Chiral dynamics, S-wave contributions and angular analysis in $D \to \pi\pi\ell\bar{\nu}$

Yu-Ji Shi, Wei Wang * and Shuai Zhao †

INPAC, Shanghai Key Laboratory for Particle Physics and Cosmology,
Department of Physics and Astronomy, Shanghai Jiao-Tong University, Shanghai, 200240, China

We present a theoretical analysis of the $D^- \to \pi^-\pi^0\ell\bar{\nu}$ and $D^0 \to \pi^+\pi^-\ell\bar{\nu}$ decays. We construct a general angular distribution which can include arbitrary partial waves of $\pi\pi$. Retaining the S-wave and P-wave contributions we study the branching ratios, forward–backward asymmetries and a few other observables. The P-wave contribution is dominated by $\rho^0$ resonance, and the S-wave contribution is analyzed using the unitarized chiral perturbation theory. The obtained branching fraction for $D \to \rho\ell\bar{\nu}$, at the order $10^{-3}$, is consistent with the available experimental data. The S-wave contribution has a branching ratio at the order of $10^{-4}$, and this prediction can be tested by experiments like BESIII and LHCb. Future measurements can also be used to examine the $\pi\pi$ scattering phase shift.

I. INTRODUCTION

The Cabbibo–Kobayashi–Maskawa (CKM) matrix elements are key parameters in the Standard Model (SM). They are essential to understand CP violation within the SM and search for new physics (NP). Among these matrix elements, $|V_{cd}|$ can be determined from either exclusive or inclusive weak $D$ decays, which are governed by $c \to d$ transition, for example, $c \to d\ell\bar{\nu}$ transitions. However, for a general $D$ decay process it is difficult to extract CKM matrix elements, because strong and weak interactions may be entangled.

The semi-leptonic $D$ decays are ideal channels to determine $|V_{cd}|$, not only because the weak and strong dynamics can be separated in these process, but also the clean experimental signals. Moreover, one can study the dynamics in the heavy-to-light transition from semi-leptonic $D$ decays. For leptons do not participate in the strong interaction, all the strong dynamics is included in the form factors; thus it provides a good platform to measure the form factors.

The $D \to \rho$ form factors have been measured from $D^0 \to \rho^-e^+\nu_e$ and $D^+ \to \rho^0e^+\nu_e$ at the CLEO-c experiment for both charged and neutral channels [1]. Because of the large width of the $\rho$ meson, $D \to \rho\ell\bar{\nu}$ is in fact a quasi-four body process $D \to \pi\pi\ell\bar{\nu}_\ell$. The $\rho$ can be reconstructed from the P-wave $\pi\pi$ mode. However, other $\pi\pi$ resonant or non-resonant states may interfere with the P-wave $\pi\pi$ pair, and thus it is necessary to analyze the S-wave contribution to $D \to \pi\pi\ell\bar{\nu}_\ell$.

In addition, the internal structure of light mesons is an important issue in hadron physics. It is difficult to study light mesons by QCD perturbation theory due to the large strong coupling in the low energy region. On the other hand, because of the large mass scale, one can establish factorization for many heavy meson decay processes, thus heavy mesons like $B$ and $D$ can be used to probe the internal structure of light mesons [2, 3]. As mentioned above, $D \to \pi\pi\ell\bar{\nu}_\ell$ can receive contributions from various partial waves of $\pi\pi$. $\rho(770)$ dominant for $D$ to P-wave $\pi\pi$ decay, at the same time, $D$ meson can decay into S-wave $\pi\pi$ through $f_0(980)$. The structure of $f_0(980)$ is not fully understood yet. Analysis of $D \to \pi\pi\ell\bar{\nu}_\ell$ may shed more light on understanding the nature of $f_0(980)$. The BESIII collaboration has collected 2.93 fb$^{-1}$ data in $e^+e^-$ collisions at the energy around 3.773 GeV [4], which can be used to study the semi-leptonic $D$ decays. Thus it presently is mandatory to make reliable theoretical predictions. Some analyses of multi-body heavy meson decays can be found in Refs. [2, 4], where the final state interactions between the light pseudoscalar mesons are taken into account.

In this paper we present a theoretical analysis of $D^- \to \pi^+\pi^-\ell\bar{\nu}_\ell$ and $D^0 \to \pi^+\pi^-\ell\bar{\nu}_\ell$ decays. In Sec. II, we will present the results of $D \to f_0(980)$ and $D \to \rho$ form factors. We also calculate $D$ to S-wave $\pi\pi$ pair form factors in...
FIG. 1: Feynman diagram for the $D \to \pi\pi\ell^{-}\bar{\nu}_\ell$ decays. The lepton could be an electron or a muon, $\ell = e, \mu$. Depending on the $D$ meson, the spectator could be a $u$ or a $d$ quark, corresponding to $D^0 \to \pi^+\pi^0\ell^{-}\bar{\nu}_\ell$ and $D^- \to \pi^+\pi^-\ell^{-}\bar{\nu}_\ell$.
TABLE I: $D \to \rho$ form factors derived by LFQM (left) $^{23,24}$ and LCSR (right) $^{25}$, respectively.

| LFQM     | $F(0)$       | $a$    | $b$    | $F(0)$       | $a$    | $b$    |
|----------|--------------|--------|--------|--------------|--------|--------|
| $V_{D\to\rho}$ | $0.88 \pm 0.03$ | $1.23 \pm 0.01$ | $0.40 \pm 0.04$ | $V_{D\to\rho}$ | $0.801 \pm 0.044$ | $0.78 \pm 0.24$ | $2.61 \pm 0.29$ |

TABLE II: Fitted parameters of the $D \to f_0$ form factors derived by LCSR, which are fitted using Eq. (3).

| $D \to f_0$ | $F(0)$       | $a$    | $b$    |
|-------------|--------------|--------|--------|
| $F_1$       | $0.321 \pm 0.010$ | $0.990 \pm 0.032$ | $0.543 \pm 0.023$ |
| $F_0$       | $0.321 \pm 0.010$ | $0.344 \pm 0.019$ | $-0.735 \pm 0.001$ |

distribution in the full kinematics region, the following parametrization has been used:

$$F_i(q^2) = \frac{F_i(0)}{1 - a_i \frac{q^2}{m_{D}^2} + b_i \left( \frac{q^2}{m_{D}^2} \right)^2}.$$  \hfill (3)

Their results are collected in Tab. II. We note that a different parametrization is adopted in Ref. 25, where $A_3$ appears instead of $A_0$. The relation between $A_0$ and $A_3$ is given by

$$A_0(q^2) = \frac{1}{2m_{\rho}(m_{D} + m_{\rho})} \left[ A_1(q^2)(m_{D} + m_{\rho})^2 + A_2(q^2)(m_{\rho}^2 - m_{D}^2) - A_3(q^2)q^2 \right]. \hfill (4)$$

