The taming of recurrences in computability logic through cirquent calculus, Part II

Giorgi Japaridze

Abstract

This paper constructs a cirquent calculus system and proves its soundness and completeness with respect to the semantics of computability logic. The logical vocabulary of the system consists of negation ¬, parallel conjunction ∧, parallel disjunction ∨, branching recurrence ◦, and branching corecurrence ??. The article is published in two parts, with (the previous) Part I containing preliminaries and a soundness proof, and (the present) Part II containing a completeness proof.

MSC: primary: 03B47; secondary: 03B70; 68Q10; 68T27; 68T15.

Keywords: Computability logic; Cirquent calculus; Interactive computation; Game semantics; Resource semantics.

1 Outline

Being a continuation of [11], this article fully relies on the terminology and notation introduced in its predecessor, with which — or, at least, with the first six sections of which — the reader is assumed to be already familiar, and which is necessary to have at hand for references while reading this paper.

The purpose of the present piece of writing is to prove the completeness of CL15, in the form of clauses (b) and (c) of Theorem 6 of [11]. For the rest of this paper, we fix an arbitrary formula F_0 and assume that

CL15 ⊬ F_0. \hspace{1cm} (1)

Our immediate and most challenging goal, to which Sections 2-11 are devoted, is to prove that F_0 is not uniformly valid. The final Section 12 will then relatively painlessly extend this result from uniform to multiform (in)validity.

We are going to show that there is a counterstrategy (in fact, an effective one) E such that, when the environment plays according to E, no HPM wins F_0 \ast for an appropriately selected constant interpretation \ast. Of course, we have never defined the concept of an environment’s effective strategy. As explained in the following section, the latter, just like a machine’s strategy, can be understood simply as an EPM.

2 Machines against machines

Here we borrow a discussion from [2]. For a run Γ and a computation branch B of an EPM, we say that B cospells Γ iff B spells ¬Γ (Γ with all labels reversed) in the sense of Section 2.5 of [11]. Intuitively, when an EPM E plays as \bot rather than \top, the run that is generated by a given computation branch B of E is the run cospelled rather than spelled by B, for the moves that E makes get the label \bot, and the moves that its adversary makes get the label \top.

We say that an EPM E is fair iff, for every valuation e, every e-computation branch of E is fair (again, “fair branch” in the sense of Section 2.5 of [11]).
Lemma 2.1 Assume $E$ is a fair EPM, $H$ is an HPM, and $e$ is a valuation. There are a uniquely defined $e$-computation branch $B_E$ of $E$ and a uniquely defined $e$-computation branch $B_H$ of $H$ — which we respectively call the $(E, e, H)$-branch and the $(H, e, E)$-branch — such that the run spelled by $B_H$, called the $H$ vs. $E$ run on $e$, is the run cospelled by $B_E$.

When $H, E, e$ are as above, $\Gamma$ is the $H$ vs. $E$ run on $e$ and $A$ is a game such that $\Gamma$ is a $\top$-won (resp. $\bot$-won) run of $e[A]$, we say that $H$ wins (resp. loses) $A$ against $E$ on $e$. Simply saying “$H$ wins (resp. loses) $A$ against $E$” means that $H$ wins (resp. loses) $A$ against $E$ on some valuation $e$.

A strict proof of the above lemma can be found in [1] (Lemma 20.4), and we will not reproduce the formal proof here. Instead, the following intuitive explanation should suffice:

Proof idea. Assume $H, E, e$ are as in Lemma 2.1. The scenario that we are going to describe is the unique play generated when the two machines compete against each other, with $H$ in the role of $\top$, $E$ in the role of $\bot$, and $e$ spelled on the valuation tapes of both machines. We can visualize this play as follows. Most of the time during the process $H$ remains inactive (sleeping); it is woken up only when $E$ enters a permission state, on which event $H$ makes a (one single) transition to its next computation step — that may or may not result in making a move — and goes back into a sleep that will continue until $E$ enters a permission state again, and so on. From $E$’s perspective, $H$ acts as a patient adversary who makes one or zero move only when granted permission, just as the EPM-model assumes. And from $H$’s perspective, which, like a person in a coma, has no sense of time during its sleep and hence can think that the wake-up events that it calls the beginning of a clock cycle happen at a constant rate, $E$ acts as an adversary who can make any finite number of moves during a clock cycle (i.e. while $H$ was sleeping), just as the HPM-model assumes. This scenario uniquely determines an $e$-computation branch $B_E$ of $E$ that we call the $(E, e, H)$-branch, and an $e$-computation branch $B_H$ of $H$ that we call the $(H, e, E)$-branch. What we call the $H$ vs. $E$ run on $e$ is the run generated in this play. In particular — since we let $H$ play in the role of $\top$ — this is the run spelled by $B_H$. $E$, who plays in the role of $\bot$, sees the same run, only it sees the labels of the moves of that run in negative colors. That is, $B_E$ cospells rather than spells that run. This is exactly what Lemma 2.1 asserts.

3 Enumeration games

We continue identifying natural numbers with their decimal representations.

An enumeration game is a game in every instance of which any natural number $a$ is a legal move by either player $\varphi$ at any time, and there are no other legal moves. Either player can thus be seen to be enumerating a set of numbers — the numbers made by it as moves during the play. The winner in a (legal) play of a given instance of an enumeration game only depends on the two sets enumerated this way. That is, it only matters what moves have been eventually made, regardless of when (in what order) and how many times (only once or repetitively) those moves were made.

Since the order of moves is irrelevant, it is obvious that every enumeration game is static, and hence is a legitimate value of an interpretation * on any atom. We call an interpretation * that sends every atom $P$ to an enumeration game $P^*$ an enumeration interpretation. From now on, we will limit our considerations only to enumeration interpretations. Note that, under this restriction, the set of legal runs of $e[F_0]$ does not depend on the valuation $e$ or the interpretation *, because all instances of all enumeration games have the same set of legal runs. In view of this fact, we may safely talk about legal moves or runs of $e[F_0]$ even without having yet defined the interpretation * and/or without having specified the valuation $e$. Furthermore, as was done in [11], in many contexts we shall terminologically and notationally identify $F_0$ or any other formula or cirquent with the game into which it turns after a constant enumeration interpretation * is applied to it.

4 Units, funits and prompts

In what follows, “formula”, “atom” and “literal” always mean those of $F_0$. Extending the usage of the prefix “o” introduced in Definition 3.1 of [11], by an osubformula of a given formula $E$ we mean
a subformula of $E$ together with a fixed occurrence of it within $E$. Similarly for oliterals. Whenever we simply say “oformula”, unless otherwise specified or implied by the context, we always mean an osubformula of $\mathbb{F}_0$. We say that an oformula $E$ is an osuperformula of an oformula $G$ of iff $G$ is an osubformula of $E$. $E$ is a proper osuperformula (resp. osubformula) of $G$ iff $E$ is an osuperformula (resp. osubformula) of $G$ but not vice versa.

A politeral (“positive oliteral”) is an oliteral that is not in the scope of $\neg$. In other words, this is a positive occurrence of a literal. For instance, the formula $P \land (\neg Q \lor \neg R)$ has three (rather than five) politerals, which are $P$, the first occurrence of $\neg Q$, and the second occurrence of $\neg Q$.

The modal depth of an oformula $G$ is the number of the proper osuperformulas of $G$ of the form $\diamond E$ or $\lozenge E$.

A unit is a pair $(E, \vec{x})$, which we prefer to write as $E[\vec{x}]$, where $E$ is an oformula and $\vec{x}$ is an array (sequence) of as many infinite bitstrings as the modal depth of $E$ (if the latter is 0, then $E[\vec{x}]$ simply looks like $E[]$). Below is an inductive (re)definition of the set of units, together with the functional parenthood relation on units, and the projection function that takes a unit, a run $\Omega$ and returns a run:

(a) $\mathbb{F}_0[]$ is a unit, and the projection of $\Omega$ on $\mathbb{F}_0[]$ is $\Omega$ itself. The unit $\mathbb{F}_0[]$ has no parents.

(b) Assume $E[\vec{x}]$ is a unit, and $\Theta$ is the projection of $\Omega$ on it. Then:

1. Suppose $E$ is $G_0 \land G_1$ or $G_0 \lor G_1$. Then, for either $i \in \{0, 1\}$, $G_i[\vec{x}]$ is a unit, the projection of $\Omega$ on $G_i[\vec{x}]$ is $\Theta^i$ (see Notation 2.2 of [11]), and the (only) parent of $G_i[\vec{x}]$ is $E[\vec{x}]$.

2. Suppose $E$ is $\diamond G$ or $\lozenge G$. Then, for any finite bitstring $y$, $G[\vec{x}, y]$ is a unit, the projection of $\Omega$ on $G[\vec{x}, y]$ is $\Theta^\infty y$ (see Notation 2.2 of [11]), and the (only) parent of $G[\vec{x}, y]$ is $E[\vec{x}]$.

(c) Nothing is a unit unless it can be obtained by repeated application of (a) and (b).

A funit (“F” for “finite”) is a pair $(E, \vec{w})$, which we prefer to write as $E[\vec{w}]$, where $E$ is an oformula and $\vec{w}$ is a sequence of as many infinite bitstrings as the modal depth of $E$. Below is an inductive (re)definition of the set of funits, together with the parenthood relation on funits, as well as the address function that takes a funit and returns a string of bits and periods:

(a) $\mathbb{F}_0[]$ is a funit, and its address (as a string) is empty. This funit has no parents.

(b) Assume $E[\vec{w}]$ is a funit, and its address is $\alpha$. Then:

1. Suppose $E$ is $G_0 \land G_1$ or $G_0 \lor G_1$. Then, for either $i \in \{0, 1\}$, $G_i[\vec{w}]$ is a funit, and its address is $\alpha i$. ($\alpha$ followed by the bit $i$ followed by a period). The (only) parent of $G_i[\vec{w}]$ is $E[\vec{w}]$.

2. Suppose $E$ is $\diamond G$ or $\lozenge G$. Then, for any finite bitstring $u$, $G[\vec{w}, u]$ is a funit, and its address is $\alpha u$. ($\alpha$ followed by the bitstring $u$ followed by a period). The (only) parent of $G[\vec{w}, u]$ is $E[\vec{w}]$.

(c) Nothing is a funit unless it can be obtained by repeated application of (a) and (b).

When $E[\vec{x}] = E[x_1, \ldots, x_n]$ is a unit and $E[\vec{u}] = E[w_1, \ldots, w_n]$ is a funit such that $w_1 \preceq x_1, \ldots, w_n \preceq x_n$ we say that $E[\vec{u}]$ is a funital restriction of $E[\vec{x}]$, and that $E[\vec{x}]$ is a unital extension of $E[\vec{u}]$.

A politeral unit (resp. politeral funit) is a unit (resp. funit) $L[\vec{x}]$ such that $L$ is a politeral.

We say that a unit $E[\vec{x}]$ is a child of a unit $G[\vec{y}]$ iff $G[\vec{y}]$ is the parent of $E[\vec{x}]$. We say that $E[\vec{x}]$ is a subunit of $G[\vec{y}]$, and that $G[\vec{y}]$ is a superunit of $E[\vec{x}]$, iff $E[\vec{x}] = G[\vec{y}]$, or $E[\vec{x}]$ is a child of $G[\vec{y}]$, or $E[\vec{x}]$ is a child of a child of $G[\vec{y}]$, or . . . . Such a subunit or superunit is said to be proper iff $G[\vec{y}] \neq E[\vec{x}]$. Similarly for funits instead of units.

We agree that, when $E[\vec{w}]$ is a funit and $\beta$ is a move, by “making the move $\beta$ in $E[\vec{w}]$” we mean making the move $\alpha \beta$, where $\alpha$ is the address of $E[\vec{w}]$. When $E[\vec{x}]$ is a unit and $\beta$ is a move, by “making the move $\beta$ in $E[\vec{x}]$” we mean making the move $\beta$ in some funital restriction of $E[\vec{x}]$. If here $\beta$ is a

\footnote{Remember that, as we agreed earlier, $w \preceq x$ means that $w$ is a prefix of $x$.}
decimal numeral, we say that it is a **numeric move**. Note that numeric moves can be legally made only in politeral (f)units.

Intuitively, a legal play/run $\Omega$ of $F_0$ comprises parallel plays in all of the politeral units. Namely, the run that is taking place in a politeral unit $L[x]$ is nothing but the projection of $\Omega$ on $L[x]$. Every move of $\Omega$ has the form $\alpha a$, where $a$ is a decimal numeral, and $\alpha$ is the address of some politeral unit $L[x]$. The intuitive and technical effect of such a move is making the numeric move $a$ in all politeral units $L[x]$ that happen to be unital extensions of $L[w]$.

We define the **height** $h$ of a funit $E[w_1, \ldots, w_n]$ as the length of a longest bitstring among $w_1, \ldots, w_1$ (here, if $n = 0$, we let $h = 0$). We say that a funit $E[w_1, \ldots, w_n]$ is regular iff all of the bitstrings $w_1, \ldots, w_n$ are of the same length.

Let $\Phi$ be a position. By a **$\Phi$-active funit** we mean a funit $G[\vec{u}]$ such that $\Phi$ contains some move made by either player in $G[\vec{u}]$ (that is, $\Phi$ contains some labmove of the form $\varphi \alpha \beta$, where $\varphi \in \set{\top, \bot}$ and $\alpha$ is the address of $G[\vec{u}]$). And by a **$\Phi$-prompt** we mean any of the (finitely many) regular politeral funits $L[\vec{w}]$ such that

- either $\vec{w}$ is empty ($L$ is not in the scope of any occurrences of $\bot$ and/or $\top$ within $F_0$, that is),
- or $L[\vec{w}]$ is of height $h$, where $h$ is the smallest number exceeding the heights of all $\Phi$-active funits.

## 5 The counterstrategy $\mathcal{E}$

Technically, the counterstrategy $\mathcal{E}$ that we are going to construct in this section is an EPM, meaning that, in a computation branch of $\mathcal{E}$, the moves made by $\mathcal{E}$ appear (as they should according to our definition of an EPM given in Section 2.5 of [11]) on the run tape of $\mathcal{E}$ with the label $\top$, and the moves made by its adversary with the label $\bot$. However, we will be eventually interested in the runs cospelled rather than spelled by computation branches of $\mathcal{E}$. Correspondingly, when describing or analyzing the work of $\mathcal{E}$, it is beneficial for our intuition to directly talk about the positions “cospelled” rather than spelled on the run tape of the machine at various times. Namely, we agree that, in the context of any step of any play (computation branch) of $\mathcal{E}$, by the **current position** we mean $\neg \Psi$, where $\Psi$ is the position spelled on the run tape of $\mathcal{E}$.

We define $\mathcal{E}$ as an EPM that creates a variable $i$, initializes its value to 1, and then keeps performing the following routine forever: at every step of (our description of) the latter, $\Phi$ refers to the then-current position of the play:

**ROUTINE**: Let $L_1[\vec{w}_1], \ldots, L_n[\vec{w}_n]$ be the lexicographic list of all $\Phi$-prompts.

1. Do the following while $i \leq n$:
   a. Make the numeric move $a$ in $L_i[\vec{w}_i]$, where $a$ is the smallest natural number never made as a numeric move in whatever politeral unit by either player so far in the play (in $\Phi$, that is). Then increment $i$ to $i + 1$.

2. Once $i$ becomes $n + 1$, reset it to 1, grant permission, and repeat ROUTINE.

Note that $\mathcal{E}$ is a fair EPM, so that Lemma [24] applies. This is so because $\mathcal{E}$ repeats ROUTINE infinitely many times, and each repetition grants permission.

Also take a note of the fact that

\[ \mathcal{E} \text{ always makes “fresh” numeric moves,} \]

in the sense that it never makes a numeric move (in whatever politeral unit) that has already been made in the play (in whatever politeral unit) by either player.

We now pick an arbitrary valuation $e$, an arbitrary HPM $\mathcal{H}$ and denote by $\Omega$ the $\mathcal{H}$ vs. $\mathcal{E}$ run on $e$, i.e., the run cospelled by the ($\mathcal{E}, e, \mathcal{H}$)-branch. We fix these parameters $e$, $\mathcal{H}$, $\Omega$ until further notice (in Section [22] and agree that our discourse is always in the context of these particular $e$, $\mathcal{H}$ and $\Omega$. So,

---

2Note that every iteration of this WHILE loop changes the value of $\Phi$. 

---
for instance, when we say “$E$ made the move $\alpha$ at time $t$”, it is to be understood as that such a move was made by $E$ in the $(E, e, H)$-branch on the $t$’th clock cycle. It is important to point out once again that, in such contexts, $E$ will be viewed as the “author” of $\bot$-labeled moves (in $\Omega$), and its adversary $H$ as the “author” of $\top$-labeled moves, because this is exactly how the corresponding moves are labeled in $\Omega$, which is the run cospelled (rather than spelled) by the $(E, e, H)$-branch that we are considering.

Notice that $E$ never makes illegal moves. We may safely pretend that neither does its adversary, for otherwise $E$ automatically wins and the case is trivial. So, we adopt the assumption that

$$
\Omega \text{ is a legal run of } \mathbb{F}_0,
$$

which, in view of our conventions of Section $\text{[4]}$ precisely means that, for any constant enumeration interpretation $^*$, $\Omega$ is a legal run of $\mathbb{F}_0^0$ — or, equivalently, that for any (not necessarily constant) enumeration interpretation $^*$, $\Omega$ is a legal run of $e[\mathbb{F}_0^0]$.

6 Unit trees, resolutions and driving

We have been using capital Latin letters as metavariables for formulas, oformulas and cirquents. In what follows, we use the same metavariables for units as well. When $E$ is used to denote a unit $G[\vec{x}]$, the latter (as an expression) is said to be the expanded form of the former. For a unit $E$, by the $F_0$-origin of $E$, symbolically

$$
\vec{E},
$$

we shall mean the oformula $G$ such that the expanded form of $E$ is $G[\vec{x}]$ for some $\vec{x}$. When $\vec{E} = G$ and $G$ has the form $\triangle H$, we may refer to $E$ (resp. $G$) as a $\triangle$-unit (resp. $\triangle$-oformula). Similarly in the case of other connectives instead of $\triangle$.

In the sequel we may refer to a unit as $\triangle E$ to indicate that it is a $\triangle$-unit. In such a case, the $F_0$-origin of $\triangle E$ will be denoted by $\triangle \vec{E}$. Similarly in the case of other connectives instead of $\triangle$.

By a unit tree we mean a nonempty set $S$ of units such that, whenever a unit $E$ is in $S$, we have:

- all superunits of $E$ are in $S$;
- if $E$ is a $\land$- or $\lor$-unit, then both of its children are in $S$;
- if $E$ is a $\top$- or $\bot$-unit, then at least one of its children is in $S$.

Note that every unit tree is indeed a tree of units formed by the parenthood relation, where the root is always the unit $\mathbb{F}_0[\cdot]$.

For unit trees we use the same metavariables as for formulas, oformulas, cirquents or units. The unit tree consisting of all units (the “biggest” unit tree) we denote by

$$
\mathbb{F}_1.
$$

It may be helpful for one’s intuition to think of $\mathbb{F}_1$ as (the parse tree of) a “formula” of finite height but infinite — in fact, uncountable — width. Such a “formula” is similar to $\mathbb{F}_0$, with the only difference that, while every $\bot$- or $\top$-osubformula of $\mathbb{F}_0$ has a single child, a corresponding “osubformula” (unit) of $\mathbb{F}_1$ has uncountably many children instead — one child per infinite bitstring.

When $F$ is a unit tree and $E$ is an element of $F$ other than the root, by trimming $F$ at $E$ we mean deleting from $F$ all subunits of $E$ (including $E$ itself).

A resolution is a function $A$ that sends each unit $\triangle E$ either to the value $A(\triangle E) = \text{Unresolved}$, or to an infinite bitstring $A(\triangle E) = x$. In the former case we say that $\triangle E$ is $A$-unresolved; in the latter case we say that $\triangle E$ is $A$-resolved and, where $A(\triangle E) = \vec{y}$, call the unit $\vec{E}[\vec{y}, x]$ the $A$-resolvent of $\triangle E$. When $A$ is fixed, we may omit it and simply say “resolved”, “resolvent” etc.

