Abstract

We study transport properties of Schrödinger operators depending on one or more parameters. Examples include the kicked rotor and operators with quasi-periodic potentials. We show that the mean growth exponent of the kinetic energy in the kicked rotor and of the mean square displacement in quasi-periodic potentials is generically equal to 2: this means that the motion remains ballistic, at least in a weak sense, even away from the resonances of the models. Stronger results are obtained for a class of tight-binding Hamiltonians with an electric field \( E(t) = E_0 + E_1 \cos \omega t \). For

\[
H = \sum a_{n-k} (| n - k > < n | + | n > < n - k |) + E(t) | n > < n |
\]

with \( a_n \sim n^{-\nu} \) (\( \nu > 3/2 \)) we show that the mean square displacement satisfies \( < \psi_t, N^2 \psi_t > \geq C_\epsilon t^{2/((\nu+1/2)-\epsilon)} \) for suitable choices of \( \omega, E_0 \) and \( E_1 \). We relate this behaviour to the spectral properties of the Floquet operator of the problem.

1 Introduction and statement of the results

The asymptotic behaviour of time dependent quantities in the study of Schrödinger equations with quasi-periodic and random potentials, or in the study of periodically kicked or pulsed Hamiltonian systems has attracted much attention in the last decade. For a review we refer to [Ho] where many references beyond the ones cited below can be found. We present in section 2 two simple abstract results stating roughly that “close to resonance” the spectrum of the Hamiltonian or the Floquet operator is continuous and that the motion has the same asymptotic characteristics as “in resonance”, at least in some weak sense. In section 3, we first apply these results to the kicked rotor. We give a simplified proof of the Casati-Guarnieri result stating that generically the spectrum of the Floquet operator of the kicked rotor is continuous. We show in addition that the mean growth exponent of the time-averaged kinetic energy, defined below, generically equals 2 (Theorem 3.1). This can be paraphrased (somewhat exaggeratedly) by saying that the time-averaged kinetic energy generically behaves ballistically in the kicked rotor. We then show how to prove similar results for quasi-periodic Schrödinger operators. In section 4, we study in detail the asymptotic behaviour of the kicked linear rotor. We exhibit various phenomena relating the asymptotic behaviour of the time-averaged kinetic energy and the nature of the spectrum of the Floquet operator, strengthening known results. In section 5 we then show how these results apply to the problem of the motion of a charged particle in a one-band tight-binding model subjected to a time-dependent electric field (Theorem 5.1). We now first describe our results and the motivations in some more detail.

Consider a periodically driven classical or quantal Hamiltonian system with Hamiltonian

\[ H(t) = H_0 + V(t), \quad V(t + T) = V(t). \]

In classical mechanics the evolution of the system is determined by the Floquet transformation \( \Phi_V \), obtained by integrating the Hamiltonian equations of motion over one period \( T \). It is a canonical transformation of phase space \( M \). Similarly, in quantum mechanics, integration of the Schrödinger equation over one period \( T \) yields the Floquet operator \( U_V \), which is a unitary operator on the Hilbert space of states \( \mathcal{H} \). Typically, the unperturbed classical Hamiltonian is chosen to be completely integrable with its motion restricted to invariant tori, so that in particular all its trajectories are bounded. The
corresponding quantum Hamiltonian is assumed to have pure point spectrum so that the same is true for \( U_0 = \exp -\frac{i}{\hbar}TH_0 \). What happens when \( V \) is turned on?

A natural first question to ask is whether the unperturbed energy \( H_0 \), which is a constant of the motion when \( V = 0 \), remains bounded when \( V \neq 0 \). More precisely, the question in classical mechanics is whether

\[
\sup_{m \in \mathbb{Z}} | H_0 \circ \Phi^m_V(x, p) | < \infty, \ (x, p) \in M,
\]

and in quantum mechanics whether

\[
\sup_{m \in \mathbb{Z}} | <\psi, U^{-m}_V H_0 U^m_V \psi > | < \infty, \psi \in \mathcal{D}(H_0),
\]

where \( \mathcal{D}(H_0) \) denotes the domain of \( H_0 \), assumed stable under \( U_V \). Without giving a precise definition, let us say the system is dynamically stable in this case, and dynamically unstable otherwise.

In quantum mechanics one can ask a different, but related stability question \[Be\][Ho]: is the spectrum of the Floquet operator \( U_V \) still pure point? We will say the system is spectrally stable if this is the case. It is a well known consequence of the RAGE theorem \[CFKS\] that dynamical stability implies spectral stability, the opposite implication not being true \[DJLS\].

We will be interested in dynamically unstable systems. Once the unperturbed energy does not remain bounded under the full, perturbed evolution, one can ask about its asymptotic behaviour: how do \( | H_0 \circ \Phi^m_V(x, p) | \) and \( | <\psi, U^{-m}_V H_0 U^m_V \psi > | \) behave as \( m \) goes to infinity? One is in particular interested in finding out whether these quantities can have algebraic growth and, in the quantum mechanical case, to relate the growth exponent to the spectral properties of \( U_V \).