B. Scalar $\pi\pi$ form factor and $D$ to S-wave $\pi\pi$

We first give the $D \to f_0(980)$ form factor parametrized as

$$\langle f_0(p_2)|\bar{d}\gamma_{\mu}\gamma_5c|D^-(p_D)\rangle = -i \left\{ F^{D\to f_0}_{+}(q^2) \left[ P_{\mu} - \frac{m_{D}^2 - m_{f_0}^2}{q^2} q_\mu \right] + F^{D\to f_0}_{0}(q^2) \frac{m_{D}^2 - m_{f_0}^2}{q^2} q_\mu \right\}, \hfill (5)$$

where $F^{D\to f_0}_{+}$ and $F^{D\to f_0}_{0}$ are $D \to f_0$ form factors. We will use LCSR to compute the $D \to f_0(980)$ transition form factors with some inputs, and we refer the reader to Ref. 26 for a detailed derivation in LCSR. The meson masses are fixed to the PDG values $m_{D} = 1.870$ GeV and $m_{f_0} = 0.99$ GeV 27. For quark masses we use $m_c = 1.27$ GeV 27 and $m_d = 5$ MeV. As for decay constants, we use $f_D = 0.21$ GeV 27 and $f_{f_0} = 0.18$ GeV 28. The threshold $s_0$ is fixed at $s_0 = 4.1$ GeV$^2$, which should correspond to the squared mass of the first radial excitation of $D$. The parameters $F_i(0)$, $a_i$ and $b_i$ are fitted in the region $-0.5$ GeV$^2 < q^2 < 0.5$ GeV$^2$, and the Borel parameter $M^2$ is taken to be $(6 \pm 1)$ GeV$^{-2}$. With these parametrizations, we give the numerical results in Tab. II.

In the region where the two pseudo-scalar mesons strongly interacts, the resonance approximation fails and thus has to be abandoned. One of the such examples is the S-wave partial wave under 1 GeV, for which we can use the form factors as defined in Ref. 24:

$$\langle (\pi\pi)_S(p_{\pi\pi})|\bar{u}\gamma_{\mu}\gamma_5c|D(p_D)\rangle = -i \left\{ \frac{1}{m_{\pi\pi}} \left[ P_{\mu} - \frac{m_{D}^2 - m_{\pi\pi}^2}{q^2} q_\mu \right] F^{D\to\pi\pi}_{+}(m_{\pi\pi}^2, q^2) + \frac{m_{D}^2 - m_{\pi\pi}^2}{q^2} q_\mu F^{D\to\pi\pi}_{0}(m_{\pi\pi}^2, q^2) \right\}. \hfill (6)$$
The Watson theorem implies that phases measured in $\pi\pi$ elastic scattering and in a decay channel in which the $\pi\pi$ system has no strong interaction with other hadrons are equal modulo $\pi$ radians. In the process we consider here, the lepton pair $\ell\bar{\nu}$ indeed decouples from the $\pi\pi$ final state, and thus the phases of $D$ to scalar $\pi\pi$ decay amplitudes are equal to $\pi\pi$ scattering with the same isospin. It is plausible that

$$\langle (\pi\pi)_S | \bar{d}\Gamma | D \rangle \propto F_{\pi\pi}(m_{\pi\pi}^2),$$

(7)

where the scalar form factor is defined as

$$\langle 0 | \bar{d}d | \pi^+\pi^- \rangle = B_0 F_{\pi\pi}(m_{\pi\pi}^2),$$

(8)

where $B_0 = (1.7 \pm 0.2)$ GeV \[^{10}\] is the QCD condensate parameter.

An explicit calculation of these quantities requires knowledge of generalized light-cone distribution amplitudes (LCDAs) \[^{30}\]. The twist-3 one has the same asymptotic form with the LCDAs for a scalar resonance \[^{31}\]. Inspired by this similarity, we may plausibly introduce an intuitive matching between the $D \rightarrow f_0$ and $D \rightarrow (\pi\pi)_S$ form factors \[^{7}\]:

$$F_i^{D \rightarrow \pi\pi}(m_{\pi\pi}^2, q^2) \approx B_0 \frac{1}{f_{f_0}} F_{\pi\pi}(m_{\pi\pi}^2) F_i^{D \rightarrow f_0}(q^2).$$

(9)

It is necessary to stress at this stage that the Watson theorem does not strictly guarantee that one may use Eq. (9). Instead it indicates that, below the opening of inelastic channels the strong phases in the $D \rightarrow \pi\pi$ form factor and $\pi\pi$ scattering are the same. First above the $4\pi$ or $KK$ threshold, additional inelastic channels will also contribute. The $KK$ contribution can be incorporated in a coupled-channel analysis. As a process-dependent study, it has been demonstrated that states with two additional pions may not give sizable contributions to the physical observables \[^{32}\].

Secondly, some polynomials with nontrivial dependence on $m_{\pi\pi}$ have been neglected in Eq. (9). In principle, once the generalized LCDAs for the $(\pi\pi)_S$ system are known, the $D \rightarrow \pi\pi$ form factor can be straightforwardly calculated in LCSR and thus this approximation in the matching equation can be avoided. On the one side, the space-like generalized parton distributions for the pion have been calculated at one-loop level in the chiral perturbation theory (\(\chi PT\)) \[^{33}\]. The analysis of time-like generalized LCDAs in \(\chi PT\) and the unitarized framework is in progress. On the other side, the $\gamma\gamma^* \rightarrow \pi^+\pi^-$ reaction is helpful to extract the generalized LCDAs for the $(\pi\pi)_S$ system \[^{34, 35}\]. The experimental prospects at BEPC-II and BELLE-II in the near future are very promising.

In the kinematic region where the $\pi$ is soft, the crossed channel from $D + \pi \rightarrow \pi$ will contribute as well and this crossed channel would modify Eq. (9) by an inhomogeneous part. For the analogous decay of $K$ or $B$ mesons, it has been taken into account either dynamically in terms of phase shifts (in the case of the kaon decay) \[^{36}\] or approximately in terms of a pole contribution (in the case of the $B$ meson decay) \[^{12}\]. However, if both pions move fast, the $D - \pi$ invariant mass is far from the $D^*$ pole and this contribution is negligible. In this case, the transition amplitude for the $D$ to 2-pion form factor can be calculated in light-cone sum rules \[^{4}\]. This will lead to the conjectured formula in Eq. (9).