Intuitively, a resolution $A$ selects a single child — namely, the resolvent — for each $A$-resolved $\triangle$-unit, and does nothing for any other units. In accordance with this intuition, when $A$ is a resolution, we will be using the expression

$$
\mathbb{F}_1^A
$$
to denote the unit tree that is the result of trimming \( F_1 \) at every child of every \( \mathcal{A} \)-resolved \( \dagger \)-unit except the child which is the \( \mathcal{A} \)-resolvent of that unit.

The **trivial resolution**, which we denote by \( \emptyset \), is the one that returns the value **Unresolved** for every \( \dagger \)-unit. Thus, \( F_1 = F_1^\emptyset \).

On the other extreme, a resolution \( \mathcal{A} \) such that every \( \dagger \)-unit of \( F_1^\mathcal{A} \) is \( \mathcal{A} \)-resolved is said to be **total**.

We say that a resolution \( \mathcal{A}_2 \) is an extension of a resolution \( \mathcal{A}_1 \) iff every \( \mathcal{A}_1 \)-resolved \( \dagger \)-unit is also \( \mathcal{A}_2 \)-resolved (but not necessarily vice versa), and the \( \mathcal{A}_2 \)-resolvent of each such unit is the same as its \( \mathcal{A}_1 \)-resolvent.

We say that two resolutions \( \mathcal{A}_1 \) and \( \mathcal{A}_2 \) are **consistent** iff they agree on every \( \dagger \)-unit that is both \( \mathcal{A}_1 \)-resolved and \( \mathcal{A}_2 \)-resolved. Note that if one resolution is an extension of another, then the two resolutions are consistent.

Let \( S \) be a set of pairwise consistent consistent resolutions. Then the **union** of the resolutions from \( S \) is the “smallest” common extension \( \mathcal{R} \) of all elements of \( S \). Precisely, for any unit \( \dagger F, \dagger E \) is \( \mathcal{R} \)-resolved iff it is \( \mathcal{A}_\mathcal{R} \)-resolved for some \( \mathcal{A} \in S \), in which case \( \mathcal{R}(\dagger E) = \mathcal{A}(\dagger E) \). Note that if the set \( S \) is empty, such a resolution \( \mathcal{R} \) is trivial.

The **smallest common superunit** of units \( E \) and \( G \) is the unit \( H \) such that:

1. \( H \) is a superunit of both \( E \) and \( G \), i.e., is a **common superunit** of \( E \) and \( G \), and
2. \( H \) is a subunit of every common superunit of \( E \) and \( G \).

Note that any two units have a unique smallest common superunit.

**Definition 6.1** Below, \( E, G, H \) are arbitrary units, and \( \mathcal{A} \) is an arbitrary resolution.

1. We say that \( E \) **drives** \( G \) **through** \( H \) iff the following two conditions are satisfied:
   - \( H \) is the smallest common superunit of \( E \) and \( G \).
   - \( E \) has no proper \( \dagger \)-superunits that happen to be subunits of \( H \).
2. We say that \( E \) **\( \mathcal{A} \)-strictly drives** \( G \) **through** \( H \) iff \( E \) drives \( G \) through \( H \) and, in addition, the following condition is satisfied for any unit \( \dagger F \):
   - If \( \dagger F \) is a proper superunit of \( E \) that happens to be a subunit of \( H \), then \( \dagger F \) is \( \mathcal{A} \)-resolved and \( E \) is a subunit of its \( \mathcal{A} \)-resolvent.
3. When we simply say “\( E \) drives \( G \)”, it is to be understood as “\( E \) drives \( G \) through \( H \)” for some \( H \). Similarly for “\( E \) \( \mathcal{A} \)-strictly drives \( G \)”.

**Lemma 6.2** For every resolution \( \mathcal{A} \) and units \( E, G \), if \( G \) is a subunit of \( E \), then \( E \) \( \mathcal{A} \)-strictly drives \( G \) through \( E \).

**Proof.** Consider any resolution \( \mathcal{A} \) and units \( E, G \). If \( G \) is a subunit of \( E \), then \( E \) is the smallest common superunit of \( E \) and \( G \). Of course, \( E \) has no proper superunits that happen to be subunits of \( E \). So, \( E \) \( \mathcal{A} \)-strictly drives \( G \) through \( E \).  

**Lemma 6.3**

1. The relation “drives” is transitive. That is, for any units \( G_1, G_2, G_3 \), if \( G_1 \) drives \( G_2 \) and \( G_2 \) drives \( G_3 \), then \( G_1 \) drives \( G_3 \).
2. Similarly for “\( \mathcal{A} \)-strictly drives” (for whatever resolution \( \mathcal{A} \)).

**Proof.** Here we will only prove clause 1. Clause 2 can be verified in a rather similar way, and we leave this job (if necessary) to the reader.

Assume \( G_1, G_2, G_3 \) are units such that \( G_1 \) drives \( G_2 \) and \( G_2 \) drives \( G_3 \). Let \( H_{12} \) be the smallest common superunit of \( G_1 \) and \( G_2 \), and \( H_{23} \) be the smallest common superunit of \( G_2 \) and \( G_3 \). Thus, \( H_{12} \)
and $H_{23}$ have a common subunit (namely, $G_2$). Therefore, since $F_1$ is a tree, $H_{12}$ is either a superunit or a subunit of $H_{23}$.

If $H_{12}$ is a superunit of $H_{23}$, then $H_{12}$ is clearly the smallest common superunit of $G_1$ and $G_3$. We also know that, among the subunits of $H_{12}$, $G_1$ has no proper $?$-superunits. Thus, $G_1$ drives $G_3$ through $H_{12}$.

If $H_{12}$ is a subunit of $H_{23}$, then $H_{23}$ is clearly the smallest common superunit of $G_1$ and $G_3$. Note that, among the subunits of $H_{23}$, $H_{12}$ has no proper $?^\circ$-superunits, because then so would have $G_2$, meaning that $G_2$ does not drive $G_3$. At the same time, among the subunits of $H_{12}$, $G_1$ has no proper $?^\circ$-superunits. Thus, $G_1$ has no proper $?^\circ$-superunits that happen to be subunits of $H_{23}$, meaning that $G_1$ drives $G_3$ through $H_{23}$. ■

Lemma 6.4 For every resolution $A$ and unit $G$, the set of the units that $A$-strictly drive $G$ is finite. Furthermore, all units that $A$-strictly drive $G$ have different $F_0$-origins.

Proof. Consider an arbitrary resolution $A$ and an arbitrary unit $G$. Seeing $F_1$ as a downward-growing tree of units induced by the parenthood relation, every unit $E$ that $A$-strictly drives $G$ can be reached from $G$ by first going up the tree to the smallest common superunit $H$ of $E$ and $G$, and then descending to $E$, where $?$-units or $A$-unresolved $\bot$-units may occur (may be passed through) only during the upward journey, and where, whenever an $A$-resolved $\bot$-unit is passed through on the downward journey, the descend from there always happens to the $A$-resolvent of that unit. There are only finitely many upward journeys from $G$ (as many as the number of all superunits of $G$), and from each upward journey there are only finitely many downward journeys that satisfy the above conditions. Furthermore, to every upward-downward journey (sequence of units) $\bar{U}$ of the above kind obviously corresponds a unique upward-downward journey in the parse tree of $F_0$ — namely, the result of replacing every unit of $\bar{U}$ by its $F_0$-origin. With a moment’s thought, this can be seen to imply that the $F_0$-origin of the last unit of $\bar{U}$ is unique. ■

Lemma 6.5 For any units $E$, $G$ and resolutions $A$, $A'$, if $E$ $A$-strictly drives $G$ and $A'$ is an extension of $A$, then $E$ also $A'$-strictly drives $G$.

Proof. Rather immediate from the relevant definitions. ■

7 Visibility

We say that two politeral units $L$ and $M$ are opposite to each other iff $\tilde{L} = \neg \tilde{M}$ (which is the same as to say that $M = \neg \bar{L}$) and, for both $\varphi \in \{\top, \bot\}$, the set of all $\varphi$-labeled moves found in the projection of $\Omega$ (the run fixed in Section 5) on $L$ coincides with the set of all $\neg \varphi$-labeled moves found in the projection of $\Omega$ on $M$.

Lemma 7.1 Every politeral unit has at most one opposite politeral unit.

Proof. As observed in $[2]$, $E$ always makes fresh numeric moves. And it does so in regular funits of ever increasing heights. Therefore its is obvious that, if $M_1$ and $M_2$ are two different politeral units (and hence have no common regular funital restrictions of heights greater than a certain bound $h$), there is a numeric move (in fact, infinitely many numeric moves) made by $E$ in $M_1$ but not in $M_2$ (and vice versa, of course). That is, the set of the $\bot$-labeled moves found in the projection of $\Omega$ on $M_1$ is different from the set of the $\bot$-labeled moves found in the projection of $\Omega$ on $M_2$. For this reason, $M_1$ and $M_2$ cannot be simultaneously opposite to the same unit. To summarize, no politeral unit $L$ can have two different opposite (to $L$) politeral units $M_1$ and $M_2$. ■

3For the exception of funits of the form $E[\cdot]$, of course, whose height is always 0.
Definition 7.2 Let $\mathcal{A}$ be a resolution.

1. A visibility chain in $\mathcal{A}$ is a nonempty sequence

$$L_1, M_1, \ldots, L_n, M_n$$

of politeral units such that, for every $i$ with $1 \leq i \leq n$, the following holds:

(a) $L_i$ and $M_i$ are opposite to each other.

(b) If $i < n$, then $M_i$ $\mathcal{A}$-strictly drives $L_{i+1}$.

2. $L_1$ is said to be the head of chain (4), and $M_n$ is sad to be the tail.

3. The type of chain (4) is the sequence $\tilde{L}_1, \tilde{M}_1, \ldots, \tilde{L}_n, \tilde{M}_n$

resulting from (4) by replacing all units with their $F_0$-origins.

In what follows, by a visibility chaintype we mean any nonempty, even-length finite sequence of politerals of $F_0$. Thus, the type of every visibility chain is a visibility chaintype. Not every visibility chaintype can be the type of an actual visibility chain though, and the reason for introducing the term “visibility chaintype” is merely technical.

Lemma 7.3 There are only countably many visibility chaintypes.

Proof. This is so because $F_0$ only has finitely many politerals, and every visibility chaintype is a finite sequence of such politerals. $\blacksquare$

Lemma 7.4 For every visibility chaintype $\tilde{T}$, resolution $\mathcal{A}$ and politeral unit $J$, there is at most one $J$-tailed visibility chain in $\mathcal{A}$ of type $\tilde{T}$.

Proof. Consider any resolution $\mathcal{A}$, politeral unit $J$ and visibility chaintype

$$\tilde{T} = X_1, Y_1, \ldots, X_n, Y_n.$$ 

Assume the following are two $J$-tailed visibility chains in $\mathcal{A}$ of type $\tilde{T}$:

$$\tilde{N} = L_1, M_1, \ldots, L_n, M_n;$$

$$\tilde{N}' = L'_1, M'_1, \ldots, L'_n, M'_n.$$ 

We want to show that $\tilde{N} = \tilde{N}'$, that is, show that, for every $i \in \{1, \ldots, n\}$, $M_i = M'_i$ and $L_i = L'_i$.

Since both visibility chains are $J$-tailed, we have $M_n = M'_n = J$. This, in view of Lemma 7.1, immediately implies that we also have $L_n = L'_n$, because $L_n$ (resp. $L'_n$) and $M_n$ (resp. $M'_n$) are opposite.

Now consider the case $i = n - 1$ (the cases $i = n - 2$, $i = n - 3$, etc. will be handled similarly). Both $M_{n-1}$ and $M'_{n-1}$ 0-drive $L_n = L'_n$ in $\mathcal{A}$, and we also have $M_{n-1} = M'_{n-1} = Y_{n-1}$. Therefore, by the “Furthermore” clause of Lemma 6.4, $M_{n-1} = M'_{n-1}$. This, in turn, as in the previous case, immediately implies that $L_{n-1} = L'_{n-1}$. $\blacksquare$

Lemma 7.5 For every resolution $\mathcal{A}$ and politeral unit $J$, the following set is countable:

$$\{ I \mid I \text{ is a politeral unit such that there is a visibility chain in } \mathcal{A} \text{ with head } I \text{ and tail } J \}.$$ 

Proof. Immediately from Lemmas 7.3 and 7.4. $\blacksquare$
Definition 7.6 Let $A$ be a resolution, and $E$ and $G$ any units. We say that $E$ is **visible** to $G$ in $A$ iff either $E$ $A$-strictly drives $G$ or there is a visibility chain $\vec{N}$ in $A$ such that $E$ $A$-strictly drives the head of $\vec{N}$, and the tail of $\vec{N}$ $A$-strictly drives $G$.

Lemma 7.7 For every resolution $A$ and unit $G$, the set of the units that are visible to $G$ in $A$ is countable.

Proof. Immediately from Lemmas 6.4 and 7.5.

Lemma 7.8 Assume $A$ is a resolution, $E$ is a unit and $G$ is a subunit of $E$. Then:
1. $E$ is visible to $G$ in $A$.
2. For any unit $H$, if $G$ is visible to $H$ in $A$, then so is $E$.

Proof. Assume the conditions of the lemma. Below, “visible” means “visible in $A$”. Similarly for “visibility chain”.

Clause 1 is immediate from Lemma 6.2. For clause 2, assume $H$ is a unit such that $G$ is visible to $H$. If the reason for this visibility is that $G$ $A$-strictly drives $H$, then the same reason makes $E$ also visible to $H$, because, by Lemma 6.2 and clause 2 of Lemma 6.3 $E$ $A$-strictly drives $H$. Now assume the reason for $G$ being visible to $H$ is that there is a visibility chain $\vec{N}$ such that $G$ $A$-strictly drives the head of $\vec{N}$, and the tail of $\vec{N}$ $A$-strictly drives $H$. Then, again by Lemma 6.2 and clause 2 of Lemma 6.3 $E$ $A$-strictly drives the head of $\vec{N}$. Hence $E$ is visible to $H$.

Lemma 7.9 If a unit $E$ is visible to a unit $G$ in a resolution $A$, then $E$ remains visible to $G$ in all extensions of $A$ as well.

Proof. Immediately from Lemma 6.5.

8 Domination

Definition 8.1 Let $F$ be a unit tree, and $\diamond E, G \in F$. A $\diamond E$-over-$G$ domination chain in $F$ is a nonempty sequence $L_1, M_1, X_1, \ldots, L_n, M_n, X_n$ of units where, with $i$ ranging over $\{1, \ldots, n\}$ and $G$ renamed into $L_{n+1}$ for convenience, the following conditions are satisfied:
1. $L_i$ and $M_i$ are opposite politeral units of $F$.
2. $M_i$ drives $L_{i+1}$ through $X_i$.
3. $M_i$ does not drive any $L_j$ with $i + 2 \leq j \leq n + 1$.
4. $M_i$ is not a subunit of $\diamond E$.
5. $L_1$ is a subunit of $\diamond E$.

The **type** of such a domination chain is the sequence $\tilde{L}_1, \tilde{M}_1, \tilde{X}_1, \ldots, \tilde{L}_n, \tilde{M}_n, \tilde{X}_n$.

When we simply say “a domination chain”, it is to be understood as “a $\diamond E$-over-$G$ domination chain in $F$ for some (whatever) unit tree $F$ and units $\diamond E, G \in F$”.

By a domination chain **type** we shall mean any sequence of oformulas of $\mathbb{F}_0$ of length $3n$ for some positive integer $n$. 

Definition 8.2 Where $F$ is a unit tree and $\triangleleft E$ and $G$ are units, we say that $\triangleleft E$ dominates $G$ in $F$ iff $\triangleleft E, G \in F$ and either $G$ is a proper subunit of $\triangleleft E$ or there is a $\triangleleft E$-over-$G$ domination chain in $F$.

Lemma 8.3 For any unit tree $F$ and units $\triangleleft E, G, H$ of $F$, if $\triangleleft E$ dominates $G$ in $F$ and $H$ is a subunit of $G$, then $\triangleleft E$ also dominates $H$ in $F$.

Proof. Assume the conditions of the lemma. Below “dominates” should be understood as “dominates in $F$”. Similarly for “domination chain”.

If the reason for $\triangleleft E$ dominating $G$ is that $G$ is a proper subunit of $\triangleleft E$, then the same reason makes $\triangleleft E$ dominate $H$. Now assume the reason for $\triangleleft E$ dominating $G$ is that there is a $\triangleleft E$-over-$G$ domination chain

$$L_1, M_1, X_1, \ldots, L_n, M_n, X_n.$$ (5)

So, $M_n$ drives $G$. In view of Lemma 6.2, we also know that $G$ drives $H$. Hence, by clause 1 of Lemma 6.3, $M_n$ drives $H$. Thus, at least one of the units $M_1, \ldots, M_n$ drives $H$. Let $i$ be the smallest integer among 1, $\ldots$, $n$ such that $M_i$ drives $H$, and let $Y$ be the smallest common superunit of $M_i$ and $H$.

Then, obviously, the sequence

$$L_1, M_1, X_1, \ldots, L_{i-1}, M_{i-1}, X_{i-1}, L_i, M_i, Y$$

is a $\triangleleft E$-over-$H$ domination chain, so that $\triangleleft E$ dominates $H$. □

Lemma 8.4 Any two opposite politeral units of any unit tree $F$ are dominated (in $F$) by exactly the same $\triangleleft$-units of $F$.

Proof. Consider any unit tree $F$, any two opposite politeral units $L$ and $M$ of $F$, any unit $\triangleleft E$ of $F$ and assume that $\triangleleft E$ dominates $L$, with “dominates” here and below meaning “dominates in $F$”, and similarly for “domination chain”. Our goal to show that $\triangleleft E$ also dominates $M$.

If $M$ is a subunit of $\triangleleft E$, then it is so in the proper sense, so $\triangleleft E$ dominates $M$. Otherwise, if $L$ is a subunit of $\triangleleft E$, then obviously the three-element sequence $L, M, M$ is a $\triangleleft E$-over-$M$ domination chain and, again, $\triangleleft E$ dominates $M$. Now, for the rest of this proof, assume neither $M$ nor $L$ is a subunit of $\triangleleft E$.

Let

$$L_1, M_1, X_1, \ldots, L_n, M_n, X_n$$

be a $\triangleleft E$-over-$L$ domination chain. Thus, $M_n$ drives $L$. If one of the units $M_1, \ldots, M_n$ drives $M$, then, where $M_i$ is the leftmost of such units and $Y$ is the smallest common superunit of $M_i$ and $M$, the following sequence is obviously a $\triangleleft E$-over-$M$ domination chain:

$$L_1, M_1, X_1, \ldots, L_{i-1}, M_{i-1}, X_{i-1}, L_i, M_i, Y.$$ 

And if none of the units $M_1, \ldots, M_n$ drives $M$, then the sequence

$$L_1, M_1, X_1, \ldots, L_n, M_n, X_n, L, M, M$$

is a $\triangleleft E$-over-$M$ domination chain. In either case we thus have that $\triangleleft E$ dominates $M$, as desired. □

Lemma 8.5 Assume $F$ is a unit tree, and $\triangleleft E, G, G'$ are units of $F$ such that $\triangleleft E$ dominates $G$ in $F$ and $G'$ is the parent of $G$. Then we have:

(a) If $G'$ is a $\wedge$- or $\lor$-unit, then $\triangleleft E$ dominates $G'$ in $F$.

(b) If $G'$ is a $\triangleleft$-unit, then either $\triangleleft E = G'$ or $\triangleleft E$ dominates $G'$ in $F$.  

10
Proof. Assume the conditions of the lemma. In what follows, “dominates” and “domination chain” should be understood in the context of $F$.