Before reviewing the known results, let us quickly recall the various notions of growth exponent one might consider. Let \( h_m \) be a sequence of positive numbers. One says the sequence displays algebraic growth with exponent \( \alpha(h) \geq 0 \) if there exist constants \( c \) and \( C \) so that, for all \( m \in \mathbb{N}^* \)

\[
c m^{\alpha(h)} \leq h_m \leq C m^{\alpha(h)}.
\]

It turns out this notion is too strong to be of use: the quantities of interest tend to fluctuate greatly as we will show in detail for the kicked linear rotor in section 4. To obtain a fluctuation independent quantity, it has been
suggested [Gu] one should consider a “mean growth exponent” $\alpha_0(h)$ defined as

$$\alpha_0(h) = \inf \{ \alpha > 0 \mid \sum_{m=1}^{\infty} \frac{1}{m^{1+\alpha}} h_m < \infty \}$$

$$= \sup \{ \alpha > 0 \mid \sum_{m=1}^{\infty} \frac{1}{m^{1+\alpha}} h_m = \infty \} , \quad (1.2)$$

where we use the (unusual) convention that $\inf \emptyset = \infty$ and $\sup \emptyset = 0$. One could alternatively decide to take the fluctuations into account, and introduce upper and lower growth exponents in the obvious way [Gu]:

$$\alpha^+(h) = \limsup_{m \to \infty} \frac{\log h_m}{\log m}, \quad \alpha^-(h) = \liminf_{m \to \infty} \frac{\log h_m}{\log m} . \quad (1.3)$$

Note that, even if $\alpha^+(h) = \alpha^-(h)$, (1.1) does not necessarily hold. On the other hand,

$$\alpha^-(h) \leq \alpha_0(h) \leq \alpha^+(h) .$$

In addition, if (1.1) holds, $\alpha(h) = \alpha^+(h) = \alpha^-(h) = \alpha_0(h)$.

Let us write

$$< \psi, U_V^{-m} H_0 U_V^m \psi > = \frac{1}{m} \sum_{k=1}^{m} < \psi, U_V^{-k} H_0 U_V^k \psi > .$$

The problem is to get upper and lower bounds on this quantity. Upper bounds of the type

$$< \psi, U_V^{-m} H_0 U_V^m \psi > \leq C m^\alpha \quad (1.4)$$

were obtained in [N] under the assumption that $V(t)$ is smooth and the spectrum of $H_0$ satisfies a gap condition at infinity (see also [J]). The proofs are based on adiabatic techniques that do not allow for non-smooth time dependence and therefore do not apply to kicked systems. In addition, they do not provide lower bounds. One might hope to obtain lower bounds from an abstract approach initiated in [Gu] and perfected in [C] [L] [BCM].

Writing

$$U_V = \int \exp i \lambda \ dE_\lambda$$

for the spectral decomposition of $U_V$, the main result of this theory (Theorem 6.1 in [L], Theorem 3 in [BCM]) states the following. If the spectral measure $d < \psi, E_\lambda \psi > \equiv d\mu_\psi(\lambda)$ has Hausdorff dimension $\beta$ for some
0 ≤ β ≤ 1 then there exists for all ε > 0 a constant C_{\epsilon}, so that, for all \( m \in \mathbb{N}^* \),
\[
< \psi, U^{-m}_V H_0 U^m_V \psi > \geq C_{\epsilon} m^{\gamma_{H_0}(\beta-\epsilon)}.
\tag{1.5}
\]
Here the constant \( \gamma_{H_0} \) depends on the spectral properties of \( H_0 \) in an explicit way [Gu]. The trouble with such lower bounds is that the information on the spectral measure is very hard to check: we do not know of any models where this has been done (other than numerically or for the trivial case where \( \beta = 0 \) or 1). As a result, we are not aware of any models where lower bounds of the type (1.5) (i.e. for all \( m \)) have been proven to hold for \( U_V \) with singular spectrum (other than numerically: see [Gu] for references).
We will give such a model in sections 4-5.

Actually, the only lower bound we know off is a result of Last ([L], Theorem 7.2) who shows that in the Almost Mathieu equation there exist Liouville frequencies so that the quantity \( < \psi_t, X^2 \psi_t > \) (with \( \psi_0 = \delta_0 \)) has an upper growth exponent \( \alpha_+ = 2 \). We will strengthen this result in the following sense. We will show in sections 3 that, not only in the Almost Mathieu equation (Theorem 3.2), but more generally in Schrödinger operators with quasi-periodic potentials as well as in the kicked rotor the relevant dynamical quantity has generically a mean growth exponent \( \alpha_0 = 2 \). The proof turns out to be very simple and is based on standard Baire theoretical arguments, sometimes irreverentially referred to as generic nonsense (section 2). It seems therefore that the occurrence of ballistic peaks close to resonance is a rather common phenomenon.