The scalar $\pi\pi$ form factor can be handled using the unitarized chiral perturbation theory. In the following, we will give a brief description of this approach. In terms of the isoscalar $S$-wave states

$$|\pi\pi\rangle_{I=0} = \frac{1}{\sqrt{3}} |\pi^+\pi^-\rangle + \frac{1}{\sqrt{6}} |\pi^0\pi^0\rangle,$$

(10)

$$|K\bar{K}\rangle_{I=0} = \frac{1}{\sqrt{2}} |K^+K^-\rangle + \frac{1}{\sqrt{2}} |K^0\bar{K}^0\rangle,$$

(11)

the scalar form factors for the $\pi$ and $K$ mesons are defined as

$$\sqrt{2}B_0 F_1^{n/s}(s) = \langle 0 | \bar{n}n/\bar{s}s|\pi\pi\rangle_{I=0},$$

$$\sqrt{2}B_0 F_2^{n/s}(s) = \langle 0 | \bar{n}n/\bar{s}s|K\bar{K}\rangle_{I=0},$$

(12)
where \( s = m^2_{\pi\pi} \). The \( i\eta = (\bar{u}u + \bar{d}d) / \sqrt{2} \) denotes the non-strange scalar current, and the notation \((\pi = 1, K = 2)\) has been introduced for simplicity. With the above notation, we have

\[
F_{\pi\pi}(m^2_{\pi\pi}) = \sqrt{3} F_1'(m^2_{\pi\pi}).
\]

(13)

Expressions have already been derived in \( \chi \)PT up to next-to-leading order \[37, 40\]:

\[
F_1'(s) = \sqrt{3} \frac{2}{2} \left[ 1 + \mu_i - \frac{\mu_i}{3} + \frac{16m^2_{\pi} + 8(2L_6' - L_4)}{f^2} \left( 2L_6' - L_4 \right) + 8 \left( 2L_6' - L_4 \right) \frac{2m^2_K + 3m^2_{\pi} + 8s}{f^2} + \frac{4s}{f^2} \right]
\]

(14)

\[
F_2'(s) = \frac{1}{\sqrt{2}} \left[ 1 + \frac{8L_6'}{f^2} \left( 2s - m^2_{\pi} - 6m^2_K \right) + \frac{4L_6'}{f^2} \left( s - 4m^2_K \right) + \frac{16L_6'}{f^2} \left( 6m^2_K + m^2_{\pi} \right) + \frac{32L_6'}{f^2} \right]
\]

(15)

\[
F_2'(s) = \frac{1}{\sqrt{2}} \left[ 1 + \frac{8L_6'}{f^2} \left( s - m^2_{\pi} - 4m^2_K \right) + \frac{4L_6'}{f^2} \left( s - 4m^2_K \right) + \frac{16L_6'}{f^2} \left( 4m^2_K + m^2_{\pi} \right) + \frac{32L_6'}{f^2} \right]
\]

(16)

\[
J_{\pi\pi}(s) = \frac{1}{16\pi^2} \left[ 1 - \log \left( \frac{m^2_{\pi}}{\mu^2} \right) \right] - \sigma_i(s) \log \left( \frac{\sigma_i(s) + 1}{\sigma_i(s) - 1} \right)
\]

(19)

Here the \( L_6' \) are the renormalized low-energy constants, and \( f \) is the pion decay constant at tree level. The \( \mu_i \) and \( J_{i\pi} \) are defined as follows:

\[
\mu_i = \frac{m_i}{32\pi^2 f^2} \ln \frac{m_i}{\mu^2},
\]

(18)

\[
J_{i\pi}(s) = \frac{1}{16\pi^2} \left[ 1 - \log \left( \frac{m^2_{\pi}}{\mu^2} \right) - \sigma_i(s) \log \left( \frac{\sigma_i(s) + 1}{\sigma_i(s) - 1} \right) \right],
\]

(19)

with \( \sigma_i(s) = \sqrt{1 - 4m^2_i/s} \). It is interesting to note that the next-to-next-to-leading order results can also be found in Refs. \[41, 42\]. Imposing the unitarity constraints, the scalar form factor can be expressed in terms of the algebraic coupled-channel equation

\[
F(s) = [I + K(s) g(s)]^{-1} R(s)
\]

(20)

where \( R(s) \) has no right-hand cut and in the second line, the equation has been expanded up to NLO in the chiral expansion. \( K(s) \) is the S-wave projected kernel of meson-meson scattering amplitudes that can be derived from the leading-order chiral Lagrangian:

\[
K_{11} = \frac{2s - m^2_{\pi}}{2f^2}, \quad K_{12} = K_{21} = \frac{\sqrt{3} s}{4f^2}, \quad K_{22} = \frac{3s}{4f^2}.
\]

The loop integral can be calculated either in the cutoff-regularization scheme with \( q_{\text{max}} \sim 1 \) GeV being the cutoff (cf. Erratum of Ref. \[43\] for an explicit expression) or in dimensional regularization with the \( \overline{\text{MS}} \) subtraction scheme. In the latter scheme, the meson loop function \( g_i(s) \) is given by

\[
J_{i\pi}(s) \equiv \frac{1}{16\pi^2} \left[ 1 - \log \left( \frac{m^2_{\pi}}{\mu^2} \right) - \sigma_i(s) \log \left( \frac{\sigma_i(s) + 1}{\sigma_i(s) - 1} \right) \right]
\]

(21)
FIG. 2: The non-strange $\pi\pi$ scalar form factor obtained in the unitarized chiral perturbation theory. The modulus, real part and imaginary part are shown in solid, dashed and dotted curves.

The expressions for the $R_i$ are obtained by matching the unitarization and chiral perturbation theory \[44, 45\]:

\begin{align*}
R_1^n(s) & = \frac{\sqrt{3}}{2} \left\{1 + \mu_\pi - \frac{\mu_\eta}{3} + \frac{16m_\pi^2}{f^2} (2L_6^5 - L_5^5) + 8 (2L_6^5 - L_4^5) \frac{2m_\pi^2 + 3m_\pi^2}{f^2} + \frac{8s}{f^2} L_4^5 + \frac{4s}{f^2} L_5^5 \right. \\
& \left. - \frac{m_\pi^2}{288\pi^2 f^2} \left[1 + \log \left( \frac{m_\eta^2}{\mu^2} \right) \right] \right\}, \\
R_2^n(s) & = \frac{\sqrt{3}}{2} \left\{16m_\pi^2 f^2 (2L_6^5 - L_4^5) + \frac{8s}{f^2} L_4^5 - \frac{m_\pi^2}{72\pi^2 f^2} \left[1 + \log \left( \frac{m_\eta^2}{\mu^2} \right) \right] \right\}, \\
R_1^s(s) & = \frac{1}{\sqrt{2}} \left\{1 + 8L_4^5 \frac{f^2}{(s - 6m_K^2 - m_\pi^2)} + \frac{4L_5^5}{f^2} (s - 4m_K^2) + \frac{16L_6^5}{f^2} (6m_K^2 + m_\pi^2) + \frac{32L_5^5}{f^2} m_K^2 + \frac{2}{3} \mu_\eta \right. \\
& \left. + \frac{m_\pi^2}{72\pi^2 f^2} \left[1 + \log \left( \frac{m_\eta^2}{\mu^2} \right) \right] \right\}, \\
R_2^s(s) & = \frac{1}{\sqrt{2}} \left\{1 + \frac{8L_4^5}{f^2} (s - 4m_K^2 - m_\pi^2) + \frac{4L_5^5}{f^2} (s - 4m_K^2) + \frac{16L_6^5}{f^2} (4m_K^2 + m_\pi^2) + \frac{32L_5^5}{f^2} m_K^2 + \frac{2}{3} \mu_\eta \right. \\
& \left. + \frac{m_\pi^2}{36\pi^2 f^2} \left[1 + \log \left( \frac{m_\eta^2}{\mu^2} \right) \right] \right\}. 
\end{align*}

With the above formulas and the fitted results for the low-energy constants $L_i^r$ in Ref. \[45\] (evolved from $M_\rho$ to the scale $\mu = 2q_{\text{max}}/\sqrt{e}$), we show the non-strange $\pi\pi$ form factor in Fig. 2. The modulus, real part and imaginary part are shown as solid, dashed and dotted curves. As the figure shows, the chiral unitary ansatz predicts a form factor $F_1^n$ with a zero close to the $\bar{K}K$ threshold. This feature has been extensively discussed in Ref. \[46\].