Clause (a): Assume $G'$ is a $\wedge$- or $\lor$-unit. If the reason for $\delta E$ dominating $G$ is that $G$ is a proper subunit of $\delta E$, then obviously $G'$ is also a proper subunit of $\delta E$ and is thus also dominated by the latter. Suppose now the reason for $\delta E$ dominating $G$ is that there is a $\delta E$-over-$G$ domination chain

$$L_1, M_1, X_1, \ldots, L_n, M_n, X_n.$$ 

Let $Y$ be $X_n$ if the latter is a superunit of $G'$, and be $G'$ otherwise. In other words, $Y$ is the smallest common superunit of $X_n$ and $G'$. As such, $Y$ is also the smallest common superunit of $M_n$ and $G'$. Further, obviously $M_n$ has no $?\,$-superunit that happens to be a subunit of $Y$. Thus, $M_n$ drives $G'$. Further, no $Mi$ with $1 \leq i < n$ drives $G'$, for otherwise, in view of Lemma 6.2 $Mi$ would also drive $G$. To summarize, $\delta E$ dominates $G'$ because the following is a $\delta E$-over-$G'$ domination chain:

$$L_1, M_1, X_1, \ldots, L_n, M_n, Y.$$ 

Clause (b): Assume $G'$ is a $\delta$-unit. If the reason for $\delta E$ dominating $G$ is that the latter is a proper subunit of the former, then it is clear that either $\delta E = G'$, or $G'$ is a proper subunit of $\delta E$ and hence is dominated by $\delta E$. And if the reason for $\delta E$ dominating $G$ is that there is a $\delta E$-over-$G$ domination chain, we use an argument similar to the one employed in the proof of clause (a) and, again, find that $\delta E$ dominates $G'$.

9 Main lemma

Lemma 9.1 There is a total resolution $T$ such that, with “dominates” meaning “dominates in $F^T_1$”, the following conditions are satisfied:

(i) No $\delta$-unit of $F^T_1$ dominates the root of $F^T_1$.

(ii) The relation of domination on $F^T_1$ is asymmetric. That is, no two (not necessarily distinct) $\delta$-units of $F^T_1$ dominate each other.

(iii) The relation of domination on $F^T_1$ is transitive. That is, for any units $\delta E$, $\delta G$, $H$ of $F^T_1$, if $\delta E$ dominates $\delta G$ and $\delta G$ dominates $H$, then $\delta E$ dominates $H$.

The rest of this fairly long section is exclusively devoted to a proof of the above lemma. Throughout that proof, we assume that $F_0$ is not $\delta$-free, for otherwise the lemma holds trivially — there are no $\delta$-units to dominate anything.

9.1 Pruning and pillaring

We agree that a pruner means a set $S$ of finite bitstrings containing the empty string $\epsilon$ and satisfying the condition that, whenever $u$ is a prefix of some string of $S$, there is an extension $v$ of $u$ (i.e. $u \preceq v$) such that both $v0$ and $v1$ are in $S$. The shortest of such extensions $v$ of $u$ (possibly $v = u$) is denoted by $\langle u \rangle^S$, which can simply be written as $[u]$ when $S$ is fixed in a context.

Next, when $S$ is a pruner, the limit set of $S$, denoted by $\text{LIM}(S)$, is the set of all infinite bitstrings $x$ such that there are infinitely many elements $w$ of $S$ with $w \preceq x$. Thus, where $w_1, w_2, w_3, \ldots$ are all such elements of $S$ listed according to their lengths, we have

$$w_1 \preceq w_2 \preceq w_3 \preceq \ldots \preceq x.$$ 

4Remember that the root of $F^T_1$, just as the root of any other unit tree, is nothing but the unit $F_0[.]$.
This explains the word “limit” in the name of $\text{Lim}(S)$: every element of $\text{Lim}(S)$ is the limit of an above kind of a series of elements of $S$.

It is obvious that, for every pruner $S$, $\text{Lim}(S)$ has a continuum of elements: there is a straightforward one-to-one mapping from the set $2^{\omega}$ of all infinite bitstrings to $\text{Lim}(S)$. Namely, to any element $b_1b_2b_3\ldots$ (each $b_i$ is either 0 or 1) of $2^{\omega}$ corresponds the element of $\text{Lim}(S)$ whose initial segments are

$$\epsilon, \ [\epsilon]Sb_1, \ [[\epsilon]Sb_1]Sb_2, \ [[[\epsilon]Sb_1]Sb_2]Sb_3, \ \ldots$$

(remember that $\epsilon$ is the empty bitstring).

Now, we define a pruning as a function $B$ that sends every unit $\downarrow E$ to some pruner, which (the pruner) is denoted by $B(\downarrow E)$.

When $A$ is a resolution and $B$ is a pruning, the expression

$$F_1^{AB}$$

denotes the unit tree that is the result of trimming $F_1^A$ at every child $E[x, y]$ of every $A$-unresolved unit $\downarrow E[x]$ such that $y \notin \text{Lim}(B(\downarrow E[x]))$.

The trivial pruning, denoted (just like the trivial resolution) by $\emptyset$, is the one that, for each $\downarrow$-unit, returns the pruner consisting of all finite bitstrings. Note that the limit set of such a pruner is the set of all infinite bitstrings. Hence it is clear that $F_1^{\emptyset} = F_1$. Thus, $F_1 = F_1^{\emptyset}$.

We say that two (finite or infinite) bitstrings $x$ and $y$ are comparable iff $x \leq y$ or $y \leq x$; otherwise they are incomparable.

A pillaring is a function $C$ that sends every unit $\downarrow E$ to a nonempty set $C(\downarrow E) = \{w_1, \ldots, w_r\}$, where $w_1, \ldots, w_r$ are pairwise incomparable finite bitstrings, called the $C$-pillars of $\downarrow E$. We additionally require that the following two conditions be satisfied:

- There is a number $r$ such that no $\downarrow$-unit has more than $r$ $C$-pillars; the smallest of such numbers $r$ is said to be the width of the pillaring $C$.
- There is a number $s$ such that no $C$-pillar of any $\downarrow$-unit is longer than $s$; the smallest of such numbers $s$ is said to be the height of the pillaring $C$.

When $A$ is a resolution, $B$ is a pruning and $C$ is a pillaring, the expression

$$F_1^{ABC}$$

denotes the unit tree that is the result of trimming $F_1^{AB}$ at every child $E[x, y]$ of every $A$-unresolved unit $\downarrow E[x]$ such that $y$ is not comparable with any of the $C$-pillars of $\downarrow E[x]$.

We say that a pillaring $C$ is concordant with a pruning $B$ iff, for every unit $\downarrow E$, every $C$-pillar of $\downarrow E$ is an element of the pruner $B(\downarrow E)$.

The trivial pillaring, denoted (just like the trivial resolution and the trivial pruning) by $\emptyset$, is the one that returns $\{\epsilon\}$ for each $\downarrow$-unit. Note that, for any resolution $A$ and pruning $B$, $F_1^{A\emptyset} = F_1^{AB}$. Thus, $F_1 = F_1^{\emptyset\emptyset}$.

A lightening of a pillaring $C$ is a pillaring $C'$ such that, for any unit $\downarrow E$, where $C(\downarrow E) = \{w_1, \ldots, w_r\}$, we have $C'(\downarrow E) = \{w'_1, \ldots, w'_r\}$, where, for each $i \in \{1, \ldots, r\}$, $w_i \leq w'_i$. Thus, $C'$ only differs from $C$ in that it makes some (maybe all, maybe none) of the pillars “taller”.

### 9.2 The $\uparrow$, $\downarrow$ and $\hat{\cdot}$ notations; unit incomparability; maturity

Let $a$ be a natural number, and $E$ a unit (resp. finite). By “numerically making the move $a$ in $E$” we shall mean making the numeric move $a$ in some politeral subunit (resp. politeral subfunit) of $E$. Of course, if $E$ is a politeral (f)unit, numerically making the move $a$ in $E$ simply means making the move $a$ in $E$. Otherwise, numerically making the move $a$ in $E$ means making a move $\beta$ in $E$ such that the string “$a$” is a suffix of $\beta^{\omega}$

---

5Strictly speaking, this is so only provided that the move we are talking about is legal. However, it should be remembered that, as we agreed in Section 5, our discourse is always $\Omega$, which, by (8), is a legal run.
Let \( a \) be a natural number, \( \triangleleft E \) a unit, and \( w \) a finite bitstring. By "numerically making the move \( a \) in branch \( w \uparrow \) of \( \triangleleft E \)" we shall mean making a move \( \beta \) in \( \triangleleft E \) such that the string "\( w \)" is a prefix of \( \beta \) and the string "\( a \)" is a suffix of \( \beta \). The same terminology, but without "\( \uparrow \)" extends from finite bitstrings \( w \) to infinite bitstrings \( x \). Namely, where \( x \) is an infinite bitstring, by "numerically making the move \( a \) in branch \( x \) of \( \triangleleft E \)" we mean numerically making the move \( a \) in branch \( w \uparrow \) of \( \triangleleft E \) for some finite prefix \( w \) of \( x \). Observe that numerically making the move \( a \) in branch \( w \uparrow \) of \( \triangleleft E \) signifies numerically making the move \( a \) in every branch \( x \) of \( \triangleleft E \) with \( w \preceq x \). Also note that, where \( \triangleleft [E[y]] \) is the extended form of \( \triangleleft E \), numerically making the move \( a \) in branch \( x \) of \( \triangleleft E \) means nothing but numerically making the move \( a \) — in the sense of the preceding paragraph — in the child \( E[y, x] \) of \( \triangleleft E \).

For a natural number \( m \), we shall write

\[ \Omega_m \]

for the initial segment of \( \Omega \) (the run fixed in Section 5) that consists of the moves made at times (clock cycles) not exceeding \( m \). Next, where \( E \) is a unit, by

\[ E \downarrow m \]

we denote the regular funital restriction of \( E \) of height \( h \), where \( h \) be the greatest of the heights of the \( \Omega_m \)-active funits (see Section 4). An exception here is the case when the modal depth of \( E \) is 0 (and hence all funital restrictions of \( E \) coincide with \( E \) and are of height 0); in this case, \( E \downarrow m \) simply means \( E \).

We say that two units \( E \) and \( G \) are incomparable iff \( E \) is neither a subunit nor a superunit of \( G \). Where \( m \) is a natural number, we say that \( E \) and \( G \) are \( \downarrow m \)-incomparable iff \( E \downarrow m \) is neither a subunit nor a superunit of \( G \downarrow m \). Note that this is the same as to say that the address of \( E \downarrow m \) is neither a prefix nor an extension of the address of \( G \downarrow m \).

**Lemma 9.2** Below \( m \) and \( m' \) range over natural numbers.

1. Whenever two units are \( \downarrow m \)-incomparable, they are also \( \downarrow m' \)-incomparable for every \( m' \geq m \).
2. For any incomparable units \( E \) and \( G \) there is an \( m \) such that \( E \) and \( G \) are \( \downarrow m \)-incomparable.

**Proof.** Clause 1 is a straightforward observation. For clause 2, consider any incomparable units \( E, G \). Let \( H \) be the smallest common superunit of \( E \) and \( G \).

First, assume \( H \) has the form \( H_1 \wedge H_2 \) or \( H_1 \lor H_2 \). We may assume that \( E \) is a subunit of \( H_1 \). Then \( G \) is a subunit of \( H_2 \), for otherwise the smallest common superunit of \( E \) and \( G \) would be \( H_1 \) — or some proper subunit of the latter — rather than \( H \). Let \( a \) be the address of \( H \downarrow 0 \). Note that then \( \alpha a \) is a prefix of the address of \( E \downarrow 0 \), and \( \alpha 1 \) is a prefix of the address of \( G \downarrow 0 \). So, the address of \( E \downarrow 0 \) is neither a prefix nor an extension of the address of \( G \downarrow 0 \). In other words, \( E \) and \( G \) are \( \downarrow 0 \)-incomparable.

Now assume \( H \) has the form \( \triangleleft H_1 \) or \( \triangledown H_1 \). Note that then, in its extended form, \( E \) looks like \( E[x, y_1, z_1] \) and \( G \) looks like \( E[x, y_2, z_2] \), where \( x \) is a sequence of as many infinite bitstrings as the modal depth of \( H \), and where \( y_1 \neq y_2 \). Let \( h \) be the length of the shortest bitstring that is not a common prefix of \( y_1 \) and \( y_2 \). Since \( E \) keeps making moves in prompts of increasing heights, by a certain time \( m \), it will have made a move in a (regular) funit of height \( \geq h \). This clearly makes \( E \) and \( G \) \( \downarrow m \)-incomparable.

Let \( m \) be a natural number. We say that a domination chain

\[ L_1, M_1, X_1, \ldots, L_n, M_n, X_n \]

is mature at time \( m \) iff, whenever \( i, j \in \{1, \ldots, n\}, H_i \) (resp. \( H_j \)) is a superunit of \( M_i \) (resp. \( M_j \)) and \( H_i \) is incomparable with \( H_j \), we have that \( H_i \) is also \( \downarrow m \)-incomparable with \( H_j \).

**Lemma 9.3** For every domination chain \( \bar{D} \) there is an integer \( m \) such that, for any \( m' \geq m \), \( \bar{D} \) is mature at time \( m' \).
Proof. Immediately from Lemma 9.2 and the obvious fact that any unit has only finitely many superunits. ■

For a unit $E$ and natural numbers $a$ and $m$, we write

$$\sqsubseteq a\bar{e}_m E \quad (\text{resp. } \sqsupseteq a\bar{e}_m E)$$

to mean that $a$ has been numerically made in $E$ by $E$ (resp. $E$’s adversary) at time $m$. When we omit the subscript $m$ and simply write $\sqsubseteq a\bar{e} E$, we mean “$\sqsubseteq a\bar{e}_m E$ for some $m$”. Similarly for $\sqsupseteq a\bar{e} E$. As expected, $\not\in$ means “not $\bar{e}$”.

Lemma 9.4 Assume $F$ is a unit tree, $H, \hat{\diamond} E, G \in F$, $m_0$ is a natural number,

$$L_1, M_1, X_1, \ldots, L_n, M_n, X_n$$

is a $\hat{\diamond} E$-over-$G$ domination chain in $F$ mature at time $m_0$, and $b_1, \ldots, b_n$ are natural numbers such that, for each $k \in \{1, \ldots, n\}$, $\sqsubseteq b_k\bar{e}_{m_k} M_k$ (and hence also $\sqsubseteq b_k\bar{e}_{m_k} X_k$) for some $m_k \geq m_0$. Then there is at most one $k \in \{1, \ldots, n\}$ such that $\hat{H}$ is an osubformula of $X_k$ and $\sqsubseteq b_k\bar{e} H$.

Proof. Assume the conditions of the lemma. For a contradiction, additionally assume that $1 \leq k_1 < k_2 \leq n$, $\hat{H}$ is an osubformula of both $X_{k_1}$ and $X_{k_2}$, and both $\sqsubseteq b_{k_1}\bar{e} H$ and $\sqsubseteq b_{k_2}\bar{e} H$.

We know that $\hat{E}$ made the numeric move $a_{k_1}$ in $M_{k_1}$ at time $m_{k_1}$. Analyzing the work of $E$, this can easily be seen to imply that such a move was, in fact, made in the finital restriction $M_{k_1} \downarrow m_{k_1}$ of $M_{k_1}$. This, in turn, implies that $M_{k_1} \downarrow m_{k_1}$ is a subunit of $H' \downarrow m_{k_1}$ (otherwise we would not have $\sqsubseteq a_{k_1} H$).

The latter further implies that $M_{k_1} \downarrow m_{k_1}$ is a subunit of $H \downarrow m_0$ (because $m_0 \leq k_1$). It is therefore obvious that there is a unital extension $H''$ of $H \downarrow m_0$ such that $M_{k_2}$ is a subunit of $H''$. Using similar reasoning, we also find that there is a unital extension $H''$ of $H \downarrow m_0$ such that $M_{k_2}$ is a subunit of $H''$. Also, of course, $H' = \hat{H}$, so that $H'$ is an osubformula of $X_{k_1}$.

Since both $H'$ and $H''$ are unital extensions of $H \downarrow m_0$, we have $H' \downarrow m_0 = H'' \downarrow m_0 = H \downarrow m_0$. This means that $H'$ and $H''$ are not $\downarrow m_0$-incomparable. Hence, due to the maturity of (6) at time $m_0$, $H'$ and $H''$ are simply the same. Thus, $H'$ is a superunit of both $M_{k_1}$ and $M_{k_2}$.

Since both $H'$ and $X_{k_1}$ are superunits of $M_{k_1}$, $H'$ and $X_{k_1}$ have to be comparable. The latter, in view of the fact that $H'$ is an osubformula of $X_{k_1}$, obviously means that $H'$ is a subunit of $X_{k_1}$.

But then, since $H'$ is a superunit of both $M_{k_1}$ and $M_{k_2}$, either $H'$ or one of its proper subunits is the smallest common superunit $Y$ of $M_{k_1}$ and $M_{k_2}$, where no proper $\hat{\diamond}$-superunit of $M_{k_1}$ is a subunit of $Y$.

So, $M_{k_1}$ drives $M_{k_2}$ through $Y$. In turn, since (6) is a $\hat{\diamond} E$-over-$G$ domination chain, $M_{k_2}$ drives $L_{k_2 + 1}$ (if $k_2 < n$) or $G$ (if $k_2 = n$). Thus, by clause 1 of Lemma 9.3, $M_{k_1}$ drives $L_{k_2 + 1}$ (if $k_2 < n$) or $G$ (if $k_2 = n$). This, however, is impossible according to the definition of domination chain. ■

9.3 The operation ONE

We say that a tuple $(A, B, C, \hat{T}, \hat{\diamond} E, G)$ is **ONE-appropriate** iff $A$ is a resolution, $B$ is a pruning, $C$ is a pillaring concordant with $B$, $\hat{T}$ is a domination chain-type, $\hat{\diamond} E, G \in F_1^{ABC}$, and $C(\hat{\diamond} E)$ is a singleton.

For the rest of this section, we fix an arbitrary ONE-appropriate tuple $(A, B, C, \hat{T}, \hat{\diamond} E, G)$. The operation **ONE** that we are going to describe takes such a tuple and returns a pillaring, denoted by

\[ \text{ONE}(A, B, C, \hat{T}, \hat{\diamond} E, G). \]

9.3.1 The construction of ONE

Let us rename the pillaring $C$ into $C^{-1}$ (yes, the superscript is “minus 1”). We do our construction — henceforth referred to as the “construction of ONE” — of the pillaring \[ \text{ONE}(A, B, C, \hat{T}, \hat{\diamond} E, G) \] in consecutive steps, starting from step #0. Each step #i returns a pillaring $C^i$ such that $C^i$ is a
The event could only have occurred after $E$'s numeric moves.

Chaining of (iii) unless (ii) there is a $\Omega$-pillar.

Once, $\#(i - 1)$ step.

**Step #i:** Let $v_i$ be the (unique) $C^{i-1}$-pillar of $\hat{\mathcal{E}}_E$, and let $S = \mathcal{B}(\hat{\mathcal{E}}_E)$. Let $D^i$ be the pillaring such that $\mathcal{D}^i(\hat{\mathcal{E}}_E) = \{ [v_i] \cdot 0 \}$ and, on all other $\hat{\mathcal{E}}$-units, $D^i$ agrees with $C^{i-1}$.

If there is no $\hat{\mathcal{E}}$-over-$G$ domination chain of type $\hat{T}$ in $\mathcal{F}_1^{ABD}$, then we declare the construction to be **complete**, and let $C^i = D^i = \text{ONE}(\mathcal{A}, \mathcal{B}, \mathcal{C}, \hat{T}, \hat{\mathcal{E}}_E, G)$.

Otherwise, we declare the construction to be **incomplete**, and pick — according to some fixed choice function — a $\hat{\mathcal{E}}$-over-$G$ domination chain

$$L^i_1, M^i_1, X^i_1, \ldots, L^i_n, M^i_n, X^i_n \quad (7)$$

(fix it!) of type $\hat{T}$ in $\mathcal{F}_1^{ABD}$.

Let $m^i_0$ be the smallest natural number satisfying the following conditions:

(i) the chain $\mathcal{E}$ is mature at time $m^i_0$.

(ii) there is a $\Omega_{m^i_0}$-active unit whose height exceeds the height of the pillaring $D^i$.

(iii) unless $i = 0$, we have $m^i_0 > m^{i-1}_{n-1}$, where $m^{i-1}_n$ is the value obtained at step $\#(i - 1)$ in the same way as we are going to obtain the value $m^i_n$ at the present step shortly.

