $(\lambda, \mathcal{B})$-stable for some $\mathcal{B}$. Then for $\varepsilon' = \varepsilon/2$, there is a constant $\delta' > 0$ and $n_1 \in \mathbb{N}$ such that, for all $n \geq n_1$, the graph $G_n$ is $(\lambda, \mathcal{B}_n)$-stable with respect to $(\varepsilon', \delta')$. We choose $\delta = \min\{\delta'/4, \varepsilon'/4, 1/16\}$ and $C_2 = 100/\delta^4$. Finally, set $C = \max\{C_1, C_2\}$, and let $n_0 \geq n_1$ be sufficiently large.

We proceed with the proof of the first case of Proposition 2.6. Assume that $N^{-1} \ll p \ll D^{-1}$. Using the Chernoff bound (Lemma 2.8), we have almost surely $|V_p| = (1 \pm \varepsilon/2)pN$, which proves the upper bound. Further, we have $\mathbb{E}(e(H_n)) = \frac{1}{2}NDp^2$ and by Markov’s inequality a.a.s. $e(H_n) \leq \frac{1}{2}NDp^2$. 

\[\Box\]
\( \varepsilon pN/2 \) holds. By deleting at most this number of vertices from \( H_n \), we obtain an independent set of size at least \((1 - \varepsilon)pN\), which proves the lower bound.

For the second part, assume that \( 9D^{-1} \leq p \leq \lambda^2 (\lambda \gamma D)^{-1} \). Further, let \( \ell = (1 + \varepsilon)N \ln(pD) > 0 \), and \( t = \frac{4N}{\varepsilon^2 D} \ln(pD) \). Let \( X \) be the random variable counting the number of independent sets of size exactly \( t \) in \( H_n \), i.e., \( X = |\mathcal{I}_{H_n}(t)| \). By the choice of our parameters, Corollary 4.2 applies, and we obtain:

\[
E[X] \leq \left( \frac{N}{\ell} \right) \left( \nu(\ell)N \right)^{t-\ell},
\]

where \( \nu(\ell) = \max \left\{ (1 - \gamma^2 N)^{\ell}, \lambda \right\} \). Using \( \binom{n}{k} \leq \left( \frac{en}{k} \right)^k \) and the choice of \( \ell \) and \( t \), we get

\[
\binom{N}{\ell} \leq \left( \frac{e^D}{\ln(pD)} \right)^{\ell} \quad \text{and} \quad \frac{\nu(\ell)N}{t-\ell} \leq \left( \frac{e^D \gamma D}{\ln(pD)} \right)^{t-\ell}.
\]

Combining both inequalities, and noting that our choice of \( C \) guarantees that \( \ell \leq \varepsilon t/2 \), we get:

\[
E[X] \leq \left( \frac{e^D pD \nu^{1-\varepsilon/2}}{\ln(pD)} \right)^t.
\]

In case \( \nu(\ell) = \lambda \), we have \( \gamma p D \nu^{1-\varepsilon/2} \leq \lambda^2 \leq 1 \), since \( p \leq \lambda^2 (\lambda \gamma D)^{-1} \). On the other hand, if \( \nu(\ell) \leq e^{-\ell^2 / 2} \), we have \( \gamma p D \nu^{1-\varepsilon/2} \leq \gamma \leq 1 \). Hence, \( E(X) \leq (e/\ln(pD))^t \), and the claim follows from Markov’s inequality.

For the third part, assume that \( p \geq C (\lambda \gamma D)^{-1} \ln^2 \left( \frac{\ell}{\lambda} \right) \). Let \( t = (1 + \varepsilon)p \lambda N \), and \( \ell = \frac{N}{\gamma D} \ln \left( \frac{\ell}{\lambda} \right) \).

We need to upper bound the following probability:

\[
q = \mathbb{P}[\exists I \subset V_p, |I| = t, I \text{ is an independent set in } G_n].
\]

It follows from Corollary 4.3 that for any \( I \in \mathcal{I}_{G_n}(t) \), there exist \( L \subset I \) of size \( \ell \) and \( P(L) \) such that \( I \setminus L \subset P(L) \subset V \). Therefore,

\[
q \leq \sum_L \mathbb{P}[L \subset V_p \text{ and } |V_p \cap P(L)| \geq t-\ell],
\]

where the sum is taken over all subsets \( L \in \binom{I}{\ell} \) that correspond to some independent as given by Corollary 4.3. Using the fact that \( L \) and \( P(L) \) are disjoint, we obtain

\[
q \leq \sum_L \mathbb{P}[L \subset V_p] \cdot \mathbb{P}[|V_p \cap P(L)| \geq t-\ell]. \tag{3}
\]

In addition, by our choice of \( \ell \), it follows that \( \nu(\ell) = \lambda \). Therefore, for any such \( L \), we have \( |P(L)| \leq \nu(\ell)N \leq \lambda N \). Further, the choice of \( \ell \) and \( p \) implies that \( \ell \leq (\varepsilon/2)p \lambda N \). Hence with \( X = |V_p \cap P(L)| \), we have due to the Chernoff bound that

\[
\mathbb{P}(X \geq t-\ell) \leq \mathbb{P} \left( X \geq p|P(L)| + \frac{\varepsilon p \lambda N}{2} \right) \leq \exp \left( -\frac{\varepsilon^2 p \lambda N}{12} \right).
\]
From \( \binom{N}{\ell} \leq \left( \frac{eN}{\ell} \right)^\ell \), it follows that:

\[
q \leq \left( \frac{eNp}{\ell} \right)^\ell \exp \left( -\frac{\varepsilon^2 p \lambda N}{12} \right) = \exp \left( \ell \cdot \ln \left( \frac{eNp}{\ell} \right) - \frac{\varepsilon^2 p \lambda N}{12} \right).
\]