### III. FULL ANGULAR DISTRIBUTION OF $D \to \pi\pi\ell\bar{\nu}$

In this section, we will derive a full angular distribution of $D \to \pi\pi\ell\bar{\nu}$. For the literature, one may consult Refs. \[47, 48\]. We set up the kinematics for the $D^- \to \pi^+\pi^-\ell\bar{\nu}$ as shown in Fig. 3 which can also be used for $D^0 \to \pi^+\pi^0\ell\bar{\nu}$. The $\pi\pi$ moves along the $z$ axis in the $D^-$ rest frame. $\theta_{\pi^+}(\theta_\ell)$ is defined in the $\pi\pi$ (lepton pair) rest
frame as the angle between z-axis and the flight direction of $\pi^+$ ($\ell^-$), respectively. The azimuth angle $\phi$ is the angle between the $\pi\pi$ decay and lepton pair planes.

Decay amplitudes for $D \to \pi\pi\ell\bar{\nu}_\ell$ can be divided into several individual pieces and each of them can be expressed in terms of the Lorentz invariant helicity amplitudes. The amplitude for the hadronic part can be obtained by the evaluation of the matrix element:

$$A_\lambda = \sqrt{N_{f_0/\rho}} \frac{iG_F}{\sqrt{2}} V_{cd}^* \epsilon_\mu^\nu(h) \langle \pi\pi|\bar{c}\gamma^\mu (1 - \gamma_5) d|D\rangle,$$  \hspace{1cm} (26)

where $\epsilon_\mu(h)$ is an auxiliary polarization vector for the lepton pair system and $h = 0, \pm t$, $N_{f_0/\rho} = \sqrt{\lambda_q^2 \beta_t/(96\pi^3 m_D^3)}$, $\beta_t = 1 - \hat{m}_t^2$ and $\hat{m}_t = m_t/\sqrt{\lambda_q^2}$. $|V_{cd}|$ is taken to be 0.22 [27]. The functions $A_i$ can be decomposed into different partial waves,

$$A_{0/1}(q^2, m_{\pi\pi}^2, \theta_{\pi+}) = \sum_{J=0,1,2...} A_{0/1}^J(q^2, m_{\pi\pi}^2) Y_J^0(\theta_{\pi+}, 0),$$

$$A_{||/\perp}(q^2, m_{\pi\pi}^2, \theta_{\pi+}) = \sum_{J=0,1,2...} A_{||/\perp}^J(q^2, m_{\pi\pi}^2) Y_J^1(\theta_{\pi+}, 0),$$

$$A_{0/1}^J(q^2, m_{\pi\pi}^2) = \sqrt{N_{f_0/\rho}} M_D(f_0/\rho, 0/t)(q^2) L_{f_0/\rho}(m_{\pi\pi}^2) \equiv |A_{0/1}^J| e^{i\delta_{0/1}^J},$$

$$A_{||/\perp}^J(q^2, m_{\pi\pi}^2) = \sqrt{N_{f_0/\rho}} M_D(f_0/\rho, ||/\perp)(q^2) L_{f_0/\rho}(m_{\pi\pi}^2) \equiv |A_{||/\perp}^J| e^{i\delta_{||/\perp}^J}. \hspace{1cm} (27)$$

Here $J$ denotes the partial wave of the $\pi\pi$ system and the script $t$ denotes the time-like component of a virtual vector/axial-vector meson decays into a lepton pair. The $L_{f_0/\rho}(m_{\pi\pi}^2)$ is the lineshape and for the P-wave $\rho$ we use the Breit–Wigner distribution:

$$L_{\rho}(m_{\pi\pi}^2) = \sqrt{\frac{m_\rho \Gamma_{\rho \to \pi\pi}}{\pi}} \frac{1}{m_{\pi\pi}^2 - m_\rho^2 + im_\rho \Gamma_\rho}. \hspace{1cm} (28)$$

Considering the momentum dependence of the $\rho$ decay, we have the running width as

$$\Gamma_\rho(m_{\pi\pi}^2) = \Gamma_\rho^0 \left( \frac{|\vec{q}|}{|\vec{q}_0|} \right)^3 \frac{m_\rho}{m_{\pi\pi}} \frac{1 + (R|\vec{q}_0|)^2}{1 + (R|\vec{q}|)^2}, \hspace{1cm} (29)$$

and the Blatt–Weisskopf parameter $R = (2.1 \pm 0.5 \pm 0.5) \text{ GeV}^{-1}$ [49].
The spin-0 final state has only one polarization state and the amplitudes are

\[ iM_D(f_0, 0) = N_1 i \frac{\sqrt{\lambda}}{\sqrt{q^2}} F_1(q^2), \quad iM_D(f_0, t) = N_1 i \frac{m_D^2 - m_\pi^2}{\sqrt{q^2}} F_0(q^2), \]  

(30)

with \( N_1 = i G_F V_{ud}^* / \sqrt{2} \). For mesons with spin \( J \geq 1 \), the \( \pi^+ \pi^- \) system can be either longitudinally or transversely polarized and thus we have the following form:

\[ iM_D(\rho, 0) = -\frac{\alpha_L^I N_1 i}{2m_\rho \sqrt{q^2}} \left[ (m_D^2 - m_\rho^2 - q^2)(m_D + m_\rho)A_1 - \frac{\lambda}{m_D + m_\rho} A_2 \right], \]

\[ iM_D(\rho, \pm) = -\beta_T^I N_1 i \left[ (m_D + m_\rho)A_1 \pm \frac{\sqrt{\lambda}}{m_D + m_\rho} V \right], \]

(31)

\[ iM_D(\rho, t) = -\alpha_L^I N_1 \frac{\sqrt{\lambda}}{\sqrt{q^2}} A_0. \]

(32)

The \( \alpha_L^I \) and \( \beta_T^I \) are products of the Clebsch–Gordan coefficients

\[ \alpha_L^I = C^I_{1,0,J-1,0}C^I_{0,1,0,J-2,0} \cdots C^I_{1,0,1,0}, \quad \beta_T^I = C^{1,1}_{1,1,J-1,0}C^{I-1,0}_{1,1,J-2,0} \cdots C^0_{1,0,1,0}. \]

(33)

For the sake of convenience, we define

\[ iM_D(\rho, \perp / ||) = \frac{1}{\sqrt{2}}[iM_D(\rho, +) \mp iM_D(\rho, -)], \]

\[ iM_D(\rho, \perp) = -i\beta_T^I \sqrt{2} N_1 \left[ \frac{\sqrt{\lambda}}{m_D + m_\rho} \right], \quad iM_D(\rho, ||) = -i\beta_T^I \sqrt{2} N_1 [(m_D + m_\rho)A_1]. \]

(34)