For each $k \in \{1, \ldots, n\}$, we now define the natural numbers $l^i_k, a^i_k, t^i_k, m^i_k, b^i_k$ as follows:

- $l^i_k$ is the smallest number with $l^i_k > m^{i-1}_k$ such that $\mathcal{E}$ moved in $L^i_k$ at time $l^i_k$, and $a^i_k$ is the numeric move made by $\mathcal{E}$ in $L^i_k$ at that time (that is, $\perp a^i_k \hat{\mathcal{E}}_{l^i_k} L^i_k$);

- $t^i_k$ is the time with $t^i_k > l^i_k$ at which the adversary of $\mathcal{E}$ made the same numeric move $a^i_k$ in $M^i_k$ (that is, $\hat{T} a^i_k \hat{\mathcal{E}}_{t^i_k} M^i_k$);

- $m^i_k$ is the smallest number with $m^i_k > t^i_k$ such that $\mathcal{E}$ moved in $M^i_k$ at time $m^i_k$, and $b^i_k$ is the numeric move made by $\mathcal{E}$ in $M^i_k$ at that time (that is, $\perp b^i_k \hat{\mathcal{E}}_{m^i_k} M^i_k$).

We now let $C^i$ be the (unique) pillaring satisfying the following conditions:

1. $C^i(\hat{\mathcal{E}}_E) = \{ [v_i] \cdot 0 \}$.

2. Consider any unit $\hat{\mathcal{E}}_H$ other than $\hat{\mathcal{E}}_E$. Let $w_1, \ldots, w_p$ be the $C^{i-1}$-pillars of $\hat{\mathcal{E}}_H$. Then the $C^i$-pillars of $\hat{\mathcal{E}}_H$ are $w'_1, \ldots, w'_p$, where, for each $j \in \{1, \ldots, p\}$, $w'_j$ is defined as follows:

   (a) Assume, for one of $k \in \{1, \ldots, n\}$, $\perp b^i_k \hat{\mathcal{E}}_{m^i_k} \hat{\mathcal{E}}_H$ and $\hat{\mathcal{E}}_H$ is an os formula of $\hat{\mathcal{E}}_k$ (in view of Lemma 9.4 such a $k$ is unique). Further assume that the move $b^i_k$ was numerically made in branch $u^\uparrow$ of $\hat{\mathcal{E}}_H$. Then $w'_j = [u] \cdot 0$.

   (b) Otherwise $w'_j = w_j$.

This completes our description of step $\#i$.

\textsuperscript{6}Lemma 9.3 guarantees that $m^i_0$ can always be chosen so as to satisfy this condition.

\textsuperscript{7}Since $\mathcal{E}$ makes numeric moves in funits of ever increasing heights, $m^i_0$ can always be chosen so as to satisfy this condition. Of course, our earlier assumption that $\mathcal{F}_0$ is not $\hat{\mathcal{E}}$-free (see the paragraph following Lemma 9.1) is relevant here.

\textsuperscript{8}$\mathcal{E}$'s adversary indeed must have made the move $a^i_k$ in $M^i_k$, for otherwise $L^i_k$ and $M^i_k$ would not be opposite; however, this event could only have occurred after $\mathcal{E}$ made the move $a^i_k$ because, as we remember from (2), $\mathcal{E}$ always chooses fresh numbers for its numeric moves.
Lemma 9.5 Where all parameters are as in the description of Step \#i, the pillaring $C^i$ is a heightening of the pillaring $C^{i-1}$ and, as long as the former is concordant with $B$, so is the latter.

Consequently (by induction on i), $C^i$ is a heightening of $C$ and is (remains) concordant with $B$.

Proof. Rather obvious in view of our choice of $C^i$ and the condition (ii) that $m^i_j$ is required to satisfy. ■

Of course, the value of ONE remains undefined on $(A, B, C, \tilde{T}, \check{E}, G)$ if the construction of ONE never terminates. However, the following lemma, proven in Section 9.3.2, rules out this possibility, so that ONE is defined on all ONE-appropriate tuples:

Lemma 9.6 There is a number i such that the construction of ONE is complete at step \#i.

9.3.2 Termination of the construction of ONE

This section is exclusively devoted to a proof of Lemma 9.6. A fixed ONE-appropriate tuple we are dealing with is the same $(A, B, C, \tilde{T}, \check{E}, G)$ as before. So are the parameters $v_i, S, L^i_k, M^i_k, X^i_k, a^i_j, b^i_j, t^i_j, m^i_j$ from the construction of ONE. Remember that the length of $\tilde{T}$ is $3n$, and that $S = B(\check{E})$.

We additionally fix a sufficiently large integer $r$ such that

the width of $C$ (and hence, by Lemma 9.3 of each $C^i$) does not exceed $r$; \hspace{1cm} (8)

the modal depth of no osubformula of $F_0$ exceeds $r$. \hspace{1cm} (9)

For a contradiction, deny the assertion of Lemma 9.6. In particular, assume that none of the steps \#0 through \#$r^{3n}$ of the construction of ONE is final.

For a finite set $K$, we write $|K|$ to denote the cardinality of $K$.

Lemma 9.7 Assume $k \in \{1, \ldots, n\}$, $S$ is a nonempty subset of $\{0, \ldots, r^{3n}\}$, $i_0$ is the greatest element of $S$, and the following condition is satisfied:

For any $i, j \in S$ with $j < i$, $\bot a^i_j \notin L^i_k$. \hspace{1cm} (10)

Further, let

$\mathcal{S}_0 = \{j \mid j \in S, \bot b^i_j \notin X^i_k\}$.

Then $|\mathcal{S}_0| \leq r^r$.

Proof. Let $k, S, i_0, \mathcal{S}_0$ be as in the conditions of the lemma. In addition, we rename $X^i_k$ into $Y_0$ and assume that the extended form of the latter is $\check{Y}_0[x^0]$. Thus,

$X^i_k = Y_0 = \check{Y}_0[x^0]$.

For a contradiction, assume

$|\mathcal{S}_0| > r^r$. \hspace{1cm} (11)

Let $d$ be the number of the $\check{E}$-superunits of $M^i_k$ that happen to be subunits of $Y_0$. Namely, let $\check{Y}_1, \ldots, \check{Y}_d$ be all such superunits, with $\check{Y}_1$ being a proper superunit of $\check{Y}_2$, $\check{Y}_2$ a proper superunit of $\check{Y}_3$, and so on. At the same time, since $M^i_k$ drives $L^i_{k+1}$ (if $k < n$) or $G$ (if $k = n$) through $Y_0$, $M^i_k$ has no $\check{Y}$-superunit that happens to be a subunit of $Y_0$. This means that, for some infinite bitstrings $x^0_1, \ldots, x^0_d$ (fix them), we have

$\check{Y}_1 = \check{Y}_1[x^0_1],$
$\check{Y}_2 = \check{Y}_2[x^0_1, x^0_2],$
$\check{Y}_3 = \check{Y}_3[x^0_1, x^0_2, x^0_3],$
$\ldots$
$\check{Y}_d = \check{Y}_d[x^0_1, x^0_2, \ldots, x^0_{d-1}],$
$M^i_k = M^i_k[x^0_1, x^0_2, \ldots, x^0_d].$
Similarly, for any $j \in G_0$, let $x_0^j, x_1^j, \ldots, x_d^j$ be such that $X_k^j = \bar{Y}_0[x_0^j]$, the latter is a superunit of $\triangleleft \bar{Y}_1[x_0^j]$, the latter is a proper superunit of $\triangleleft \bar{Y}_2[x_0^j, x_1^j]$, the latter is a proper superunit of $\triangleleft \bar{Y}_3[x_0^j, x_1^j, x_2^j]$, $\ldots, \triangleleft \bar{Y}_{d-1}[x_0^j, x_1^j, \ldots, x_{d-2}^j]$ is a proper superunit of $\triangleleft \bar{Y}_d[x_0^j, x_1^j, \ldots, x_{d-1}^j]$, and the latter is a superunit of $M_k^j = M_k^j[x_0^j, x_1^j, \ldots, x_d^j]$.

According to our definition of $G_0$, we have:

$$\text{for any } j \in G_0, \quad \exists b_k^j \subseteq \bar{Y}_0[x_0^j].$$

For each $j \in G_0$, let $w_1^j$ be the finite bitstring such that the corresponding move $b_k^j$ was numerically made (at time $m_k^j$) by $E$ in branch $w_1^j \uparrow$ of $\triangleleft \bar{Y}_1[x_0^j]$. Our choice of the pillaring $C'$ in (step $\# j$ of) the construction of $\text{ONE}$ guarantees that each $w_1^j$ is a prefix of one of the $C'$-pillars of $\triangleleft \bar{Y}_1[x_0^j]$ And since, by Lemma 9.3 every subsequent pillaring (namely, the pillaring $\mathbf{C}$) is a lightening of the previous ones (namely, of the pillaring $\mathbf{C}'$), we find that each $w_1^j$ is a prefix of one of the $C'$-pillars of $\triangleleft \bar{Y}_1[x_0^j]$. Next, by (3), we know that the number of such pillars does not exceed $r$. Thus, by the pigeonhole principle, there is a $C_k^0$-pillar $p_1$ of $\triangleleft \bar{Y}_1[x_0^j]$ and a subset $G_1$ of $G_0$ with $|G_1| \geq \frac{|G_0|}{r}$ such that, for every $j \in G_1$, $w_1^j \preceq p_1$. But, by (11), $|G_0| > r^m$. So, $|G_1| > r^{m-1}$. In view of (3), we also have $d \leq r$. Consequently,

$$|G_1| > r^{d-1}.$$

Let $i_1$ be the greatest element of $G_1$. Consider an arbitrary $j \in G_1$. Since $b_k^j \subseteq \bar{Y}_0[x_0^j]$ and $E$ makes every numeric move only once, the move $b_k^j$ was numerically made by $E$ at time $m_k^j$ in both $\bar{Y}_0[x_0^j]$ and $\bar{Y}_0[x_0^j]$. As observed in a similar situation in the proof of Lemma 9.3 the move $b_k^j$ was, in fact, numerically made by $E$ in the finitist restrictions $\bar{Y}_0[x_0^j] \downarrow m_k^j$ and $\bar{Y}_0[x_0^j] \downarrow m_k^j$ of $\bar{Y}_0[x_0^j]$ and $\bar{Y}_0[x_0^j]$, respectively. Clearly this implies that $\bar{Y}_0[x_0^j] \downarrow m_k^j = \bar{Y}_0[x_0^j] \downarrow m_k^j$. Applying the same reason to $i_1$ in the role of $j$, we also find $\bar{Y}_0[x_0^j] \downarrow m_k^j = \bar{Y}_0[x_0^j] \downarrow m_k^j$ and hence, as $j \leq i_1$, $\bar{Y}_0[x_0^j] \downarrow m_k^j = \bar{Y}_0[x_0^j] \downarrow m_k^j$. Thus, $\bar{Y}_0[x_0^j] \downarrow m_k^j = \bar{Y}_0[x_0^j] \downarrow m_k^j$. Since $j < i_1$, we also have $w_1^j \preceq w_1^j \preceq x_1^j$ (this can be seen from the fact that the heights of finits in which $E$ makes moves keep increasing). In view of this observation, the equation $\bar{Y}_0[x_0^j] \downarrow m_k^j = \bar{Y}_0[x_0^j] \downarrow m_k^j$ obviously implies $\bar{Y}_1[x_0^j, x_1^j] \downarrow m_k^j = \bar{Y}_1[x_0^j, x_1^j] \downarrow m_k^j$. But the move $b_k^j$ was numerically made by $E$ in $\bar{Y}_1[x_0^j, x_1^j]$ at time $m_k^j$. Hence it was also numerically made (at the same time) in $\bar{Y}_1[x_0^j, x_1^j]$. To summarize, we have:

$$\text{for any } j \in G_1, \quad \exists b_k^j \subseteq \bar{Y}_1[x_0^j, x_1^i].$$

For each $j \in G_1$, let $w_1^j$ be the finite bitstring such that the corresponding move $b_k^j$ was numerically made by $E$ in branch $w_1^j \uparrow$ of $\triangleleft \bar{Y}_2[x_0^j, x_1^j]$. As in the previous case, we find that each $w_2^j$ has to be a prefix of one of the $C'$-pillars of $\triangleleft \bar{Y}_2[x_0^j, x_1^j]$. And, since the number of such pillars does not exceed $r$ as in the previous case, there is a $C'$-pillar $p_2$ of $\triangleleft \bar{Y}_2[x_0^j, x_1^j]$ and a subset $G_2$ of $G_1$ with

$$|G_2| > r^{d-2}$$

such that, for every $j \in G_2$, $w_2^j \preceq p_2$. Let $i_2$ be the greatest element of $G_2$. As in the previous case, we find that

$$\text{for any } j \in G_2, \quad \exists b_k^j \subseteq \bar{Y}_2[x_0^j, x_1^i].$$

Continuing this way, we eventually find that there is a subset $G_d$ of $G_0$ with

$$|G_d| > r^{d-d} = 1$$

such that

$$\text{for any } j \in G_d, \quad \exists b_k^j \subseteq \bar{Y}_d[x_0^j, x_1^i, \ldots, x_d^i].$$

Remembering that $M_k^{\mathbf{M}} = M_k[x_0^j, x_1^i, \ldots, x_d^i]$, and that the move $b_k^j$ was made by $E$ in $\bar{M}_k^j$ (rather than in any other politoral subunits of $\bar{Y}_d[x_0^j, x_1^i, \ldots, x_d^i]$) with a little thought one can see that (13) implies the following:

$$\text{for any } j \in G_d, \quad \exists b_k^j \subseteq \bar{M}_k^j.$$
Let us rename \( i_d \) into \( i \). Further, let \( j \) be an element of \( \mathcal{S}_d \) different from \( i \), meaning that \( j < i \) (the existence of such a \( j \) is guaranteed by (12)). Obviously (14) implies that \( \exists a^1_j \in M^*_j \), because \( \mathcal{E} \) made its move \( b^1_j \) only in units in which its adversary already had made the move \( a^1_j \). Hence, as \( M^*_j \) and \( L^*_j \) are opposite, we have \( \perp a^1_j \in L^*_j \). This, however, contradicts (10). ■

By induction, we now establish the existence of \( n + 1 \) sets

\[
S_n \subseteq S_{n-1} \subseteq \ldots \subseteq S_1 \subseteq S_0 \subseteq \{0, \ldots, r^{r^n}\}
\]
such that, for each \( k \in \{0, \ldots, n\} \), the following three conditions are satisfied:

\[
|S_k| > r^{r(n-k)}.
\]  
(15)

If \( k > 0 \), then, for any \( i, j \in S_k \) with \( j < i \), \( \perp b^1_{k+1} \notin X^i_{k+1} \).  
(16)

If \( k < n \), then, for any \( i, j \in S_k \) with \( j < i \), \( \perp a^1_{k+2} \notin \hat{L}^i_{k+2} \).  
(17)

We define \( S_0 \) by

\[
S_0 = \{0, \ldots, r^{r^n}\}.
\]

The cardinality of this set is \( r^{r^n} + 1 > r^{r(n-0)} \) so condition (15) is satisfied for \( k = 0 \). Condition (16) for \( k = 0 \) is satisfied vacuously. As for condition (17), consider any \( i, j \in S_0 \) such that \( j < i \). With some analysis of the construction of one we can see that \( \mathcal{E} \) numerically made the move \( a^1_j \) only in branches of \( \hat{E} \) that extend \( \mathcal{X}_j \) so that it numerically made the move \( a^1_j \) only in branches of \( \hat{E} \) that extend \( \mathcal{X}_j \). To summarize, \( \mathcal{E} \) has never numerically made both moves \( a^1_j \) and \( a^1_j \) in the same child of \( \hat{E} \), and hence in the same polar unit \( L^*_i \) for whatever \( e \in S_0 \). Taking into account that \( \mathcal{E} \) however did make the move \( a^1_j \) in \( L^*_i \), we now find that it could not have made the move \( a^1_j \) in \( L^*_i \). That is, \( a^1_j \notin L^*_i \), so that condition (17) is also satisfied for \( k = 0 \).

Now consider any \( k \) with \( 0 < k < n \) and assume that we have already established the existence of a set \( S_k \) satisfying conditions (15), (16) and (17). We want to see that there is a set \( S_{k+1} \) satisfying the following three conditions (the same conditions as (15), (16) and (17) but with \( k + 1 \) instead of \( k \)):

\[
|S_{k+1}| > r^{r(n-(k+1))}.
\]  
(18)

For any \( i, j \in S_{k+1} \) with \( j < i \), \( \perp b^1_{k+1} \notin X^i_{k+1} \).  
(19)

If \( k + 1 < n \), then, for any \( i, j \in S_{k+1} \) with \( j < i \), \( \perp a^1_{k+2} \notin \hat{L}^i_{k+2} \).  
(20)

Let \( e_1 \) be the greatest element of \( S_k \), and let

\[
\Omega_1 = \{ j \mid j \in S_k, \perp b^1_{k+1} \notin X^e_{k+1} \}.
\]

Next, let \( e_2 \) be the greatest element of \( S_k - \Omega_1 \), and let

\[
\Omega_2 = \{ j \mid j \in S_k - \Omega_1, \perp b^1_{k+1} \notin X^e_{k+1} \}.
\]

Next, let \( e_3 \) be the greatest element of \( S_k - (\Omega_1 \cup \Omega_2) \), and let

\[
\Omega_3 = \{ j \mid j \in S_k - (\Omega_1 \cup \Omega_2), \perp b^1_{k+1} \notin X^e_{k+1} \}.
\]

We continue in the above style and define pairs \((e_4, \Omega_4)\), \((e_5, \Omega_5)\), \ldots until we hit a pair \((e_q, \Omega_q)\) such that selecting the subsequent pair is no longer possible — namely, we have

\[
S_k - (\Omega_1 \cup \ldots \cup \Omega_q) = \emptyset, \text{ i.e. } S_k = \Omega_1 \cup \ldots \cup \Omega_q.
\]  
(21)

Now, we define \( S_{k+1} \) by

\[
S_{k+1} = \{ e_1, \ldots, e_q \}.
\]
To verify condition (18), first note that, since \( k < n \) in our present case, (17) can be rewritten as

For any \( i, j \in S_k \) with \( j < i \), \( \perp a_{k+1} L_{k+1} \).

The above, of course, implies the following for any \( f \in \{1,\ldots,q\} \):

For any \( i, j \in S_k - (\Omega_1 \cup \ldots \cup \Omega_f - 1) \) with \( j < i \), \( \perp a_{k+1} L_{k+1} \).

(here, if \( f = 1 \), \( S_k - (\Omega_1 \cup \ldots \cup \Omega_f - 1) \) is to be understood as simply \( S_k \)). Now note that (22) is nothing but the condition (10) of Lemma 9.7, with \( S_k - (\Omega_1 \cup \ldots \cup \Omega_f - 1) \) in the role of \( S \) and \( k + 1 \) in the role of \( k \). Hence, by Lemma 9.7, with \( e_f \) in the role of \( i_0 \) and \( \Omega_f \) in the role of \( \mathcal{G}_0 \), we find that

\[ |\Omega_f| \leq r^n \quad \text{(for any } f \in \{1,\ldots,q\} \).

Thus, by (21) and (23), \( S_k \) is the union of \( q \) sets (the sets \( \Omega_1, \ldots, \Omega_q \)), with the cardinality of none of those sets exceeding \( r^n \). Therefore

\[ q \geq \frac{|S_k|}{r^n}, \]

i.e.,

\[ |S_{k+1}| \geq \frac{|S_k|}{r^n}. \]

At the same time, from (15), we know that \( |S_k| > r^n(n-k) \). Thus,

\[ |S_{k+1}| > \frac{r^n(n-k)}{r^n} = r^{(n-k)-r} = r^{r(n-k)-1} = r^{r(n-(k+1))}. \]

This proves the truth of condition (18).