By the choice of \( \ell \) it is now sufficient to show that

\[
\frac{24}{\varepsilon^2 \gamma \lambda D} \ln(e/\lambda) \leq \frac{p}{\ln \left( \frac{eNp}{\ell} \right)}.
\]

As the left hand side is independent of \( p \), and the right hand side is increasing in \( p \), it is sufficient to show the inequality for \( p = C(\lambda \gamma D)^{-1} \ln^2(e/\lambda) \). In this case the inequality follows from \( 24/\varepsilon^2 \leq C \ln(e/\lambda)/\ln \left( \frac{eN}{\ell} \ln(e/\lambda) \right) \). Since \( eC/\lambda > \ln(e/\lambda) \), this follows from \( 48/\varepsilon^2 \leq C \ln(e/\lambda)/(\ln(e/\lambda) + \ln C) \), which holds due to our choice of \( C_1 \) and \( C \).

For the last part, let \( p \geq C(\lambda D)^{-1} \ln^2(e/\lambda) \). Further, let

\[ T = \{ I \in \mathcal{I}_G : |I| > (1 - \delta)\lambda p N \text{ and } |I \setminus B| > \varepsilon \lambda p N \text{ for all } B \in \mathcal{B}_n \}. \]

Our task is to upper bound the value of

\[ q_T = \mathbb{P}(\text{There is an independent set } I \subset V_p \text{ with } I \in T). \]

Recall our choice of \( \varepsilon' \), \( \delta' \), and \( n_0 \), and that \( G_n \) is \((\lambda, \mathcal{B}_n)\)-stable with respect to \((\varepsilon', \delta')\) for every \( n \geq n_0 \). We apply Corollary 4.3 with \( \varepsilon', \delta', t = (1 - 4\delta')\lambda p N \), and \( \ell = \frac{N}{\delta' D} \ln \frac{e}{\lambda} \leq \delta \lambda p N \). This implies that for every \( I \in T \) there is some \( L = L(I) \) of size \( \ell \) and some \( P(L) \subset V(G_n) \) (which depends only on \( L \) disjoint from \( L \) such that \( I \setminus L \subset P(L) \). Hence, if there is an \( I \subset V_p \) with \( I \in T \), then there is an \( L \) of size \( \ell \) such that

(A) \( L \subset V_p \), and

(B) \(|P(L) \cap V_p| \geq (1 - \delta)p \lambda N - \ell \geq (1 - 2\delta)p \lambda N \text{ and } |(P(L) \setminus B) \cap V_p| > \varepsilon \lambda p N \text{ for all } B \in \mathcal{B}_n \).

Let \( q_{P(L)} \) is the probability that event (B) holds. As \( L \) and \( P(L) \) are disjoint, we have

\[
q_T \leq \sum_L \mathbb{P}[L \subset V_p] \cdot q_{P(L)},
\]

where the sum ranges over all \( L \in \binom{\ell}{V_p} \) corresponding to some \( I \) as given by Corollary 4.3.

From Corollary 4.3 and the chosen parameters, either \(|P(L)| \leq (1 - 4\delta)\lambda N\), or \(|P(L) \setminus B| \leq \varepsilon \lambda N/2 \) for some \( B \in \mathcal{B}_n \). If \(|P(L)| \leq (1 - 4\delta)\lambda N\), due to Chernoff’s inequality (Lemma 2.8) we get

\[
\mathbb{P}(|P(L) \cap V_p| \geq (1 - 2\delta)p \lambda N) \leq \exp\{-\varepsilon^2 \lambda p N\}.
\]

Similarly, if \(|P(L) \setminus B| \leq \varepsilon \lambda N/2 \) for some \( B \in \mathcal{B}_n \), we have

\[
\mathbb{P}(|(P(L) \setminus B) \cap V_p| > \varepsilon \lambda p N) \leq \exp\{-\varepsilon^2 \lambda p N/12\}.
\]

Using that \( \delta \leq \varepsilon/4 \) we thus obtain \( q_{P(L)} \leq 2 \exp\{-\varepsilon^2 \lambda p N\} \). From 4 combined with \( \binom{N}{\ell} \leq \left( \frac{eN}{\ell} \right)^\ell \) and the choice of \( \ell \),

\[
q_T \leq \left( \frac{epN}{\ell} \right)^\ell \cdot 2 \exp\{-\varepsilon^2 \lambda p N\} \leq 2 \exp \left\{ \ell \ln \left( \frac{8eDp}{\ln(e/\lambda)} \right) - \varepsilon^2 \lambda p N \right\}.
\]
To complete the proof it is sufficient to show that
\[
\frac{\ln(e/\lambda)}{4\lambda^2 D} \leq \frac{p}{\ln \left( \frac{8e\delta pD}{\ln(e/\lambda)} \right)}.
\]

As the left hand side does not depend on \( p \), and the right hand side is monotone increasing in \( p \), it is sufficient to verify this inequality for \( p = C(\lambda D)^{-1} \ln^2(e/\lambda) \). In this case, the claim follows if we can show that
\[
\frac{1}{4\delta^3} \leq \frac{C \ln(e/\lambda)}{\ln \left( \frac{8e\delta C}{\lambda} \ln(e/\lambda) \right)}.
\]

Observe that \( 8e\delta C/\lambda > \ln(e/\lambda) \) due to our choice of \( C_2 \) and \( C \). Using this fact, it is easy to see that the required inequality holds, which completes the proof of our result. \( \square \)

Acknowledgement

The authors are grateful to Yoshiharu Kohayakawa for mentioning the problem and helpful comments. Many thanks go to Oded Regev and Ehud Friedgut for sharing a preliminary version of their paper.