Using the generalized form factor, the matrix elements for \( D \) decays into the spin-0 non-resonating \( \pi \pi \) final state are given as

\[ A_0^{\pi \pi} = \sqrt{N_2} \frac{1}{m_{\pi\pi}} \left[ \frac{\sqrt{\lambda}}{\sqrt{q^2}} F_1(m_{\pi\pi}, q^2) \right], \quad A_t^{\pi \pi} = \sqrt{N_2} \frac{1}{m_{\pi\pi}} \left[ \frac{m_D^2 - m_{\pi\pi}^2}{\sqrt{q^2}} F_0(m_{\pi\pi}, q^2) \right], \]

(35)

\[ N_2 = N_1 \rho_{\pi\pi} / (16\pi^2), \text{ with } \rho_{\pi\pi} = \sqrt{1 - 4m_{\pi\pi}^2/m_{\pi\pi}^2}. \]

The above quantities can lead to the full angular distributions

\[
\frac{d^3 \Gamma}{dm_{\pi\pi}^2 dq^2 d \cos \theta_\pi d \cos \theta_\ell d \phi} = 3 \left[ I_1(q^2, m_{\pi\pi}^2, \theta_\pi^+) + I_2(q^2, m_{\pi\pi}^2, \theta_\pi^+) \cos(2\ell t) + I_3(q^2, m_{\pi\pi}^2, \theta_\pi^+) \sin^2 \theta_\ell \cos \phi \right]
\]

\[
+ \left[ I_4(q^2, m_{\pi\pi}^2, \theta_\pi^+) \cos(2\ell t) \sin \phi + I_5(q^2, m_{\pi\pi}^2, \theta_\pi^+) \sin \phi \cos \phi \right]
\]

\[
+ \left[ I_6(q^2, m_{\pi\pi}^2, \theta_\pi^+) \sin \theta_\ell \cos \phi \right] + \left[ I_7(q^2, m_{\pi\pi}^2, \theta_\pi^+) \sin \phi \right] + \left[ I_8(q^2, m_{\pi\pi}^2, \theta_\pi^+) \sin(2t \ell) \sin \phi \right] + \left[ I_9(q^2, m_{\pi\pi}^2, \theta_\pi^+) \sin^2 \theta_\ell \sin(2\phi) \right].
\]

(36)

For the general expressions of \( I_i \), we refer the reader to the appendix and to Refs. [48, 50] for the formulas with the S-, P- and D-waves. In the following, we shall only consider the S-wave and P-wave contributions and thus the above
general expressions are reduced to:

\[
I_1 = \frac{1}{4\pi} \left[ (1 + \hat{m}_t^2) |A_0^0|^2 + 2\hat{m}_t^2 |A_0^1|^2 \right] + \frac{3}{4\pi} \cos^2 \theta_{\pi^+} \left[ (1 + \hat{m}_t^2) |A_0^0|^2 + 2\hat{m}_t^2 |A_0^1|^2 \right] + \frac{2\sqrt{3} \cos \theta_{\pi^+}}{4\pi} \left[ (1 + \hat{m}_t^2) \text{Re}[A_0^0 A_0^{*1}] + 2\hat{m}_t^2 \text{Re}[A_0^1 A_1^{*1}] \right] + \frac{3 + \hat{m}_t^2}{2} \frac{3}{8\pi} \sin^2 \theta_{\pi^+} (|A_1^1|^2 + |A_1^1|^2),
\]

\[
I_2 = -\beta \left\{ \frac{1}{4\pi} |A_0^0|^2 + \frac{3}{4\pi} \cos^2 \theta_{\pi^+} |A_0^1|^2 + \frac{2\sqrt{3} \cos \theta_{\pi^+}}{4\pi} \text{Re}[A_0^0 A_0^{*1}] \right\} + \frac{1}{2} \beta \frac{3}{8\pi} \sin^2 \theta_{\pi^+} (|A_1^1|^2 + |A_1^1|^2),
\]

\[
I_3 = \beta \frac{3}{8\pi} \sin^2 \theta_{\pi^+} (|A_1^1|^2 - |A_1^1|^2),
\]

\[
I_4 = 2\beta \left[ \frac{\sqrt{3} \sin \theta_{\pi^+} \text{Re}[A_0^0 A_0^{*1}]}{\sqrt{2\pi}} + \frac{3 \sin \theta_{\pi^+} \cos \theta_{\pi^+} \text{Re}[A_0^1 A_1^{*1}]}{4\sqrt{2\pi}} \right],
\]

\[
I_5 = 4 \left\{ \frac{\sqrt{3} \sin \theta_{\pi^+} (\text{Re}[A_0^0 A_1^{*1}] - \hat{m}_t^2 \text{Re}[A_0^1 A_1^{*1}])}{4\sqrt{2\pi}} + \frac{3 \sin \theta_{\pi^+} \cos \theta_{\pi^+} (\text{Re}[A_0^1 A_1^{*1}] - \hat{m}_t^2 \text{Re}[A_0^0 A_1^{*1}])}{4\sqrt{2\pi}} \right\},
\]

\[
I_6 = 4 \left\{ \frac{3}{8\pi} \sin^2 \theta_{\pi^+} \text{Re}[A_1^1 A_1^{*1}] + \hat{m}_t^2 \frac{1}{4\pi} \text{Re}[A_1^0 A_0^1] + \hat{m}_t^2 \frac{3}{4\pi} \cos^2 \theta_{\pi^+} \text{Re}[A_1^1 A_0^1] \right\},
\]

\[
I_7 = 4 \left\{ \frac{\sqrt{3}}{4\sqrt{2\pi}} \sin \theta_{\pi^+} \text{Im}[A_0^0 A_1^{*1}] - \hat{m}_t^2 \text{Im}[A_0^1 A_1^{*1}] \right\} + \frac{3}{4\sqrt{2\pi}} \sin \theta_{\pi^+} \cos \theta_{\pi^+} \text{Im}[A_1^0 A_1^{*1}] \right\},
\]

\[
I_8 = 2\beta \left\{ \frac{\sqrt{3}}{4\sqrt{2\pi}} \sin \theta_{\pi^+} \text{Im}[A_0^0 A_1^{*1}] + \frac{3}{4\sqrt{2\pi}} \sin \theta_{\pi^+} \cos \theta_{\pi^+} \text{Im}[A_0^0 A_1^{*1}] \right\},
\]

\[
I_9 = 2\beta \frac{3}{8\pi} \sin^2 \theta_{\pi^+} \text{Im}[A_1^1 A_1^{*1}].
\]

Since the phase in P-wave contributions arise from the lineshape which is the same for different polarizations, the $I_9$ term and the second line in the $I_7$ are zero.