Now, consider any \( i, j \in S_{k+1} \) with \( j < i \). From our construction of \( S_{k+1} \), it is immediate that \( \perp b_{k+1} X_{k+1}^j \), which takes care of condition (19). To see that condition (20) is also satisfied, assume, for a contradiction, that \( k+1 < n \) and \( \perp a_{k+2} L_{k+2} \). With some thought, this can be seen to imply that \( X_{k+1}^j \perp L_{k+2} \perp X_{k+1}^j \). Since \( m_{k+1}^j < m_{k+2}^j \), we then also have \( X_{k+1}^j \perp m_{k+1}^j = X_{k+1}^j \perp m_{k+1}^j \). So, the move \( b_{k+1} \) numerically made by \( \mathcal{E} \) at time \( m_{k+1}^j \) in \( (M_{k+1}^j \perp X_{k+1}^j \perp \mathcal{E}) \) was also simultaneously numerically made in \( X_{k+1}^j \). That is, \( \perp b_{k+1} X_{k+1}^j \). But, from the already verified condition (19), we know that this is not the case.

This completes our construction of the sets \( S_0, \ldots, S_n \) and our proof of the fact that each such set \( S_k \) satisfies conditions (15), (16) and (17).

Taking \( k = n \) in (15), we find that the set \( S_n \) contains at least two distinct elements \( i \) and \( j \). Let us say \( j < i \). By condition (16), \( \perp b_{k+1} X_{k+1}^j \). On the other hand, of course, \( \perp b_{k+1} X_{k+1}^j \). This implies that the units \( X_{k+1}^j \) and \( X_{k+1}^j \) are incomparable. But note that both units are superunits of \( G \). We have thus reached a contradiction, because the same unit obviously cannot have two incomparable superunits. Lemma 9.6 is now proven.

9.3.3 The One-lemma

**Lemma 9.8** Assume \((A, B, C, \bar{T}, \overline{\bullet} E, G)\) is a One-appropriate tuple, and

\[ C' = \text{ONE}(A, B, C, \bar{T}, \overline{\bullet} E, G). \]

Then:

1. \( C' \) is a heightening of \( C \), and it is concordant with \( B \).
2. There is no \( \overline{\bullet} E \)-over-\( G \) domination chain of type \( \bar{T} \) in \( F_{1}^{ABC'} \).

**Proof.** Assume the conditions of the present lemma. Clause 1 immediately follows from Lemma 9.5. For clause 2, let \( i \) be the number whose existence is claimed in Lemma 9.6. Then, where \( C_i \) and \( D_i \) are as in (step \#i of) the construction of One, we have \( C' = C_i = D_i \). But, looking back at that construction, we see that the reason why the latter was complete at step \#i is that there was no \( \overline{\bullet} E \)-over-\( G \) domination chain of type \( \bar{T} \) in \( F_{1}^{ABD} = F_{1}^{ABC'} \).
9.4 The operation $\text{ONE}^+$

Remember that we have defined a domination chaintype as any sequence of $3n$ oformulas where $n \geq 1$. Weakening the condition $n \geq 1$ to $n \geq 0$ yields what we refer to as a generalized domination chaintype. That is, the set of generalized domination chaintypes is that of domination chaintypes plus the empty sequence of oformulas.

We define a $\text{ONE}^+$-appropriate tuple $(A, B, C, \vec{T}, \d E, G)$ exactly as we defined a $\text{ONE}$-appropriate tuple, with the only difference that $\vec{T}$ can now be empty. That is, now $\vec{T}$ is required to be a generalized domination chaintype rather than a domination chaintype.

When $(A, B, C, \vec{T}, \d E, G)$ is a $\text{ONE}^+$-appropriate tuple, we define the pillaring

$$C' = \text{ONE}^+(A, B, C, \vec{T}, \d E, G)$$

as follows:

- If $\vec{T}$ is nonempty, then $C' = \text{ONE}(A, B, C, \vec{T}, \d E, G)$.
- If $\vec{T}$ is empty but $G$ is not a proper subunit of $\d E$, then $C' = C$.
- Suppose now $\vec{T}$ is empty and $G$ is a proper subunit of $\d E$. Let $\d E[\vec{y}]$ be the extended form of $\d E$, and $\d E[\vec{y}, x]$ be the (unique) child of $\d E$ which is a superunit of $G$. Also, let $v$ be the (unique) $C$-pillar of $\d E$, and $S = B(\d E)$. Note that exactly one of the two strings $[v]\cdot 0$ or $[v]\cdot 1$ is a prefix of $x$. If $[v]\cdot 0 \leq x$ (resp. $[v]\cdot 1 \leq x$), we define $C'$ as the pillaring that sends $\d E$ to $\{(v)\} \mathrm{ (resp. } \{(v)\} \}$ and agrees with $C$ on all other $\d$-units.

**Lemma 9.9** Assume $(A, B, C, \vec{T}, \d E, G)$ is a $\text{ONE}^+$-appropriate tuple, and

$$C' = \text{ONE}^+(A, B, C, \vec{T}, \d E, G).$$

Then:

1. $C'$ is a hightening of $C$, and it is concordant with $B$.
2. If $\vec{T}$ is nonempty, then there is no $\d E$-over-$G$ domination chain of type $\vec{T}$ in $\mathbb{F}_1^{ABC'}$.
3. If $\vec{T}$ is empty and $G$ is a proper subunit of $\d E$, then $G \notin \mathbb{F}_1^{ABC'}$.

**Proof.** Clauses 1 and 2 are immediate from the corresponding two clauses of Lemma 9.8 and the way $C'$ is defined. Clause 3 can be verified through straightforward analysis. \[\square\]

9.5 The operation $\text{Two}$

By a Two-appropriate tuple we mean $(A, B, C, \vec{T}, \d E, G, \mathfrak{T})$, where $(A, B, C, \vec{T}, \d E, G)$ is a $\text{ONE}^+$-appropriate tuple and $\mathfrak{T}$ is a set of units such that, for any unit $\d H \in \mathfrak{T}$, $C(\d H)$ is a singleton.

Let $(A, B, C, \vec{T}, \d E, G, \mathfrak{T})$ be a Two-appropriate tuple, and let $C' = \text{ONE}^+(A, B, C, \vec{T}, \d E, G)$. We define

$$\text{Two}(A, B, C, \vec{T}, \d E, G, \mathfrak{T})$$

as the pillaring $C''$ such that, for any unit $\d H$:

- if $\d H \in \mathfrak{T}$, then $C''(\d H) = C'(\d H)$;
- otherwise, where $C'(\d H) = \{w_1, w_2, \ldots, w_r\}$, $B(\d H) = S$ and $[w]$ means $[w]^S$, we have $C''(\d H) = \{[w_1]0, [w_1]1, [w_2]0, [w_2]1, \ldots, [w_r]0, [w_r]1\}$.

**Lemma 9.10** Assume $(A, B, C, \vec{T}, \d E, G, \mathfrak{T})$ is a Two-appropriate tuple, and

$$C'' = \text{Two}(A, B, C, \vec{T}, \d E, G, \mathfrak{T}).$$
Lemma 9.9. Clauses 4 and 5 easily follow from clause 1 of Lemma 9.9 and the way visible to defined as follows.

Three

9.6 The operation Three

By a Three-appropriate tuple we mean a triple \((A, B, \Sigma)\), where \(A\) is a resolution, \(B\) is a pruning, and \(\Sigma\) is a countable set of units closed under visibility in \(A\) (for any units \(G, E\), if \(G \in \Sigma\) and \(E\) is visible to \(G\) in \(A\), then \(E \in \Sigma\)).

The operation Three takes a Three-appropriate tuple \((A, B, \Sigma)\) and returns a Three-appropriate tuple

\[ (A', B', \Sigma') = \text{Three}(A, B, \Sigma), \]

defined as follows.

If there are no \(A\)-unresolved \(\hat{\cdot}\) units in \(\Sigma\), then \((A', B', \Sigma') = (A, B, \Sigma)\).

Otherwise, let

\[ (\hat{\cdot} E_1, G_1, \vec{T}_1), (\hat{\cdot} E_2, G_2, \vec{T}_2), (\hat{\cdot} E_3, G_3, \vec{T}_3), \ldots \]  \hspace{1cm} (24)

be a list — generated according to some fixed choice function — of all triples \((\hat{\cdot} E, G, \vec{T})\), where \(\hat{\cdot} E\) is an \(A\)-unresolved unit of \(\Sigma\), \(G \in \Sigma\), and \(\vec{T}\) is a generalized domination chain type.

We first define the pillarings \(C_0, C_1, C_2, \ldots\) as follows:

- \(C_0 = \emptyset\) (remember from Section 9.1 that \(\emptyset\) is the trivial pillarings);
- \(C_{i+1} = \text{Two}(A, B, C_i, \vec{T}_i, \hat{\cdot} E_i, G_i, \Sigma)\).

It is obvious that the trivial pillarings is concordant with every resolution. So, \(C_0\) is concordant with \(B\). In view of clause 4 of Lemma 9.10 by induction on \(i\), we further see that each of the above pillarings \(C_i\) is concordant with \(B\) and hence \(C_{i+1}\) is well defined.

We now define the resolution \(A'\) as follows:

- For every \(A\)-unresolved element \(\hat{\cdot} E\) of \(\Sigma\), \(A'(\hat{\cdot} E) = x\), where \(x\) is an element of \(\text{Lim}(B(\hat{\cdot} E))\) — selected according to some fixed choice function — such that, for each \(i \geq 0\), the (unique) \(C_i\)-pillar of \(\hat{\cdot} E\) is a prefix of \(x\). In view of clauses 1, 4 and 5 of Lemma 9.10 such \(x\) exists.
- For all other units \(\hat{\cdot} H\), \(A'(\hat{\cdot} H) = A(\hat{\cdot} H)\).

Observe that

\[ A' \text{ is an extension of } A. \]  \hspace{1cm} (25)

Next, we define the pruning \(B'\) by stipulating that, for any unit \(\hat{\cdot} E\), we have:

- If \(\hat{\cdot} E \in \Sigma\), then \(B'(\hat{\cdot} E) = B(\hat{\cdot} E)\).
- Otherwise, \(B'(\hat{\cdot} E) = \{\epsilon\} \cup C_1(\hat{\cdot} E) \cup C_2(\hat{\cdot} E) \cup C_3(\hat{\cdot} E) \cup \ldots\) .

Finally, we define the set \(\Sigma'\) to be the closure of \(\Sigma\) under visibility in \(A'\). In view of Lemma 7.7, \(\Sigma'\) is countable.

\[ ^{10} \text{That } B \text{ is indeed a pruning will be verified in Lemma 9.11} \]
Lemma 9.11 Assume \((A, B, \Sigma)\) is a Three-appropriate tuple, and \((A', B', \Sigma') = \text{Three}(A, B, \Sigma)\). Then:

1. \(B'\) is a pruning such that, for every unit \(\triangleleft E\), \(B' (\triangleleft E) \subseteq B (\triangleleft E)\).
2. Where \(C_0, C_1, C_2, \ldots\) are as defined above, for each \(i \geq 0\) we have \(\mathbb{F}_1^{A'B'} \subseteq \mathbb{F}_1^{ABC}\).

Proof. Assume the conditions of the lemma. Let \(C_0, C_1, C_2, \ldots\) be as defined earlier in this section.

Clause 1: Consider an arbitrary unit \(\triangleleft E\). We want to show that \(B' (\triangleleft E)\) is a pruner (so that \(B'\) is indeed a pruning as promised), and that \(B' (\triangleleft E) \subseteq B (\triangleleft E)\). If \(\triangleleft E \in \Sigma\), then \(B' (\triangleleft E)\) is the same as \(B (\triangleleft E)\), and (taking into account that \(B (\triangleleft E)\) is a pruner) we are done. Now assume \(\triangleleft E \notin \Sigma\). By our definition of \(B'\), \(B' (\triangleleft E)\) contains \(\epsilon\). Next, consider any bitstring \(u\) such that \(u\) is a prefix of some element of \(B' (\triangleleft E)\). Obviously there is a number \(i\) and a bitstring \(w\) such that \(u \preceq w\) and \(w \in C_i (\triangleleft E)\). But observe from the construction of \(\Sigma\) that \(\triangleleft E \in \Sigma\), for a certain \(w\) with \(u \preceq w\) and hence of \(u \preceq w\), the strings \([w']^0\) and \([w']^1\) are among the \(C_{i+1}\)-pillars of \(\triangleleft E\), and therefore are among the elements of \(B' (\triangleleft E)\). This is exactly what it takes for \(B' (\triangleleft E)\) to be a pruner. Next, relying on clause 4 of Lemma 9.10 by induction on \(j\), we find that each \(C_j (j \geq 0)\) is concordant with \(B\), meaning that \(C_j (\triangleleft E) \subseteq B (\triangleleft E)\). Since every element of \(B' (\triangleleft E)\) other than \(\epsilon\) is an element of \(C_j (\triangleleft E)\) for some \(j \geq 0\), we find that \(B' (\triangleleft E) \subseteq B (\triangleleft E)\).

Clause 2: Consider an arbitrary \(i \geq 0\). For a contradiction, assume \(\mathbb{F}_1^{A'B'}\) is not a subset of \(\mathbb{F}_1^{ABC}\). Let \(G\) be a unit with \(G \in \mathbb{F}_1^{A'B'}\) and \(G \notin \mathbb{F}_1^{ABC}\). We may assume that all proper superunits of \(G\) are in \(\mathbb{F}_1^{ABC}\). By \([25]\) and clause 1 of the present lemma, \(\mathbb{F}_1^{A'B'} \subseteq \mathbb{F}_1^{ABC}\) so that \(G \in \mathbb{F}_1^{ABC}\). It is therefore obvious that the only possible reason why we still have \(G \notin \mathbb{F}_1^{ABC}\) is that \(G = \overline{E}\), \(y\) is a child of some \(A\)-unresolved unit \(\triangleleft E = \overline{E (x)}\) such that \(y\) is not comparable with any of the \(C_i\)-pillars of \(\triangleleft E\). This immediately rules out the possibility that \(\triangleleft E \in \Sigma\), because then, from the way we defined the resolution \(A'\) it is clear that \(G\) cannot be in \(\mathbb{F}_1^{A'B'}\). So, \(\triangleleft E \notin \Sigma\). Notice that then \(\triangleleft E\) is \(A\)-unresolved. Therefore, since \(G \in \mathbb{F}_1^{ABC}\), we have \(y \in \text{Lim}(B' (\triangleleft E))\). The latter implies that there are infinitely many prefixes \(w_1 \preceq w_2 \preceq w_3 \preceq \ldots\) of \(y\) that are elements of \(B' (\triangleleft E)\). Pick a \(w_j\) among these prefixes such that \(w_j\) is longer than any of the \(C_i\)-pillars of \(\triangleleft E\). In view of clause 5 of Lemma 9.10 it is obvious that one of the \(C_i\)-pillars of \(\triangleleft E\) should be a prefix of \(w_j\). But then \(y\) is comparable with such a pillar, which is a contradiction. 

Lemma 9.12 Assume \((A, B, \Sigma)\) is a Three-appropriate tuple, \(\triangleleft E\) is an \(A\)-unresolved element of \(\Sigma\), and \(G\) is an element of \(\Sigma\). Then, where \((A', B', \Sigma') = \text{Three}(A, B, \Sigma)\), we have:

1. \(\triangleleft E\) is \(A'\)-resolved, and \(A' (\triangleleft E) \in \text{Lim}(B (\triangleleft E))\).
2. \(\triangleleft E\) does not dominate \(G\) in \(\mathbb{F}_1^{A'B'}\).

Proof. Assume the conditions of the lemma. Clause 1 is obvious from the way the resolution \(A'\) is defined. To prove clause 2, for a contradiction, assume \(\triangleleft E \subseteq \triangleleft E\) dominates \(G\) in \(\mathbb{F}_1^{A'B'}\).

First, assume the reason for \(\triangleleft E\) dominating \(G\) in \(\mathbb{F}_1^{A'B'}\) is that \(G\) is a proper subunit of \(\triangleleft E\). Let \(i\) be the number such that, for the corresponding triple \((\triangleleft E_i, G_i, \overline{T_i})\) from the list \([24]\) we have \(\triangleleft E_i = \triangleleft E\), \(G_i = G\) and \(\overline{T_i}\) is empty. From clause 3 of Lemma 9.10 we find that \(\mathbb{F}_1^{ABC_{i+1}}\) does not contain \(G\). Therefore, in view of clause 2 of Lemma 9.11 \(\mathbb{F}_1^{A'B'}\) does not contain \(G\) either. But this is a contradiction because, if \(G\) is not in a given unit tree, it cannot be dominated (by whatever) in that tree.

Now assume the reason for \(\triangleleft E\) dominating \(G\) in \(\mathbb{F}_1^{A'B'}\) is that there is a \(\triangleleft E\)-over-\(G\) domination chain \(\overline{D}\) in \(\mathbb{F}_1^{A'B'}\). Let \(\overline{T}\) be the type of \(\overline{D}\). Let \(i\) be the number such that, for the corresponding triple \((\triangleleft E_i, G_i, \overline{T_i})\) from \([24]\) we have \(\triangleleft E_i = \triangleleft E\), \(G_i = G\) and \(\overline{T_i} = \overline{T}\). From clause 2 of Lemma 9.10 we find that there is no \(\triangleleft E\)-over-\(G\) domination chain of type \(\overline{T}\) in \(\mathbb{F}_1^{ABC_{i+1}}\). That is, \(\overline{D}\) is not a domination chain in \(\mathbb{F}_1^{ABC_{i+1}}\). Since, on the other hand, \(\overline{D}\) is a domination chain in \(\mathbb{F}_1^{A'B'}\), we find that there is a unit \(H\) in \(\overline{D}\) such that \(H \in \mathbb{F}_1^{A'B'}\) but not \(H \in \mathbb{F}_1^{ABC_{i+1}}\). However, by clause 2 of Lemma 9.11 this is impossible. 

\[\text{Lemma 9.11}\]
9.7 The operation Four

The operation Four takes a pair \((A, J)\) such that \(A\) is a resolution and \(J\) is a politer unit of \(F_1^A\), and returns a resolution

\[ \mathcal{R} = \text{Four}(A, J). \]

To construct such a resolution \(\mathcal{R}\), we define the infinite sequence

\[ (A_0, B_0, \mathcal{T}_0), (A_1, B_1, \mathcal{T}_1), (A_2, B_2, \mathcal{T}_2), \ldots \]

of Three-appropriate tuples as follows.

- \(A_0 = A, B_0 = \text{the trivial pruning } \emptyset, \text{ and } \mathcal{T}_0 = \text{the closure of the set } \{J\} \text{ under visibility in } A. \)
  The countability of \(\mathcal{T}_0\) is guaranteed by Lemma 7.7.

- \((A_{i+1}, B_{i+1}, \mathcal{T}_{i+1}) = \text{THREE}(A_i, B_i, \mathcal{T}_i)\).

Now, we define \(\mathcal{R}\) as the union (see Section 9) of the resolutions \(A_0, A_1, A_2, \ldots\). Such a union is well defined because, in view of (25), each \(A_{i+1}\) is an extension of \(A_i\), and hence the resolutions \(A_0, A_1, A_2, \ldots\) are pairwise consistent. It is also clear that

\[ \mathcal{R} \text{ is an extension of } A, \text{ as well as of each } A_i (i \geq 0). \] (26)

For subsequent references, we also define \(\mathbb{T}\) as the union of the sets \(\mathcal{T}_0, \mathcal{T}_1, \mathcal{T}_2, \ldots\). It is rather obvious that \(\mathbb{T}\) is closed under visibility in \(\mathcal{R}\).

Henceforth we shall refer to the earlier-stated assumptions on the parameters \(A, J\) and the definitions of the parameters \(A_i, B_i, \mathcal{T}_i, \mathcal{R}, \mathbb{T}\) as the construction of Four.

Lemma 9.13 Let all parameters be as in the construction of Four. Further, let \(i\) be a natural number, \(G\) any element of \(\mathcal{T}_i\), and \(E\) any unit that dominates \(G\) in \(F^R_1\). Then we have:

1. \(E \in \mathbb{T}\);
2. \(E\) is \(\mathcal{R}\)-resolved;
3. \(E\) dominates \(G\) in \(F^{A_{i+1}B_{i+1}}_1\).

Proof. Assume the conditions of the lemma.

Clause 1: If the reason for \(E\) dominating \(G\) in \(F^R_1\) is that \(G\) is a proper subunit of \(E\), then, by clause 1 of Lemma 7.12, \(E\) is visible to \(G\) in \(A_i\). But \(\mathcal{T}_i\) is closed under visibility in \(A_i\), so \(E \in \mathcal{T}_i\).

Now assume the reason for \(E\) dominating \(G\) in \(F^R_1\) is that there is a \(E\)-over-\(G\) domination chain

\[ L_1, M_1, X_1, \ldots, L_n, M_n, X_n \] (27)

in \(F^R_1\). Thus, \(M_n\) drives \(G\).

Let \(E_1, \ldots, E_d\) be all \(A_i\)-unresolved \(E\)-superunits of \(M_n\) that happen to be subunits of \(X_n\). Here we assume that \(E_1\) is a proper superunit of \(E_2\), \(E_2\) is a proper superunit of \(E_3\), etc. Obviously \(E_1\) strictly drives \(G\) (through \(X_n\)) and hence \(E_1\) is visible to \(G\) in \(A_i\). This implies that \(E_1 \in \mathcal{T}_i\), because \(\mathcal{T}_i\) is closed under visibility in \(A_i\). Therefore, by clause 1 of Lemma 7.12, \(E_1\) is \(A_{i+1}\)-resolved. Then, by (26), \(E_1\) is also \(\mathcal{R}\)-resolved, and the \(\mathcal{R}\)-resolvent of \(E_1\) is the same as the \(A_{i+1}\)-resolvent of \(E_1\). But \(E_2\) has to be a subunit of the \(\mathcal{R}\)-resolvent of \(E_1\) (otherwise we would have \(M_n \notin F^R_1\) and, for this reason, (27) would not be a domination chain in \(F^R_1\)). So, \(E_2\) is a subunit of the \(A_{i+1}\)-resolvent of \(E_1\). This obviously makes \(E_2\) visible to \(G\) in \(A_{i+1}\) (namely, \(E_2\) \(A_{i+1}\)-strictly drives \(G\) through \(X_n\)). By using similar reasoning to the above (and with Lemma 7.13 in mind), we now find that \(E_2\) \(\in \mathcal{T}_{i+1}\), \(E_2\) is \(A_{i+2}\)-resolved and \(E_3\) is a subunit of the \(A_{i+2}\)-resolvent of \(E_2\), which makes \(E_3\) visible to \(G\) in \(A_{i+2}\), and so on. This way, we eventually find that \(M_n\) is visible to \(G\) in \(A_{i+d}\) and thus \(M_n \in \mathcal{T}_{i+d}\) and hence \(M_n \in \mathcal{T}\). By Lemma 7.9, \(M_n\) is also visible to \(G\) in \(\mathcal{R}\), because \(\mathcal{R}\) is an extension of \(A_{i+d}\).

The visibility of \(M_n\) to \(G\) in \(\mathcal{R}\), of course, also implies the visibility if \(L_n\) to \(G\) in \(\mathcal{R}\), because \(M_n\) and
condition

Re-examining our argument in the previous paragraph, we see that it goes through for clause 1 of the present lemma, \( A_1 \) of Lemma 9.12, we also have

\[ y = \circ \]

that, on the other hand, be that there is an \( F \) chain in \( \circ 1 \) of Lemma 7.8, \( L \) sufficient to show that all of the units \( \circ \)

because, in the process of applying \( R \) is an extension of \( A_j \). And if \( E \) is \( A_j \)-unresolved, then, in view of clause 1 of Lemma 9.12 \( E \) is \( A_j+1 \)-resolved, and hence, again by (20), it is also \( R \)-resolved.

\[ \text{Clause 3: According to the conditions of our lemma, } \circ E \text{ dominates } G \text{ in } F^R \text{, which, by the definition of domination, implies that both } \circ E \text{ and } G \text{ are in } F^R_1. \]

We first examine \( G \). For a contradiction, assume \( G \notin F^A_{1} \). Since \( G \in F^R \) and \( R \) is an extension of \( A_{i+1} \), we have \( G \in F^A_{1} \). Therefore, the only reason for \( G \notin F^A_{1} \) can be that there is an \( A_{i+1} \)-unresolved unit \( \circ H = \circ H[x] \) of \( F^R \) and \( F^A_{1} \) and a child \( \circ H \circ [x, y] \) of \( \circ H \circ [x] \) such that \( G \) is a subunit of \( \circ H \circ [x, y] \) but \( \circ H \circ [x, y] \notin F^A_{1} \), meaning that \( y \notin \text{Lim}(B_{i+1}(\circ H)) \). By clause 1 of Lemma 7.8 \( \circ H \) is visible to \( G \) in \( A_{i+1} \). Therefore, as \( \circ E \) is closed under visibility in \( A_{i+1} \), we have \( \circ H \in \circ E \). Hence, by clause 1 of Lemma 9.12 \( \circ H \) is \( A_{i+2} \)-resolved and \( A_{i+2}(\circ H) \in \text{Lim}(B_{i+1}(\circ H)) \). But, since \( R \) is an extension of \( A_{i+2} \) and \( y = R(\circ H) \) (otherwise \( G \) would not be in \( F^R_1 \)), we have \( A_{i+2}(\circ H) = y \). Thus, \( y \in \text{Lim}(B_{i+1}(\circ H)) \), contradicting the earlier established \( y \notin \text{Lim}(B_{i+1}(\circ H)) \).

We now examine \( \circ E \), and assume \( \circ E \notin F^A_{1} \). In the preceding case, since \( \circ E \in F^R \) and \( R \) is an extension of \( A_{i+1} \), we have \( \circ E \in F^A_{1} \). Therefore, the only reason for \( \circ E \notin F^A_{1} \) can be that there is an \( A_{i+1} \)-unresolved unit \( \circ H = \circ H[x] \) of \( F^R \) and \( F^A_{1} \) and a child \( \circ H \circ [x, y] \) of \( \circ H \circ [x] \) such that \( \circ E \) is a subunit of \( \circ H \circ [x, y] \) but \( \circ H \circ [x, y] \notin F^A_{1} \), meaning that \( y \notin \text{Lim}(B_{i+1}(\circ H)) \). By clause 1 of the present lemma, \( \circ E \in \circ E \) for some \( j \). By clause 1 of Lemma 9.12 \( \circ H \) is visible to \( \circ E \) in \( A_{i+1} \). Therefore, as \( \circ E \) is closed under visibility in \( A_{i+1} \), we have \( \circ H \in \circ E \). We may assume that \( j \) is the smallest number with \( \circ H \in \circ E \). Obviously \( \circ H \) is \( A_{j+1} \)-unresolved because, in the process of applying FOUR, an \( A_{i+1} \)-unresolved \( \circ \)-unit becomes \( A_{i+1} \)-resolved (if and only if that unit is in \( \circ E \)). Therefore, by clause 1 of Lemma 9.12 \( \circ H \) is \( A_{j+1} \)-resolved. Remember that, on the other hand, \( \circ H \) is \( A_{i+1} \)-unresolved. This clearly implies that \( i + 1 < j + 1 \). By clause 1 of Lemma 9.12 we also have \( A_{j+1}(\circ H) \in B_j(\text{Lim}(B_{i+1}(\circ H))) \). But, since \( R \) is an extension of \( A_{j+1} \) and \( y = R(\circ H) \), we have \( A_{j+1}(\circ H) = y \). Thus, \( y \in \text{Lim}(B_j(\circ H)) \). At the same time, since \( i + 1 < j \), in view of clause 1 of Lemma 9.11 we have \( B_j \subseteq B_{i+1} \) and hence \( \text{Lim}(B_j(\circ H)) \subseteq \text{Lim}(B_{i+1}(\circ H)) \). Thus, \( y \in \text{Lim}(B_{i+1}(\circ H)) \). This, however, contradicts the earlier established \( y \notin \text{Lim}(B_{i+1}(\circ H)) \).

Now assume the reason for \( \circ E \) dominating \( G \) in \( F^R \) is that there is a \( \circ E \)-over-\( G \) domination chain in \( F^R \). Namely, we may assume that (27) is such a chain. In order to show that \( \circ E \) also dominates \( G \) in \( F^A_{1} \), it is sufficient to show that both \( \circ E \) and \( G \) are in \( F^A_{1} \) and that (27) is a \( \circ E \)-over-\( G \) domination chain in \( F^R_1 \). In turn, in order to show that (27) is a \( \circ E \)-over-\( G \) domination chain in \( F^R_1 \), it is sufficient to show that all of the units \( \circ L_1, M_1, \ldots, L_n, M_n \) are in \( F^A_{1} \). So, consider any \( Z \) with

\[ Z \in \{ \circ E, G, L_1, M_1, \ldots, L_n, M_n \}. \]

Re-examining our argument in the previous paragraph, we see that it goes through for \( Z \) in the role of \( \circ E \) as long as \( Z \) is in \( T \). But \( Z \) is indeed in \( T \): if \( Z = G \), then the fact \( Z \in T \) is immediate from the condition \( G \in \circ E \) of the present lemma; otherwise, the fact \( Z \in T \) follows from (28). □
Lemma 9.14 Let all parameters be as in the construction of FOUR. Further, let \( i \) be a natural number, \( G \) any element of \( \mathcal{T}_i \), and \( \triangle E \) any \( A_i \)-unresolved unit. Then \( \triangle E \) does not dominate \( G \) in \( \Phi_1^R \).

Proof. Assume the conditions of the lemma. For a contradiction, also assume that \( \triangle E \) dominates \( G \) in \( \Phi_1^R \). By clause 1 of Lemma 9.13 we have \( \triangle E \in \mathcal{T}_j \), meaning that \( \triangle E \in \mathcal{T}_j \) for some \( j \). We may assume that \( j \) is the smallest number with \( \triangle E \in \mathcal{T}_j \). Obviously \( \triangle E \) is \( A_i \)-unresolved because, as observed in the proof of Lemma 9.13 in the construction of FOUR, an \( A_i \)-unresolved \( \triangle \)-unit becomes \( A_{i+1} \)-resolved only when the unit is in \( \mathcal{T}_j \). By clause 1 of Lemma 9.12 \( \triangle E \) is \( A_{i+1} \)-resolved. This implies that \( j + 1 > i \) (otherwise \( \triangle E \) would be \( A_i \)-resolved). So, since \( G \in \mathcal{T}_i \), we also have \( G \in \mathcal{T}_j \).

Now, in view of clause 2 of Lemma 9.12 \( \triangle E \) does not dominate \( G \) in \( \Phi_1^{A_{i+1}B_{i+1}} \). This, in turn, by clause 3 of Lemma 9.13 implies that \( \triangle E \) does not dominate \( G \) in \( \Phi_1^R \), which is a contradiction. \( \blacksquare \)

9.8 The resolution \( \mathcal{T} \) and its totality

It is well known that (ZFC proves that) every set can be well-ordered. So, let \( \prec \) be some fixed well-ordering of the set of all politeral units.

With each politeral unit \( J \) we associate a resolution \( \mathcal{T}_J \) defined by

\[
\mathcal{T}_J = \text{FOUR}(A_J, J),
\]

where \( A_J \) is the union of all resolutions \( \mathcal{T}_{J'} \) such that \( J' \prec J \).

Now, we define the ultimate resolution \( \mathcal{T} \) as the union of all resolutions \( \mathcal{T}_J \) associated with politeral units. In view of (26), such a union is well defined, because every \( \mathcal{T}_J \) is an extension of each \( \mathcal{T}_{J'} \) with \( J' \prec J \). Of course, we also have:

\[
\text{For each politeral unit } J, \mathcal{T} \text{ is an extension of } \mathcal{T}_J. \tag{29}
\]

We claim that \( \mathcal{T} \) is a total resolution, as promised in Lemma 9.1. Indeed, for a contradiction, assume \( \mathcal{T} \) is not total. Let \( \triangle E \) be a \( \mathcal{T} \)-unresolved \( \triangle \)-unit of \( \Phi_1^R \). Pick any politeral unit \( J \) among the subunits of \( \triangle E \). Let \( A \) be the union of all resolutions \( \mathcal{T}_{J'} \) with \( J' \prec J \). Since, by (29), \( \mathcal{T} \) is an extension of \( A \), \( \triangle E \) is \( A \)-unresolved. Let, along with our present \( A \) and \( J \), the parameters \( A_i, B_i, \mathcal{T}_i, R \) be as in the construction of FOUR. Of course, \( J \in \mathcal{T}_0 \) and \( \triangle E \) dominates \( J \) in \( \Phi_1^R \). But then, by clause 2 of Lemma 9.13 \( \triangle E \) is \( R \)-resolved and thus also \( \mathcal{T} \)-resolved. This is a contradiction.

9.9 Proof of clause (i) of Lemma 9.1

Let \( J \) be the \( \prec \)-smallest of all politeral units of \( \Phi_1^T \). For a contradiction, assume \( \triangle E \) is a unit that dominates the root \( F_0[] \) of \( \Phi_1^T \) in \( \Phi_1^R \). Of course, the reason for this domination cannot be that \( F_0[] \) is a proper subunit of \( \ triangle E \), because \( F_0[] \) is not a subunit of anything but itself. Let

\[
L_1, M_1, X_1, \ldots, L_n, M_n, X_n
\]

be a \( \triangle E \)-over-\( F_0[] \) domination chain in \( \Phi_1^T \). So, \( M_n \) drives \( F_0[] \). Let \( i \) be the smallest number among \( 1, \ldots, n \) such that \( M_i \) drives \( F_0[] \). Since \( M_i \) drives \( F_0[] \), \( M_i \) has no \( \triangle \)-superunits. Therefore, obviously, \( M_i \) drives \( J \) as, by the way, it drives any other unit. But then, where \( Y \) is the smallest common superunit of \( M_i \) and \( J \), the following sequence is a \( \triangle E \)-over-\( J \) domination chain in \( \Phi_1^T \):

\[
L_1, M_1, X_1, \ldots, L_i, M_i, Y.
\]

Thus,

\[
\triangle E \text{ dominates } J \text{ in } \Phi_1^T. \tag{30}
\]

Let \( A \) be the trivial resolution, and let this \( A \), along with all other parameters, be as in the construction of FOUR. Note that \( \triangle E \) (as any other \( \triangle \)-unit) is \( A_0 \)-unresolved, and \( J \) is (of course) an element of \( \mathcal{T}_0 \). Hence, by Lemma 9.13 \( \triangle E \) does not dominate \( J \) in \( \Phi_1^R \). Since \( \mathcal{T} \) is an extension of \( R \), \( \triangle E \) does not dominate \( J \) in \( \Phi_1^T \), either. This, however, contradicts (30).
9.10 Proof of clause (ii) of Lemma 9.1

Consider any units \( E \) and \( G \) of \( F^T \). Our goal is to show that they do not dominate each other in \( F^T \). For a contradiction, deny this.

Since the resolution \( T \) is total, both \( E \) and \( G \) have to be \( T_{J'} \)-resolved for some politeral unit \( J \). Assume \( J \) is the \( \prec \)-smallest of all politeral units such that at least one of the units \( E \), \( G \) is \( T_{J'} \)-resolved. Let \( A \) be the union of all resolutions \( T_{J'} \) with \( J' \prec J \). Let this \( A \) (= \( A_0 \)) and all other parameters be as in the construction of FOUR. Let \( i \) be the smallest number such that one of the units \( E \), \( G \) is \( A_i \)-resolved. Namely, we may assume that \( G \) is the one (or at one) of the two units that is \( A_i \)-resolved. Note that \( i > 0 \), and that \( G \in \mathcal{T}_{i-1} \) (otherwise the \( A_{i-1} \)-unresolved \( G \) would not have become \( A_i \)-resolved). At the same time, \( E \in \mathcal{A}_{i-1} \)-unresolved. Therefore, by Lemma 9.14, \( E \) does not dominate \( G \) in \( F^T \), and hence \( E \) does not dominate \( G \) in \( F^T \) either. This is however a contradiction.

9.11 Proof of clause (iii) of Lemma 9.1

Throughout this proof, “dominates” is to be understood as “dominates in \( F^T \)”. Similarly for “domination chain”. Assume \( E \), \( G \) and \( H \) are units of \( F^T \), \( E \) dominates \( G \), and \( G \) dominates \( H \). Our goal is to show that \( E \) dominates \( H \). We need to consider the following cases.

Case 1: The reason for \( E \)-over-\( G \) domination is that there is a \( E \)-over-\( G \) domination chain

\[
L_1, M_1, X_1, \ldots, L_n, M_n, X_n. \quad (31)
\]

Subcase 1.1: The reason for \( G \) dominating \( H \) is that there is a \( G \)-over-\( H \) domination chain

\[
L'_1, M'_1, X'_1, \ldots, L'_{n'}, M'_{n'}, X'_{n'}. \quad (32)
\]

For notational convenience, let us agree that

\[
H = L'_{n'+1}.
\]

Subsubcase 1.1.1: No \( M'_i \) (1 \( \leq i \leq n' \)) is a subunit of \( E \).

Subsubsubcase 1.1.1: No \( M_i \) (1 \( \leq i \leq n \)) drives any \( L'_j \) (1 \( \leq j \leq n' + 1 \)). From the fact that \( 31 \) is a \( E \)-over-\( G \) domination chain, we know that \( M_n \) drives \( G \). From the fact that \( 32 \) is a \( G \)-over-\( H \) domination chain, we also know that \( L'_1 \) is a subunit of \( G \). Hence, by Lemma 6.3, \( M_n \) drives \( L'_1 \). But then, where \( Y \) is the smallest common superunit of \( M_n \) and \( L'_1 \), the following is clearly a \( E \)-over-\( H \) domination chain:

\[
L_1, M_1, X_1, \ldots, L_n, M_n, Y, L'_1, M'_1, X'_1, \ldots, L'_{n'}, M'_{n'}, X'_{n'}.
\]

Subsubcase 1.1.1.2: Some \( M_i \) (1 \( \leq i \leq n \)) drives one of \( L'_j \) (1 \( \leq j \leq n' + 1 \)). We may assume that \( i \) is the smallest number such that \( M_i \) drives one of \( L'_j \), and that \( j \) is the greatest number such that \( M_i \) drives \( L'_j \). But note that then, where \( Y \) is the smallest common superunit of \( M_i \) and \( L'_j \), the following is a \( E \)-over-\( H \) domination chain:

\[
L_1, M_1, X_1, \ldots, L_i, M_i, Y, L'_j, M'_j, X'_j, \ldots, L'_{n'}, M'_{n'}, X'_{n'}.
\]

Subsubcase 1.1.2: Some \( M'_i \) (1 \( \leq i \leq n' \)) is a subunit of \( E \). We may assume that \( i \) is the greatest such number.

First, suppose \( M'_i \) drives \( E \). Let \( j \) be the smallest number among 1, \( \ldots \), \( i \) such that \( M'_j \) drives \( E \), and \( Y \) be the smallest common superunit of \( M'_j \) and \( E \). Then

\[
L'_1, M'_1, X'_1, \ldots, L'_j, M'_j, Y
\]

is a \( G \)-over-\( E \) domination chain, meaning that \( G \) dominates \( E \). But this is impossible due to the already proven clause (ii) of Lemma 9.1.
Now suppose \(M'\) does not drive \(\mathcal{E}\), meaning that \(M'\) has a \(\mathcal{E}\)-superunit that happens to be a subunit of \(\mathcal{E}\). On the other hand, \(M'\) drives \(L'_{i+1}\). This obviously implies that \(L'_{i+1}\) is a proper subunit of \(\mathcal{E}\).

But then we have: (1) if \(i = n'\), then \(H = \{L'_{n'+1}\}\) is a proper subunit of \(\mathcal{E}\) and hence \(\mathcal{E}\) dominates \(H\); and (2) if \(i < n'\), then the following is a \(\mathcal{E}\)-over-\(H\) domination chain:

\[
L'_{i+1}, M'_{i+1}, X'_{i+1}, \ldots, L'_n, M'_n, X'_n.
\]

Subcase 1.2: The reason for \(\mathcal{E}\) dominating \(H\) is that the latter is a proper subunit of the former.