### A. Differential and integrated decay widths

Using the narrow width approximation, we obtain the integrated branching fraction:

\[
B(D^- \to \rho^0 e^- \bar{\nu}) = (2.24 \pm 0.09) \times 10^{-3} / (2.16 \pm 0.36) \times 10^{-3} \text{(LFQM/LCSR)},
\]

\[
B(D^- \to \rho^0 \mu^- \bar{\nu}) = (2.15 \pm 0.08) \times 10^{-3} / (2.06 \pm 0.35) \times 10^{-3} \text{(LFQM/LCSR)},
\]

\[
B(D^0 \to \rho^+ e^- \bar{\nu}) = (1.73 \pm 0.07) \times 10^{-3} / (1.67 \pm 0.27) \times 10^{-3} \text{(LFQM/LCSR)},
\]

where theoretical errors are from the heavy-to-light transition form factors. These theoretical results are in good agreement with the data:

\[
B(D^- \to \rho^0 e^- \bar{\nu}) = (2.18^{+0.17}_{-0.25}) \times 10^{-3},
\]

\[
B(D^- \to \rho^0 \mu^- \bar{\nu}) = (2.4 \pm 0.4) \times 10^{-3},
\]

\[
B(D^0 \to \rho^+ e^- \bar{\nu}) = (1.77 \pm 0.16) \times 10^{-3}.
\]

The starting point for detailed analysis of $D \to \pi \pi \ell \bar{\nu}$ is to obtain the double-differential distribution $d^2\Gamma / dq^2 dm_{\pi \pi}^2$ after performing integration over all the angles

\[
\frac{d^2\Gamma}{dq^2 dm_{\pi \pi}^2} = \left( 1 + \frac{\hat{m}_t^2}{2} \right) (|A_0^0|^2 + |A_0^1|^2 + |A_1|^2 + |A_1^1|^2) + \frac{3}{2} \hat{m}_t^2 (|A_1^1|^2 + |A_0^1|^2),
\]

where apparently in the massless limit for the involved lepton, the total normalization for angular distributions changes to the sum of the S-wave and P-wave amplitudes

\[
\frac{d^2\Gamma}{dq^2 dm_{\pi \pi}^2} = |A_0^0|^2 + |A_0^1|^2 + |A_1|^2 + |A_1^1|^2.
\]
In Fig. 4, we give the dependence of branching fraction on $m_{\pi\pi}$ in the $D^- \rightarrow \pi^+\pi^- e^-\bar{\nu}_e$ process. The solid, dashed, and dotted curves correspond to the total, S-wave and P-wave contributions. For the S-wave contribution, there is no resonance around 0.98 GeV, and theoretically, this should be a dip.

Due to the quantum number constraint, the process $\bar{D}_0 \rightarrow \pi^+\pi^0\ell\bar{\nu}$ receives only a P-wave contribution and $D^- \rightarrow \pi^0\pi^0\ell\bar{\nu}$ is generated by the S-wave term.

![Figure 4](image_url)  
**FIG. 4:** The dependence of branching fraction on $m_{\pi\pi}$ in the $D^- \rightarrow \pi^+\pi^- e^-\bar{\nu}_e$ process. The heavy-to-light form factors are evaluated by using LCSR.

![Figure 5](image_url)  
**FIG. 5:** Differential decay widths for the $D^- \rightarrow \pi^+\pi^- \ell\bar{\nu}_\ell$ with $\ell = e$ in panel (a) and $\ell = \mu$ in panel (b). The $q^2$-dependent ratio $R_{\mu/e}^{\pi\pi}$ as defined in Eq. (55) is given in panel (c). The dashed and dotted curves are produced using the LFQM and LCSR results for $D \rightarrow \rho$ form factors. Errors from the form factors are shown as shadowed bands, and most errors cancel in the ratio $R_{\mu/e}^{\pi\pi}$ given in panel (c).

To match the kinematics constraints implemented in experimental measurements, one may explore the generic observable with $m_{\pi\pi}^2$ integrated out:

$$\langle O \rangle = \int_{(m_\rho - \delta_m)^2}^{(m_\rho + \delta_m)^2} \frac{dO}{dm_{\pi\pi}^2} \frac{dm_{\pi\pi}^2}{dm_{\pi\pi}^2}$$  \hspace{1cm} (46)
We use the following choice in our study of $D \to \pi\pi\ell\nu$:

$$\delta_m = \Gamma_\rho.$$  \hspace{1cm}  (47)

In the narrow width-limit, the integration of the lineshape is conducted as

$$\int dm_{\pi\pi}^2 |L_\rho(m_{\pi\pi}^2)|^2 = B(\rho^0 \to \pi^- \pi^+) = 1.$$  \hspace{1cm}  (48)

However, with the explicit form given in Eq. (29), we find that the integration

$$\int_{(m_\rho - \delta_m)^2}^{(m_\rho + \delta_m)^2} dm_{\pi\pi}^2 |L_\rho(m_{\pi\pi}^2)|^2 = 0.70$$  \hspace{1cm}  (49)

is below the expected value. On the other hand, the integrated S-wave lineshape in this region is

$$\int_{(m_\rho - \delta_m)^2}^{(m_\rho + \delta_m)^2} dm_{\pi\pi}^2 |L_S(m_{\pi\pi}^2)|^2 = 0.37,$$  \hspace{1cm}  (50)

which is smaller but at the same order. Integrated from $m_\rho - \Gamma_\rho$ to $m_\rho + \Gamma_\rho$, we have

$$B(D^- \to \rho^0 (\to \pi^+ \pi^-) e^- \bar{\nu}) = (1.57 \pm 0.07) \times 10^{-3}/(1.51 \pm 0.26) \times 10^{-3} \text{ (LFQM/LCSR)},$$

$$B(D^- \to \rho^0 (\to \pi^+ \pi^-) \mu^- \bar{\nu}) = (1.57 \pm 0.07) \times 10^{-3}/(1.51 \pm 0.26) \times 10^{-3} \text{ (LFQM/LCSR)}.$$  \hspace{1cm}  (51) \hspace{1cm} (52)

The S-wave branching fractions for $2m_\pi < m_{\pi\pi} < 1.0 \text{ GeV}$ are given as

$$B(D^- \to (\pi^+ \pi^-)_{S} e^- \bar{\nu}) = (6.99 \pm 2.46) \times 10^{-4},$$

$$B(D^- \to (\pi^+ \pi^-)_{S} \mu^- \bar{\nu}) = (7.20 \pm 2.52) \times 10^{-4}.$$  \hspace{1cm}  (53) \hspace{1cm} (54)

Above $1 \text{ GeV}$, the unitarized $\chi$PT will fail and thus we lack any reliable prediction.

Furthermore, one may explore the $q^2$-dependent ratio

$$R_{\pi\pi}^{\ell/e}(q^2) = \frac{(d\Gamma(D \to \pi\pi\ell\nu)/dq^2)}{(d\Gamma(D \to \pi\pi\ell\nu)/dq^2)}.$$  \hspace{1cm}  (55)

Differential decay widths for $D \to \pi\pi\ell\nu$ are given in Fig. [5] with $\ell = e$ in panel (a) and $\ell = \mu$ in panel (b). The $q^2$-dependent ratio $R_{\pi\pi}^{\ell/e}$ is given in panel (c). Errors from the form factors and QCD condensate parameter $B_0$ are shown as shadowed bands, and most errors cancel in the ratio $R_{\pi\pi}^{\ell/e}$ given in panel (c).

### B. Distribution in $\theta_{\pi^+}$

We explore the distribution in $\theta_{\pi^+}$:

$$\frac{d^3\Gamma}{dq^2dm_{\pi\pi}^2d\cos\theta_{\pi^+}} = \frac{\pi}{2} (3I_1 - I_2)$$

$$= \frac{1}{8} \left\{ (4 + 2\hat{m}_7^2)|A_0^0|^2 + 6\hat{m}_7^2|A_1^0|^2 
+ \sqrt{3}(8 + 4\hat{m}_7^2)\cos\theta_{\pi^+} \text{ Re}[A_0^0 A_1^{*0}] + 12\sqrt{3}\hat{m}_7^2 \cos\theta_{\pi^+} \text{ Re}[A_0^0 A_1^{*1}] 
+ (12 + 6\hat{m}_7^2)|A_0^0|^2 \cos^2\theta_{\pi^+} + 18\hat{m}_7^2 \cos^2\theta_{\pi^+} |A_1^0|^2 
+ (6 + 3\hat{m}_7^2)\sin^2\theta_{\pi^+} (|A_1^0|^2 + |A_1^1|^2) \right\}. $$  \hspace{1cm}  (56)

Compared to the distribution with only P-wave contribution, namely $D \to \rho(\to \pi\pi)\ell\nu$, the first two lines of Eq. (56) are new: the first one is the S-wave $\pi\pi$ contribution, while the second line arises from the interference of S-wave and
P-wave. Based on this interference, one can define a forward–backward asymmetry for the involved pion,

\[ A_{FB}^\pi = \left[ \int_0^1 - \int_{-1}^0 \right] d\cos\theta_\pi \frac{d^3\Gamma}{dq^2 dm_{\pi\pi}^2 d\cos\theta_\pi} = \frac{\sqrt{3}}{2} (2 + \hat{m}_\ell^2) \text{Re}[A_0^0 A_1^*] + \frac{3\sqrt{3}}{2} \hat{m}_\ell^2 \text{Re}[A_0^0 A_1^*]. \]

(57)

We define the polarization fraction at a given value of \( q^2 \) and \( m_{\pi\pi}^2 \):

\[ \mathcal{F}_S(q^2, m_{\pi\pi}^2) = \frac{(1 + \hat{m}_\ell^2/2)|A_0^0|^2 + 3/2\hat{m}_\ell^2|A_1|^2}{d^2\Gamma/(dq^2 dm_{\pi\pi}^2)}, \]

(58)

\[ \mathcal{F}_P(q^2, m_{\pi\pi}^2) = \frac{(1 + \hat{m}_\ell^2/2)(|A_0^0|^2 + |A_1|^2 + |A_1^*|^2) + 3/2\hat{m}_\ell^2|A_1|^2}{d^2\Gamma/(dq^2 dm_{\pi\pi}^2)}, \]

and also

\[ \mathcal{F}_L(q^2, m_{\pi\pi}^2) = \frac{\sqrt{3}/2(2 + \hat{m}_\ell^2)|A_0^0 A_1^*| + 3\sqrt{3}/2\hat{m}_\ell^2 \text{Re}[A_0^0 A_1^*]}{d^2\Gamma/(dq^2 dm_{\pi\pi}^2)}. \]

(59)

By definition, \( \mathcal{F}_S + \mathcal{F}_P = 1 \).

In Fig. 6 we give our results for the S-wave fraction \( \langle F_S \rangle \) (panel (a)), longitudinal polarization fraction \( \langle F_L \rangle \) in P-wave contributions (panel (b)) and the asymmetry \( \langle A_{FB} \rangle \) (panel (c)). Only the curves for the light lepton \( \ell \) are shown since the results for the \( \mu \) lepton are similar. These observables and the following ones are defined by the integration over \( m_{\pi\pi}^2 \), for instance,

\[ \langle F_S(q^2) \rangle = \frac{\int dm_{\pi\pi}^2 (1 + \hat{m}_\ell^2/2)|A_0^0|^2 + 3/2\hat{m}_\ell^2|A_1|^2}{\int dm_{\pi\pi}^2 d^2\Gamma/(dq^2 dm_{\pi\pi}^2)}, \]

(60)

and likewise for the others.
The forward–backward asymmetry is defined as

$$A_{FB}^l \equiv \frac{d\Gamma}{dq^2 dm^2_{\pi\pi} d\cos\theta_t}.$$

C. Distribution in $\theta_t$ and forward–backward asymmetry

Integrating over $\theta_{\pi^+}$ and $\phi$, we have the distribution:

$$\frac{d^3\Gamma}{dq^2 dm^2_{\pi\pi} d\cos\theta_t} = \frac{3\pi}{4} \int d\cos\theta_{\pi^+} (I_1 + I_2 \cos(2\theta_i) + I_0 \cos\theta_i)$$

$$= \frac{3}{4} m_t^2 ((|A^0|^2 + |A^1|^2)) + \frac{3}{2} \cos\theta_i (Re[A^0_\| A^1_\|] + \hat{m}_t^2 Re[A^0_\| A^0_\| + A^1_\| A^1_\|])$$

$$+ \frac{3}{4} [1 - (1 - \hat{m}_t^2) \cos^2\theta_i] (|A^0_\||^2 + |A^1_\||^2) + \frac{3}{8} [(1 + \hat{m}_t^2) + (1 - \hat{m}_t^2) \cos^2\theta_i] (|A^1_\perp|^2 + |A^1_\|^2).$$

The forward–backward asymmetry is defined as

$$A_{FB}^l = \left[ \int_0^1 - \int_{-1}^0 \right] d\cos\theta_t \frac{d^3\Gamma}{dq^2 dm^2_{\pi\pi} d\cos\theta_t} = \frac{3}{2} (Re[A^0_\| A^1_\|] + \hat{m}_t^2 Re[A^0_\| A^0_\| + A^1_\| A^1_\|]),$$

and the results for $A_{FB}^l$ are given in Fig. 7.

D. Distribution in the azimuth angle $\phi$

The angular distribution in $\phi$ is derived as

$$\frac{d^3\Gamma}{dq^2 dm^2_{\pi\pi} d\phi} = a_\phi + b_\phi^c \cos\phi + b_\phi^s \sin\phi + c_\phi^c \cos(2\phi) + c_\phi^s \sin(2\phi)$$

with

$$a_\phi = \frac{1}{2\pi} \frac{d^2\Gamma}{dq^2 dm^2_{\pi\pi}},$$

$$b_\phi^c = \frac{3}{16} \pi \int I_5 d\cos\theta_{\pi^+} = \frac{3\sqrt{3}}{32\sqrt{2}\pi} (Re[A^0_\| A^1_\|] - \hat{m}_t^2 Re[A^0_\| A^1_\|])$$

$$b_\phi^s = \frac{3}{16} \pi \int I_7 d\cos\theta_{\pi^+} = \frac{3\sqrt{3}}{32\sqrt{2}\pi} (Im[A^0_\| A^1_\|] - \hat{m}_t^2 Im[A^0_\| A^1_\|])$$

$$c_\phi^c = \frac{1}{2} \int I_3 d\cos\theta_{\pi^+} = \frac{1}{4\pi} \beta_i (|A^1_\|^2 - |A^1_\|^2), \quad c_\phi^s = \frac{1}{2} \int I_9 d\cos\theta_{\pi^+} = \frac{1}{2\pi} \beta_i Im[A^1_\perp A^1_\|^*].$$

Since the complex phase in the P-wave amplitudes comes from the Breit–Wigner lineshape, the coefficient $c_\phi^s$ vanishes.
FIG. 8: Same as Fig. 5 but for the normalized coefficients in the $\phi$ distributions of the $D^- \to \pi^+ \pi^- \bar{\ell} \nu_{\ell}$. The left panels (a, c, e) are for the light lepton $e$, while the right panels (b, d, f) are for the $\mu$ lepton.