Subsubcase 1.2.1: None of the units \(M_1, \ldots, M_{n-1}\) drives \(H\). By Lemma 6.2, \(\mathcal{E}\) drives \(H\). From the fact that \(\mathcal{E}\) is a \(\mathcal{E}\)-over-\(\mathcal{E}\) domination chain, we also know that \(M_n\) drives \(\mathcal{E}\). Hence, by clause 1 of Lemma 6.3, \(M_n\) drives \(H\). But then, where \(Y\) is the smallest common superunit of \(M_n\) and \(H\), the following is a \(\mathcal{E}\)-over-\(H\) domination chain:

\[
L_1, M_1, X_1, \ldots, L_n, M_n, Y.
\]

Subsubcase 1.2.2: One of the units \(M_i\) with \(1 \leq i < n\) drives \(H\). We may assume that \(i\) is the smallest such number. But then, where \(Y\) is the smallest common superunit of \(M_i\) and \(H\), the following is a \(\mathcal{E}\)-over-\(H\) domination chain:

\[
L_1, M_1, X_1, \ldots, L_i, M_i, Y.
\]

Case 2: The reason for \(\mathcal{E}\) dominating \(\mathcal{E}\) is that the latter is a proper subunit of the former.

Subcase 2.1: The reason for \(\mathcal{E}\) dominating \(H\) is that there is a \(\mathcal{E}\)-over-\(H\) domination chain. Let \(E\) be such a chain. If none of \(M'_i\) \((1 \leq i \leq n')\) is a subunit of \(\mathcal{E}\), then the same chain is a \(\mathcal{E}\)-over-\(H\) domination chain. And if some \(M'_i\) \((1 \leq i \leq n')\) is a subunit of \(\mathcal{E}\), then we reason as in Subsubcase 1.1.2 and find that \(\mathcal{E}\) dominates \(H\).

Subcase 2.2: The reason for \(\mathcal{E}\) dominating \(H\) is that the latter is a proper subunit of the former. Then \(H\) is a proper subunit of \(\mathcal{E}\), and hence \(\mathcal{E}\) dominates \(H\).

10 Hyperformulas and hypercirkvenents

In addition to the language of \(\text{CL15}\), in this section we consider an infinitary propositional language with the logical vocabulary \(\{\neg, \wedge, \vee\}\) and a continuum of atoms. Atoms (resp. literals, formulas) of this language will be referred to as “hyperatoms” (resp. “hyperliterals”, “hyperformulas”).

Namely, every hyperatom is a triple \((P, A, B)\), where \(P\) is an atom of the language of \(\text{CL15}\), and \(A\) and \(B\) are sets of natural numbers (and vice versa: every such triple is a hyperatom). Next, every hyperliteral is either \(\alpha\) (a positive hyperliteral) or \(\neg\alpha\) (a negative hyperliteral), where \(\alpha\) is a hyperatom. Two hyperliterals are said to be opposite if one is \(\alpha\) and the other is \(\neg\alpha\) for some hyperatom \(\alpha\). Finally, hyperformulas are defined inductively as follows:

(a) Every hyperatom is a hyperformula.

(b) Whenever \(\alpha\) is a hyperformula, so is \(\neg\alpha\).

(c) Whenever \(S\) is a (not necessarily finite or even countable) set of hyperformulas, so are \(\wedge S\) and \(\vee S\).

(d) Nothing is a hyperformula unless it can be obtained by repeated applications of (a), (b) and (c).

A subhyperformula in the context of hyperformulas means the same as a subformula in the context of formulas.

What we call a hypermodel is nothing but a truth assignment for hyperformulas, i.e., a function \(h\) that sends every hyperatom \(\alpha\) to one of the values true or false, and extends to all hyperformulas in the standard way. When the value of \(h\) at a hyperformula \(\alpha\) is true, we say that \(\alpha\) is true under \(h\), or that \(h\) makes \(\alpha\) true. Similarly for “false”. A hyperformula \(\alpha\) is said to be satisfiable iff there is a hypermodel that makes it true; otherwise it is unsatisfiable. And a hyperformula \(\alpha\) is a tautology, or is tautological, iff every hypermodel makes it true.
A positive (resp. negative) occurrence of a hyperatom in a hyperformula is an occurrence that is in the scope of even (resp. odd) number of occurrences of \(\neg\). Now, we say that a hyperformula \(\alpha\) is binary iff every hyperatom has at most one positive and at most one negative occurrence in it. A hyperformula \(\alpha\) is a binary tautology iff it is both binary and tautological.

In the context of the run \(\Omega\) fixed in Section 5 with each politeral unit \(L\) we associate a hyperliteral \(L^\circ\). Namely, let \(\Theta_L\) be the projection of \(\Omega\) on \(L\), we let \(A_L\) and \(B_L\) be the following sets of natural numbers:

\[
A_L = \{ a \mid \Theta_L \text{ contains the labmove } \top a \};
\]
\[
B_L = \{ b \mid \Theta_L \text{ contains the labmove } \bot b \}.
\]

In other words, \(A_L\) is the set of natural numbers enumerated by \(E\)'s adversary in \(L\), and \(B_L\) is the set of natural numbers enumerated by \(E\). Then, where \(P\) is the atom of the language of \(\text{CL15}\) such that \(\tilde{L} = P\) (resp. \(\tilde{L} = \neg P\)), we stipulate that \(L^\circ\) is the hyperliteral \((P, A, B)\) (resp. \(\neg(P, B, A)\)).

**Lemma 10.1** Any two politeral units \(L\) and \(M\) are opposite iff so are the corresponding hyperliterals \(L^\circ\) and \(M^\circ\).

**Proof.** Straightforward. ■

We now turn the unit tree \(F_1\) into a hyperformula

\[ F_1 \]

as follows. \(F_1\) can be viewed as a tree where every node is labeled with (rather than is) a (the corresponding) unit. Then \(F_1\) is a hyperformula which — more precisely, whose parse tree — is obtained from \(F_1\) through replacing every \(\land\)- or \(\lor\)-unit by \(\land\), every \(\lor\)- or \(\land\)-unit by \(\lor\), and every politeral unit \(L\) with the hyperliteral \(L^\circ\). Whenever a hyperformula \(\beta\) (together with all of its subhyperformulas) is obtained in this process through replacing a unit \(E\) (together with all of its subunits), we say that \(E\) is the unital origin of \(\beta\), and denote \(E\) by \(\text{Org}(\beta)\).

The hyperformula

\[ F_1 \]

and the function of unital origin for its subhyperformulas are defined in the same way, with the only difference that now the starting unit tree for applying the above-described replacements is \(F_1^T\) rather than \(F_1\). Note that, in view of the totality of the resolution \(T\), every conjunctive subhyperformula of \(F_1^T\) originating from a \(\lor\)-unit has a single conjunct. Thus, unlike disjunctive subhyperformulas (namely, those originating from \(\land\)-units), all conjunctive subhyperformulas of \(F_1^T\) have only finitely many (specifically, one or two) conjuncts.

In view of Lemmas [[7.1] and [10.1]], it is clear that

\[ F_1 \text{ is binary, and hence so is } F_1^T. \] (33)

In turn, from [[33]], it is clear that different occurrences of subhyperformulas in \(F_1\) or \(F_1^T\) are always different as hyperformulas; therefore, there is no need to maintain a terminological distinction between “subhyperformula” and “osubhyperformula”.

**Lemma 10.2** \(F_1\) is not tautological.

The rest of this section is devoted to a proof of Lemma [10.2]. For a contradiction, assume

\[ F_1 \text{ is tautological.} \] (34)

Observe that \(F_1^T\) is the result of deleting in \(F_1\) some conjuncts of some conjunctive subhyperformulas. The result of such a deletion obviously cannot destroy tautology. So, [34] immediately implies that

\[ F_1^T \text{ is tautological.} \] (35)
We now convert $\square F_0$ to its disjunctive normal form, which we denote by $F_2$. Namely, $F_2$ is obtained from $F_0$ in the standard way by repeatedly applying distributivity and changing every conjunction of disjunctions to an equivalent disjunction of conjunctions. It is not hard to see that such a hyperformula $F_2$ has a continuum of disjuncts (unless $F_0$ did not contain $\top$), where, however, each disjunct only has finitely many conjuncts. So, $F_2$ is in fact a disjunction of ordinary, “finitary” formulas of classical logic. $F_2$ is equivalent (in the standard classical sense) to $\square F_0$ and hence, just like the latter, is a tautology.

The tautology of $F_2$ means that $\neg F_2$ is unsatisfiable. Applying the standard DeMorgan conversions to $\neg F_2$, we turn it into an equivalent — and hence also unsatisfiable — hyperformula $F_3$, which is a (probably uncountably long) conjunction of finite disjunctions of hyperliterals. Let $S$ be the set of all conjuncts of $F_3$. Thus, $S$ is unsatisfiable. Then, by the compactness theorem, there is a finite subset $S'$ of $S$ which is unsatisfiable. This, in turn, means that there is an unsatisfiable hyperformula $F'_3$ which results from $F_3$ by deleting all but finitely many conjuncts. This, in turn, implies that there is a tautological hyperformula $F'_2$ which results from $F_2$ by deleting all but finitely many disjuncts.

Applying distributivity to $F'_2$, we get a tautological hyperformula

\[ F_4 \]

which is the result of deleting in $\square F_0$ all but finitely many disjuncts in all disjunctive subhyperformulas. For simplicity, we may (and will) assume that

\[ \text{every disjunctive subhyperformula of } F_4 \text{ has at least one disjunct} \]  
\[ (\text{otherwise, if all of the disjuncts of a disjunctive subhyperformula of } \square F_0 \text{ have been deleted, restore one — arbitrary — disjunct).} \]

Similarly, we may (and will) assume that

\[ \text{whenever } \beta \text{ is a subhyperformula of } F_4 \text{ such that } \text{Org}(\beta) \text{ is a } \lor\text{-unit, } \beta \text{ has two disjuncts.} \]

Thus, $F_4$ is a tautology of ordinary, “finitary” classical propositional logic. In view of (33), it is also binary.

The earlier defined function Org of unital origin extends from subhyperformulas of $\square F_0$ to those of $F_4$ in an obvious way. Namely, as noted just a while ago, every subhyperformula $\beta$ of $F_4$ is the result of deleting some disjuncts in some subdisjunctions of some subhyperformula $\beta'$ of $\square F_0$. Then the unital origin of $\beta$ is the same as that of $\beta'$.

We are now going to show that

\[ \text{CL15 } \vdash F_0. \]

The above statement directly contradicts our original assumption that CL15 $\not\vdash F_0$. And, as we remember, obtaining a contradiction (from assumption (34)) was the goal of the present proof. Thus, the only remaining task within our proof of Lemma 10.2 now is to verify (38).

Let us say that a cirquent $C$ is derivable (in CL15) from a cirquent $C'$ iff there is a sequence $C_1, \ldots, C_n$ of cirquents, called a derivation of $C$ from $C'$, such that $C_1 = C'$, $C_n = C$ and, for each $i \in \{1, \ldots, n-1\}$, $C_{i+1}$ follows from $C_i$ by one of the rules of CL15.

We construct a CL15-proof of $F_0$ bottom-up, starting from $F_0$ and moving from conclusions to premises. The whole construction consists of two main parts. During the first part, we apply the below-described procedure DERIVATION, which takes (starts with) $F_0$ — more precisely, the cirquent $F_0$ — and constructs a derivation of it from a certain cirquent $D$ all of whose oformulas are literals (Lemma 10.8). During the second part (Lemma 10.9), we continue our bottom-up construction of a proof from $D$ and hit an axiom, meaning that $D$ is provable in CL15 and hence so is $F_0$.

Here we slightly expand the earlier-introduced formalism of cirquents through allowing to prefix some (possibly all, possibly none) $\top$-oformulas of a cirquent by a $\sqrt{}$ (“check”). A $\top$-oformula of the form $\sqrt{} E$ will be said to be checked, and all other oformulas said to be unchecked. The presence or

---

\[ \text{The compactness theorem is known to hold not only for countable languages, but also for languages with uncountable sets of atoms.} \]
absence of the prefix \(\sqrt{}\) has no effect on the applicability of rules: from the perspective of (the rules of) **CL15**, an oformula \(\sqrt{\alpha}\) is treated as if it simply was \(\hat{\alpha}\).

At every step of our description of the procedure **DERIVATION**, \(C\) stands for the “current cirquent”, for which (as long as possible) we need to find a premise. \(C\) is initialized to \(F_0^\bigcirc\).

Next, **DERIVATION** maintains a one-to-one mapping that sends each oformula \(E\) of the “current cirquent” \(C\) to some subhyperformula \(\alpha\) of \(F_4\), with such an \(\alpha\) said to be the \(C\)-image of \(E\), or the image of \(E\) in \(C\), or simply the image of \(E\) when \(C\) is fixed or clear from the context, and denoted by

\[
\text{Img}^C(E).
\]

The image of the (only) oformula \(F_0\) of the initial cirquent \(F_0^\bigcirc\) is the hyperformula \(F_4\) itself. The mapping will be maintained in such a way that — as will be easily seen from our description of the procedure — we always have:

**Condition 10.3**

For any unchecked oformula \(H\) of \(C\), the \(F_0\)-origin of \(\text{Org}^C(\text{Img}^C(H))\) is \(H\); similarly, for any checked oformula \(\sqrt{\alpha}\) of \(C\), the \(F_0\)-origin of \(\text{Org}^C(\text{Img}^C(\sqrt{\alpha}))\) is \(H\). Consequently:

(i) where \(L\) is a literal, the image of the oformula \(L\) or \(\sqrt{L}\) is a hyperliteral (namely, a hyperliteral \(\alpha\) such that the \(F_0\)-origin of \(\text{Org}(\alpha)\) is \(L\));

(ii) the image of an oformula of the form \(E \land G\) or \(\sqrt{E} \land G\) is of the form \(\land \{\alpha, \beta\}\);

(iii) the image of an oformula of the form \(E \lor G\) or \(\sqrt{E} \lor G\) is of the form \(\lor \{\alpha, \beta\}\);

(iv) the image of an oformula of the form \(\check{E}\) or \(\sqrt{\check{E}}\) is of the form \(\land \{\alpha\}\);

(v) the image of an oformula of the form \(\hat{E}\) or \(\sqrt{\hat{E}}\) is of the form \(\lor \{\alpha_1, \ldots, \alpha_n\}\) for some \(n \geq 1\).

We refer to the (only) overgroup of the initial cirquent \(F_0^\bigcirc\) as the **master overgroup**. Every new (“non-master”) overgroup that will emerge during the procedure will be **labeled** with some \(\check{}\)-unit of \(F_1^\bigcirc\). The rules (in the bottom-up view) applied during the procedure **DERIVATION** never destroy, merge or split overgroups and every given overgroup, together with its label (as well as the status of being or not being the master overgroup) is automatically inherited without changes in all subsequent/new cirquents. So, when \(O\) is an overgroup of a given cirquent, we will terminologically treat the corresponding — inherited from \(O\) in an obvious sense of “inheritance” hardly requiring any formal explanation — overgroup of a subsequent cirquent as “the same overgroup”, and refer to the latter using the same name \(O\). Similarly in the case of undergroups or oformulas whenever the corresponding inheritance is obvious.

**DERIVATION** proceeds by consecutively performing the following **stages** 1 through 4 over and over again until none of the four stages results in any changes to the “current cirquent” \(C\). Every stage will involve zero or more **steps**, with each step changing the value of \(C\) to that of one of its legitimate premises through applying (bottom-up) one of the rules of **CL15**. The images of the oformulas not affected/modified by a given application of a rule (by a given step) are implicitly assumed to remain unchanged when moving from conclusion to premise.

**Stage 1.** Keep applying to \(C\) Conjunction Introduction and Disjunction Introduction as long as possible. As a result, we end up with a cirquent that has no oformulas (this does not extend to osubformulas of oformulas though!) of the form \(E \land G\) or \(E \lor G\). Whenever \(\lor \{\alpha, \beta\}\) was the image of an oformula \(E \land G\) (see Condition [10.3(ii)]) of the cirquent and \(E \land G\) was split into \(E\) and \(G\) as a result of applying Conjunction Introduction, the image of \(E\) in the new cirquent is stipulated to be \(\alpha\) and the image of \(G\) is stipulated to be \(\beta\). Similarly, whenever \(\lor \{\alpha, \beta\}\) was the image of an oformula \(E \lor G\) (see Condition [10.3(iii)]) of the cirquent and \(E \lor G\) was split into \(E\) and \(G\) as a result of applying Disjunction Introduction, the image of \(E\) in the new cirquent is \(\alpha\) and the image of \(G\) is \(\beta\).

**Stage 2.** Assume \(\check{E}\) is an oformula of \(C\), and \(\land \{\alpha\}\) is its image (see Condition [10.3(iv)]). Turn \(\check{E}\) into \(E\) using Recurrence Introduction. The newly emerged overgroup gets labeled with the unital origin

---

13And hence we will not bother to explicitly verify it.

14Even if those rules may modify the order, quantity or contents of overgroups.
of $\land\{\alpha\}$, and the image of the newly emerged oformula $E$ becomes $\alpha$. Repeat such a step as long as possible.

Stage 3. Assume $\circ E$ is an (unchecked) oformula of $C$, and $\vee\{\alpha_1, \ldots, \alpha_n\}$ is its image (see Condition 10.3(v)). Using Contraction $n - 1$ times, generate $n$ copies of $\circ E$. For each $i$ with $1 \leq i \leq n$, the image of the $i$'th copy of $\circ E$ will be $\alpha_i$. Repeat such a step as long as possible.

Stage 4. Assume $\circ E$ is a (checked) oformula of $C$, and $\alpha$ is its image. Further assume that, for every subhyperformula $\beta$ of $F_4$, whenever ORG($\beta$) dominates ORG($\alpha$) in $F_4^T$, ORG($\beta$) is the label of one of the overgroups of $C$. Then, using Corecurrence Introduction, turn $\circ E$ into $E$, and include $E$ in addition to the old overgroups already containing $(\circ E)$ in exactly those overgroups that are labeled by some unit $\circ H$ such that $\circ H$ dominates ORG($\alpha$) in $F_4^T$. The image of $E$ is stipulated to remain $\alpha$. Repeat such a step as long as possible.

Lemma 10.4 Assume $C$ is the “current cirquent” at a given step of applying DERIVATION, and $E$ is an unchecked oformula of $C$. Then, with “overgroup” meaning one of $C$ and “dominates” meaning “dominates in $F_4^T$”, we have:

(a) $E$ is in the master overgroup.
(b) Whenever $E$ is in some non-master overgroup $O$, the label of $O$ dominates ORG(Img$^C(E)$).
(c) Whenever $\alpha$ is a subhyperformula of $F_4$ and ORG($\alpha$) dominates ORG(Img$^C(E)$), there is an ORG($\alpha$)-labeled overgroup $O$ such that $E$ is in $O$.

\textbf{Proof.} Assume the conditions of the lemma.

Clause (a): At the very beginning of the work of DERIVATION, the oformula $F_0$ is included in the master overgroup. This inclusion is automatically inherited by all later-emerged oformulas of all later-emerged cirquents.

Clause (b): Assume $O$ is a non-master overgroup of $C$ containing $E$. $C$ cannot be the initial cirquent $F_4\bowtie$, because the only overgroup of the latter is the master overgroup. Let $C'$ be the cirquent immediately preceding $C$ (immediately below $C$) in the bottom-up derivation constructed by DERIVATION.

If the transition from $C'$ (the conclusion) to $C$ (the premise) did not modify $E$, then it is clear that $O$ already existed in $C'$ and contained $E$. Further, the image of $E$ in $C$ is the same as in $C'$. Also, as always, the label of $O$ in $C$ is the same as in $C'$. By the induction hypothesis\footnote{If here $n = 1$, no rule is applied, and simply $\circ E$ is replaced by $\circ E$.}, the label of $O$ dominates ORG(Img$^C(E)$), and thus dominates ORG(Img$^C(E)$).

Now assume the transition from $C'$ to $C$ modified $E$.

One possibility is that $C'$ contained $E \lor G$ (or $G \lor E$, or $E \lor G$, or $G \land E$, but these cases are similar) and $E$ emerged in $C$ during Stage 1 as a result of splitting this oformula into its two components $E$ and $G$. Note that $O$ already existed in $C'$ and contained $E \lor G$. So, by the induction hypothesis, the label of $O$ dominates ORG(Img$^C(E \lor G)$). But ORG(Img$^C(E)$) is a subunit of ORG(Img$^C(E \lor G)$). Hence, by Lemma 8.3 the label of $O$ also dominates ORG(Img$^C(E)$).