Numerical results for the normalized coefficients using the two sets of form factors are shown in Fig. 8. The coefficients $b_{c \phi}$ and $b_{s \phi}$ contain a very small prefactor, $3\sqrt{3}/(32\sqrt{2}\pi) \sim 0.037$, and thus are numerically tiny, as shown in this figure. The $c_{c \phi}$ is also small due to the cancellation between the $|A_\perp|^2$ and $|A_\parallel|^2$. 
Theoretical uncertainties in this analysis. The parametric errors in heavy-to-light transition form factors and QCD condensate parameter $B_0$ have been included in the above. As one can see, these uncertainties are sizable to branching fractions and other related observables, but are negligible in the ratios like $R^{\mu/e}_{\pi\pi}$. This is understandable, since most uncertainties will cancel in the ratio.
For the heavy-to-light form factors, we have used the LCSR and LFQM results. In LCSR, the theoretical accuracy for most form factors is at leading order in $\alpha_s$. An analysis of $B_s \to f_0$ [26] has indicated the NLO radiative corrections to form factors may reach 20%. The radiative corrections are, in general, channel-dependent but should be calculated in a high precision study. It should be pointed out that radiative corrections in the light-front quark model is not controllable.

A third type of uncertainties resides in the scalar $\pi\pi$ form factor. In this work, we have used the unitarized results from Refs. [44, 45], where the low-energy constants $(L_i, s)$ are obtained by fitting the $J/\psi$ decay data. A Muskhelishvili–Omnès formalism has been developed for the scalar $\pi\pi$ form factor in Ref. [18]. Compared to the results in Ref. [18], we find an overall agreement in the shape of the non-strange $\pi\pi$ form factor, but the modulus from Ref. [18] is about 20% larger. This would induce about 40% uncertainties to the branching ratios of the $D \to \pi\pi\ell\bar{\nu}_\ell$, while the results for the ratio observables are not affected.

Finally, the Watson theorem does not always guarantee the use of Eq. (9), the matching of $D \to \pi\pi$ form factor and $D \to f_0$ form factors. As we have discussed in Sec. II, such an approximation might be improved in the future.

IV. CONCLUSIONS

In summary, we have presented a theoretical analysis of the $D^- \to \pi^+\pi^-\ell\bar{\nu}$ and $\bar{D}^0 \to \pi^+\pi^0\ell\bar{\nu}$ decays. We have constructed a general angular distribution which can include arbitrary partial waves of $\pi\pi$. Retaining the S-wave and P-wave contributions we have studied the branching ratios, forward–backward asymmetries and a few other observables. The P-wave contribution is dominated by $\rho^0$, and the S-wave contribution is analyzed using the unitarized chiral perturbation theory. The obtained branching fraction for $D \to \rho\ell\nu$, at the order $10^{-3}$, is consistent with the available experimental data, while the S-wave contribution is found to have a branching ratio at the order of $10^{-4}$, and this prediction can be tested by experiments like BESIII and LHCb. The BESIII collaboration has accumulated about $10^7$ events of the $D^0$ and will collect about 3 fb$^{-1}$ data at the center-of-mass $\sqrt{s} = 4.17$ GeV to produce the $D_s^+D_s^-$ [51, 52]. All these data can be used to study the charm decays into the $f_0$ mesons. In addition, sizable branching fractions also indicate a promising prospect at the ongoing LHC experiment [53], the forthcoming Super-KEKB factory [54] and the under-design Super Tau-Charm factory. Future measurements can be used to study the $\pi-\pi$ scattering phase shift.

Appendix A: Angular coefficients

In the angular distribution, the coefficients have the form

\begin{align}
I_1 &= (1 + \hat{m}_l^2)|A_0|^2 + 2\hat{m}_l^2|A_i|^2 + (3 + \hat{m}_l^2)/2(|A_\perp|^2 + |A_i|^2), \\
I_2 &= -\beta_l|A_0|^2 + \beta_l/2(|A_\perp|^2 + |A_i|^2), \\
I_3 &= \beta_l(|A_\perp|^2 - |A_i|^2), \\
I_4 &= 2\beta_l|\text{Re}(A_0A_i^*)|, \\
I_5 &= 4|\text{Re}(A_0A_i^*) - \hat{m}_l^2\text{Re}(A_iA_0^*)|, \\
I_6 &= 4|\text{Re}(A_||A_i^*) + \hat{m}_l^2\text{Re}(A_iA_0^*)|, \\
I_7 &= 4|\text{Im}(A_0A_i^*) - \hat{m}_l^2\text{Im}(A_iA_0^*)|, \\
I_8 &= 2\beta_l|\text{Im}(A_0A_i^*)|, \\
I_9 &= 2\beta_l|\text{Im}(A_\perpA_i^*)|. \quad (11)
\end{align}
Substituting the expressions for $A_i$ into the above equation, we obtain the general expressions

$$I_1(q^2, m_{\pi\pi}^2, \theta_{\pi\pi}) = \sum_{J=0, \ldots} \left\{ |Y_{J}^0(\theta_{\pi\pi}, 0)|^2 \left[ (1 + \hat{m}_i^2) |A_0^J|^2 + 2 \hat{m}_i^2 |A_1^J|^2 \right] ight.$$

$$+ 2 \sum_{J'=J+1, \ldots} |Y_{J'}^0(\theta_{\pi\pi}, 0) Y_{J}^0(\theta_{\pi\pi}, 0) \left[ \cos(\delta_0^J - \delta_0^{J'}) |A_0^J| |A_0^{J'}*| + 2 \hat{m}_i^2 \cos(\delta_0^J - \delta_0^{J'}) |A_1^J| |A_1^{J'}*| \right] \right\},$$

$$\sum_{J'=J+1, \ldots} \left\{ |Y_{J'}^{-1}(\theta_{\pi\pi}, 0)|^2 \left[ |A_1^J|^2 + |A_1^{J'}|^2 \right] \right\},$$

$$+ \sum_{J'=J+1, \ldots} Y_{J'}^{-1}(\theta_{\pi\pi}, 0) Y_{J}^{-1}(\theta_{\pi\pi}, 0) \left[ 2 \cos(\delta_1^J - \delta_1^{J'}) |A_1^J| |A_1^{J'}*| \right], \quad (A2)$$

$$I_2(q^2, m_{\pi\pi}^2, \theta_{\pi\pi}) = -\beta_l \sum_{J=0, \ldots} \left\{ |Y_{J}^0(\theta_{\pi\pi}, 0)|^2 \left[ (1 + \hat{m}_i^2) |A_0^J| |A_0^{J'}*| \right] \right.$$