Another possibility is that $C'$ contained $\circ E$, and $E$ emerged in $C$ during Stage 2 as a result of deleting the prefix $\bowtie$. If $C'$ already contained $O$, the case is similar to the previous one. Otherwise, the label of $O$ is nothing but ORG(Img$^C(\bowtie E)$). But ORG(Img$^C(E)$) is a proper subunit of the latter and, by the definition of domination, is dominated by it.

The final possibility is that $C'$ contained $\circ E$, and $E$ emerged in $C$ during Stage 4 as a result of deleting the prefix $\circ$. Note that $O$ already existed in $C'$. If $O$ contained $\circ E$ in $C'$, then, by the induction hypothesis, the label of $O$ dominates ORG(Img$^C(\circ E)$). But Img$^C(\circ E) = Img^C(E)$. Thus, the label of $O$ dominates ORG(Img$^C(E)$). And if $O$ did not contain $\circ E$ in $C'$, then the label of $O$ dominates ORG(Img$^C(E)$), because otherwise $E$ would not have been included in $O$ when transferring from $C'$ to $C$ according to the prescriptions of Stage 4.

Clause (c): Assume $\alpha$ is a subhyperformula of $F_4$ and ORG($\alpha$) dominates ORG(Img$^C(E)$). In the initial cirquent $F_4\bowtie$, the only oformula is $F_0$ and the unital origin of its image is the root of $F_4^T$. By clause (i) of Lemma 8.3.1 the latter is not dominated by anything. So, $C$ cannot be the initial cirquent $F_4\bowtie$. Let $C'$ be the cirquent immediately preceding $C$ in the derivation constructed by DERIVATION.

\footnote{Where induction is on the number of the steps of DERIVATION preceding the step at which $C$ was generated.}
If the transition from $C'$ (the conclusion) to $C$ (the premise) did not modify $E$, then, by the induction hypothesis, $C'$ already had an $\text{Org}(\alpha)$-labeled overgroup $O$ such that $O$ contained $E$. This situation is then automatically inherited by $C$ from $C'$.

Now assume the transition from $C'$ to $C$ modified $E$.

One possibility is that $C'$ contained $E \lor G$ or $G \lor E$, or $E \land G$, or $G \land E$, but these cases are similar, and $E$ emerged in $C$ during Stage 1 as a result of splitting this oformula into its two components $E$ and $G$. In view of clause (a) of Lemma 8.3, $\text{Org}(\alpha)$ dominates $\text{Org}(\text{Img}^{C'}(E \lor G))$. Hence, by the induction hypothesis, an $\text{Org}(\alpha)$-labeled overgroup $O$ existed in $C'$ and it included $E \lor G$. The same overgroup and the corresponding inclusion are inherited by $C$ and its oformula $E$.

Another possibility is that $C'$ contained $\downarrow E$, and $E$ emerged in $C$ during Stage 2 as a result of deleting the prefix $\downarrow$. In view of clause (b) of Lemma 8.3, $\text{Org}(\alpha)$ is either the same as $\text{Org}(\text{Img}^{C'}(\downarrow E))$ or dominates $\text{Org}(\text{Img}^{C'}(\downarrow E))$. In the former case, the new overgroup emerged during the transition from $C'$ to $C$ is $\text{Org}(\alpha)$-labeled and it includes $E$. In the latter case, by the induction hypothesis, an $\text{Org}(\alpha)$-labeled overgroup $O$ existed in $C'$ and it included $\downarrow E$. The same overgroup and the corresponding inclusion are inherited by $C$ and its oformula $E$.

The final possibility is that $C'$ contained $\sqrt[4]{E}$, and $E$ emerged in $C$ during Stage 4 as a result of deleting the prefix $\sqrt[4]{.}$ But in this case the conditions of Step 4 immediately guarantee that clause (c) of the present lemma is satisfied. ■

**Lemma 10.5** Assume $C$ is the “current cirquent” at some given step of applying DERIVATION, $L$ and $M$ are literals that happen to be oformulas of $C$, and the unital origins of their $C$-images are opposite. Then $L$ and $M$ are opposite (one is the negation of the other), and they are contained in exactly the same overgroups of $C$.

**Proof.** Assume the conditions of the lemma. Below, “dominates” should be understood as $11$dominates in $\mathbb{F}_T$. That $L$ and $M$ are opposite is immediate from Condition 10.3. Next, Lemma 8.4 implies that $\text{Org}(\text{Img}^{C}(L))$ and $\text{Org}(\text{Img}^{C}(M))$ are dominated by exactly the same $\downarrow$-units of $\mathbb{F}_T$. Let $S$ be the set of all $\downarrow$-units of $\mathbb{F}_T$ that dominate $\text{Org}(\text{Img}^{C}(L))$ (and/or $\text{Org}(\text{Img}^{C}(M))$) and that also happen to be the unital origins of some subhyperformulas of $F_4$. Further, let $S'$ be the (sub)set of overgroups of $C$ consisting of the master overgroup and those overgroups whose labels are in $S$. Then, according to Lemma 10.4, $S'$ is exactly the set of the overgroups of $C$ in which $L$ is contained, and the same holds for $M$. ■

What we below call a **hypercirquent** is defined in exactly the same way as a cirquent, with the only difference that while cirquents are formula-based, hypercirquents are hyperformula-based. Correspondingly, “**ohyperformula**” in the context of hypercirquents means the same as “oformula” in the context of cirquents.

We say that a hypercirquent $D$ is **binary** iff so are all of its ohyperformulas and, in addition, for every hyperatom $\alpha$, there is at most one ohyperformula in $D$ in which $\alpha$ has a positive occurrence, and at most one ohyperformula in $D$ in which $\alpha$ has a negative occurrence. Next, we say that $D$ is **tautological** iff, for every undergroup $U$ of $D$, the disjunction of all ohyperformulas of $U$ is a tautology. Finally, we say that $D$ is a **binary tautology** iff it is both binary and tautological.

We agree that, whenever $C$ is a cirquent generated by DERIVATION, the **image** of $C$, denoted by $\text{Img}(C)$, means the hypercirquent resulting from $C$ through replacing each oformula $E$ by $\text{Img}^{C}(E)$, otherwise retaining all arcs, groups and group labels.

The following two lemmas can be verified by a routine induction on the number of cirquents generated by DERIVATION earlier than $C$, in the same style as in the proof of Lemma 10.4. Hence we state them.

---

17Note that being an oformula of $C$ means being strictly “on the surface” of $C$. Namely, proper osubformulas of oformulas of $C$ do not count as oformulas of $C$.

18In the case of Lemma 10.6 the basis of induction will be provided by that already observed fact that $\mathbb{F}_4$ is a binary tautology.
Lemma 10.6 Assume $C$ is the “current cirquent” at some given step of applying Derivation. Then $\text{IMG}(C)$ is a binary tautology.

Lemma 10.7 Assume $C$ is the “current cirquent” at some given step of applying Derivation, and $\alpha H$ is the unital origin of some subhyperformula $\alpha$ of $\mathcal{F}_4$. Then either $\alpha$ is a subhyperformula of some ohyperformula of $\text{IMG}(C)$, or there is a $\alpha H$-labeled overgroup in $C$.

In what follows, $\mathbb{D}$ stands for the final cirquent produced by the procedure Derivation. Since Derivation always moves from a conclusion to a legitimate premise, we have:

$F_0^\Lambda$ is derivable in CL15 from $\mathbb{D}$.  \hfill (39)

Lemma 10.8 Every oformula of $\mathbb{D}$ is a literal, and hence every ohyperformula of $\text{IMG}(\mathbb{D})$ is a hyperliteral.

Proof. Note that, if every oformula of $\mathbb{D}$ is a literal, then, in view of Condition 10.3(i), every ohyperformula of $\text{IMG}(\mathbb{D})$ is indeed a hyperliteral. So, we only need to verify that all oformulas of $\mathbb{D}$ are literals. For a contradiction, deny this. Throughout this proof, domination means domination in $F_4$.

$\mathbb{D}$ cannot have an oformula of the form $E \lor F$ or $E \land F$, because the corresponding Disjunction Introduction or Conjunction Introduction is always applicable, and thus such a formula would have been split into $E$ and $F$ during Stage 1 of Derivation. Next, there can be no oformulas of the form $\alpha F$ in $\mathbb{D}$ either, as Stage 2 would immediately apply Recurrence Introduction and turn it into $F$. Similarly, $\mathbb{D}$ cannot have oformulas of the form $\alpha F$, because such oformulas would have been modified during Stage 3.

So, $\mathbb{D}$ must have some oformulas of the form $\alpha F$. Let $S$ be the set of all hyperformulas $\gamma$ such that $\gamma$ is a subhyperformula of some ohyperformulas of $\text{IMG}(\mathbb{D})$ and $\text{ORG}(\gamma)$ is a $\bot$-unit. In view of Lemma 10.7, $S$ can be seen to be nonempty, for otherwise all oformulas of the form $\alpha F$ would have been eliminated during Stage 4 of Derivation. Next, in view of clauses (ii) and (iii) of Lemma 9.1 (namely, the transitive and asymmetric — and hence irreflexive — properties of the relation of domination), it is easy to see that there is an element $\alpha$ of $S$ whose unital origin is not dominated by the unital origins of any other elements of $S$. Such an $\alpha$ obviously should be a subhyperformula of $\text{IMG}(\mathcal{D})(\alpha E)$ for some oformula $\alpha E$ of $\mathbb{D}$ (because there are no $\lor$, $\land$- or $\alpha$-oformulas in $\mathbb{D}$). Note that $\text{ORG}(\alpha)$ is a subunit of $\text{ORG}(\text{IMG}(\mathcal{D})(\alpha E))$. But then, in view of clause (ii) of Lemma 9.1, $\text{ORG}(\text{IMG}(\mathcal{D})(\alpha E))$ is not dominated by $\text{ORG}(\alpha)$. Nor is it dominated by the unital origin of any other element of $S$, because then, by Lemma 8.3, so would be $\text{ORG}(\alpha)$. With Lemma 10.7 in mind, the observation we have just made means that, for every subhyperformula $\beta$ of $\mathcal{F}_4$, whenever $\text{ORG}(\beta)$ dominates $\text{ORG}(\text{IMG}(\alpha E))$, $\text{ORG}(\beta)$ is the label of one of the overgroups of $\mathbb{D}$. But, if so, $\alpha E$ cannot be an oformula of $\mathbb{D}$, because Stage 4 of Derivation would have turned it into $E$. This is a contradiction. $\blacksquare$

Lemma 10.9 CL15 $\vdash \mathbb{D}$.

Proof. For any atom $P$, whenever $P$ (resp. $\neg P$) is an oformula of $\mathbb{D}$ and $\alpha$ is a hyperatom with $\alpha = \text{IMG}(\mathcal{D})(P)$ (resp. $\neg \alpha = \text{IMG}(\mathcal{D})(\neg P)$), we call the atom $P$ the preimage of $\alpha$. In view of Condition 10.3(i), the concept of preimage is well defined on the atoms found in $\mathbb{D}$: every hyperatom occurring in (some ohyperformula of) $\text{IMG}(\mathbb{D})$ has a unique preimage. Now note that $\mathbb{D}$ is a substitutional instance of $\text{IMG}(\mathbb{D})$, in the sense that $\mathbb{D}$ is the result of replacing in $\text{IMG}(\mathbb{D})$ every (occurrence of every) hyperatom $\alpha$ by the preimage of $\alpha$.

For our present purposes, we ignore the irrelevant technicality that $\text{IMG}(\mathbb{D})$ is a hypercircuient rather than a cirquent, and treat it as an ordinary cirquent to which the ordinary rules of CL15 can be
In what follows, we show that \( \text{CL15} \vdash \text{IMG(D)} \). In view of Condition \ref{10.3} this immediately implies that \( \text{CL15} \vdash D \), because any \( \text{CL15} \)-proof \( T \) of \( \text{IMG(D)} \) automatically turns into a \( \text{CL15} \)-proof of \( D \) once, in all cirquents of \( T \), we replace every occurrence of every hyperatom by the preimage of that atom.

We agree that, in our description of a \( \text{CL15} \)-proof of \( \text{IMG(D)} \), \( C \) always stands for the “current hypercirquent”. Also, in what follows, we do not explicitly mention Exchange even though the latter may have to be occasionally used to make applications of the other rules possible.

According to Lemma \ref{10.9}, \( \text{IMG(D)} \) is a (binary) tautology. In view of Lemma \ref{10.8} the tautologicity of \( \text{IMG(D)} \) obviously implies that every undergroup of \( \text{IMG(D)} \) contains a pair of opposite hyperliterals. We choose one such pair for each undergroup of \( \text{IMG(D)} \). Then, starting from \( C = \text{IMG(D)} \) and moving in the “from conclusion to premise” direction, we apply a series of Weakenings to \( C \) and delete from each undergroup all ohyperformulas except the chosen pair.

Thus, now every undergroup \( U \) of (the resulting value of) \( C \) has exactly two ohyperformulas \( \alpha \) and \( \neg \alpha \), where \( \alpha \) is an atom. It is obvious that \( C \) remains a binary tautology. The binity of \( C \), in turn, implies that, whenever two undergroups \( U_1 \) and \( U_2 \) share an ohyperformula, they share both ohyperformulas — that is, \( U_1 \) and \( U_2 \) have identical contents. As our next step, using a series of Undergroup Duplications, from each set of identical-content undergroups, we eliminate all but one undergroup. Now, no two undergroups share ohyperformulas, and every undergroup \( U \) (as before) contains exactly two ohyperformulas \( \alpha_U \) and \( \neg \alpha_U \), where \( \alpha_U \) is a hyperatom. Note also that, in view of Lemma \ref{10.5}, every such pair \( \alpha_U, \neg \alpha_U \) of ohyperformulas is included in exactly the same overgroups.

The content of every overgroup \( O \) of the resulting cirquent \( C \) is \( \{ \alpha_{U_1}, \neg \alpha_{U_1}, \ldots, \alpha_{U_n}, \neg \alpha_{U_n} \} \) for some undergroups \( U_1, \ldots, U_n \). Now, applying a series of Mergings, we split every such overgroup \( O \) into \( n \) overgroups, whose contents are \( \{ \alpha_{U_1}, \neg \alpha_{U_1} \}, \ldots, \{ \alpha_{U_n}, \neg \alpha_{U_n} \} \). Finally, using a series of Overgroup Duplications, from each set of identical-content overgroups, we eliminate all but one overgroup. This way we end up with an axiom.

As an immediate corollary of \( \ref{39} \) and Lemma \ref{10.9} we find that \( \text{CL15} \vdash F_0^* \). Claim \( \ref{38} \) is thus proven, and so is Lemma \ref{10.2}.

### 11 Uniform completeness

In the following lemma, \( H \) and \( e \) are the HPM and the valuation fixed in Section \ref{5}.

**Lemma 11.1** There is a constant enumeration interpretation * such that \( H \) does not win \( F_0^* \). Namely, \( H \) loses this game against \( E \) on \( e \).

**Proof.** According to Lemma \ref{10.2} \( \overline{F_1} \) is not tautological. This means there is a hypermodel \( h \) such that \( h \) makes \( F_1 \) false. We now define the interpretation * by stipulating that, for every atom \( P \), \( P^* \) is the constant enumeration game such that, for any legal run \( \Gamma \) of \( P^* \), \( \text{Wn} P^* (\Gamma) = \top \) iff \( h \) makes the hyperliteral \( (P, A, B) \) true, where \( A \) and \( B \) are the following sets of natural numbers:

\[
A = \{ a \mid \Gamma \text{ contains the labmove } \top a \}; \\
B = \{ b \mid \Gamma \text{ contains the labmove } \bot b \}.
\]

It is not hard to see that \( \Omega \) — the \( H \) vs. \( E \)-run on \( e \) fixed in Section \ref{5} — is a \( \bot \)-won run of \( F_0^* \). Thus, \( H \) loses \( F_0^* \) against \( E \) on \( e \). ■

Now, remembering that \( F_0 \) was an arbitrary (even if fixed) \( \text{CL15} \)-unprovable formula, Lemma \ref{11.4} means nothing but that the implication \( (ii) \Rightarrow (i) \) (that is, \( \neg (i) \Rightarrow \neg (ii) \)) of Theorem 6 of \[11\], in the strong form of clause (b) of that theorem, holds.

\(^{19}\)Of course, the rules of Contraction, Recurrence Introduction and Corecurrence Introduction automatically become redundant/inapplicable, because hyperformulas cannot contain \( \delta \) or \( \nabla \).
**Remark 11.2** For good reasons (see, for instance, the end of Section 9 of [10]), CoL takes no interest in non-effective strategies. It would however be a pity to leave it unobserved that we have never really relied on the fact that the strategy of $E$’s adversary was algorithmic. Namely, our entire argument and Lemma 11.1 in particular would just as well go through if $H$ was an HPM with an arbitrary oracle, and hence its strategy was not-necessarily-effective. Thus, whenever CL15 does not prove a formula $F$, there is simply no strategy — whether effective or not — that wins $F^*$ for every constant (and enumeration) interpretation $^*$; in other words, $F$ has no uniform solution even if we do not require that uniform solutions be effective.

## 12 Multiform completeness

A transition from completeness with respect to uniform validity (“uniform completeness”) to completeness with respect to multiform validity (“multiform completeness”) is already rather standard in the literature on CoL. The diagonalization-style idea that we are going to employ below has been used in [2, 3, 4, 5, 6, 7, 8, 9] for a number of other deductive systems for CoL in multiform completeness proofs.

Let
\[ H_0, H_1, H_2, \ldots \] (40)
be a fixed list of all HPMs (say, arranged in the lexicographic order of their descriptions).

Next, we pick a variable $x$, and let
\[ e_0, e_1, e_2, \ldots \] (41)
be the valuations such that, for each $n \geq 0$, $e_n$ assigns $n$ to $x$ and assigns 0 to all other variables.

Remember that, even though $H$ and $e$ have been fixed so far, they were an arbitrary HPM and an arbitrary valuation. This means that $H$ and $e$ just as well could have been treated — as we are going to do from now on — as a variable ranging over HPMs and a variable ranging over valuations, respectively. Everything we have proven about the fixed $H$ and $e$ automatically goes through for $H$ and $e$ as variables. Namely, considering only (HPM,valuation) pairs of the form $(H_n, e_n)$, Lemma 11.1 can now be re-written as follows:

**Lemma 12.1** For every natural number $n$ there is a constant enumeration interpretation $^*n$ — which we choose and fix for the purposes of this section — such that the HPM $H_n$ from the list (40) does not win the game $F_n^*$ against our EPM $E$ on the valuation $e_n$ from the list (41).

We now define an enumeration interpretation $\uparrow$ such that $P^\uparrow$ (any atom $P$) is a unary game that depends on no variables other than $x$. Namely, we let $P^\uparrow$ be the game such that, for any valuation $e$, $e[P^\uparrow] = P^*\uparrow$, where $n$ is the value assigned to the variable $x$ by $e$, and $^*n$ is the interpretation fixed in Lemma 12.1 for $n$. Of course, $\uparrow$ is a unary interpretation, as promised in clause (c) of Theorem 6 of [11]. To complete our proof of that clause, we need to show that no HPM wins $F_0^*$.

But indeed, consider an arbitrary HPM $H$. Since all HPMs are on the list (40), we have $H = H_n$ for some $n$ (fix the latter). Next, consider the valuation $e_n$ from the list (41). By our choice of $\uparrow$, for every atom $P$ we have $e_n[P^\uparrow] = P^{*n}$. Clearly this extends from atoms to compound formulas as well, so $e_n[F_0^\uparrow] = F_0^{*n}$. By Lemma 12.1 $H_n$ — i.e. $H$ — does not win $F_0^{*n}$ against $E$ on $e_n$. Thus, $H$ does not win $e_n[F_0^\uparrow]$ against $E$ on $e_n$. But not winning $e_n[F_0^\uparrow]$ against $E$ on $e_n$ obviously means the same as not winning $F_0^*$ against $E$ on $e_n$. Thus, $H$ does not win $F_0^*$, as desired.