The growth exponents \( \alpha_+ \) and \( \alpha_0 \) only give lower bounds along a sub-sequence of times. To display a model in which non-trivial lower bounds at all times can be obtained, we present in section 5 a tight-binding Hamiltonian with electric field \( E(t) = E_0 + E_1 \cos \omega t \) and show that, for suitable choices of \( \omega, E_1 > E_0 \) and provided the off-diagonal matrix elements satisfy \( a_n \sim |n|^{-\nu} (\nu > 3/2) \), one has for all \( \ell \) and \( m \)
\[
< \delta_\ell, U_T^{-m} N^2 U_T^m \delta_\ell > \geq C_{\epsilon} m^{\nu+3/2-\frac{\nu}{2}-\epsilon},
\]
where \( U_T \) is the Floquet operator of the theory (Theorem 5.1). This result is obtained by remarking that the model is equivalent to a kicked linear rotor and upon using results of [DBF]. A detailed analysis of the spectral properties of \( U_T \) is also given.
2 Two generic results

In many situations of interest either the Hamiltonian $H(\omega)$ or the Floquet operator $U(\omega)$ depend on one or several real variables in such a way that for a dense set of values of $\omega$ a “resonance” occurs. We will give examples in the next sections. For these values the spectrum is absolutely continuous and much is then known about the dynamical behaviour of the system. We show in this section two abstract results permitting to use this information to draw conclusions on the nature of the spectrum and on the asymptotic dynamical behaviour of the system for generic values of $\omega$, “off resonance”.

The term generic is used here in the topological sense. It means for $\omega$ belonging to a dense $G_\delta$-set. We recall that a $G_\delta$ set is a countable intersection of open sets and that, on $\mathbb{R}^n$, an intersection of two dense $G_\delta$-sets is still a dense $G_\delta$-set. In addition, dense $G_\delta$-sets are locally uncountable. It should nevertheless be stressed that dense $G_\delta$-sets can very well be of zero measure; in fact, in many applications where the set can be described explicitly, this is the case.

Let $\mathcal{H}$ be a Hilbert space and $A$ a self-adjoint operator on $\mathcal{H}$ with domain $\mathcal{D}(A)$. Let $H(\omega)$ be a family of self-adjoint operators on $\mathcal{H}$ with common domain $\mathcal{D}$: we will assume throughout it is continuous in the strong resolvent sense. We will write $U_t(\omega) = \exp(-itH(\omega))$ for the corresponding unitary one-parameter group, which is then strongly continuous, uniformly in $t$ on compacta [RSI].

**Proposition 2.1** Let $\mathcal{C} = \{\omega \mid \sigma_{pp}(H(\omega)) = \emptyset\}$. Then $\mathcal{C}$ is a $G_\delta$ set. In particular, if $\mathcal{C}$ is dense, it is a dense $G_\delta$.

In the following, we suppose

$$H(\omega) = H_0 + V_\omega,$$

where $H_0$ is self-adjoint with domain $\mathcal{D}$ and the $V_\omega$ form a strongly continuous family of bounded self-adjoint operators.

**Proposition 2.2** Suppose $\mathcal{D}(A) \cap \mathcal{D}$ is dense and

1. $\forall \omega \in \mathbb{R}^n, \forall t \in \mathbb{R}$, $U_t(\omega)\mathcal{D}(A) \subset \mathcal{D}(A)$;
2. $\forall \omega \in \mathbb{R}^n$, $[H(\omega), A]$ is relatively $H_0$ bounded and the map $\omega \in \mathbb{R}^n \to [H(\omega), A](H_0 + i)^{-1} \in \mathcal{L}(\mathcal{H})$ is strongly continuous.
Suppose in addition that for some \( \psi \in \mathcal{D}(A) \cap \mathcal{D} \) there exists a \( \beta_0 > 0 \) so that for all \( \omega \) in a dense subset \( \mathcal{R}_\psi \) of \( \mathbb{R}^n \)

\[
\beta_0 = \sup \{ \alpha > 0 \mid \int_1^\infty \frac{dt}{t^{1+\alpha}} < U_t(\omega)\psi, A^*AU_t(\omega)\psi > = \infty \}. \tag{2.2}
\]

Then for all \( \omega \) in a dense \( G_\delta \) set \( S_\psi \) one has:

\[
\beta_0 \leq \sup \{ \alpha > 0 \mid \int_1^\infty \frac{dt}{t^{1+\alpha}} < U_t(\omega)\psi, A^*AU_t(\omega)\psi > = \infty \}. \tag{2.3}
\]

Remark: (i) Proposition 2.1 is Theorem 1.1 in [Si]. We have preferred to give an independent proof based on the use of the Wiener theorem, since the same type of argument serves to show Propositions 2.2-2.4; (ii) As in [Si], \( \mathbb{R}^n \) can be replaced by a complete metric space; (iii) The time-average appearing in (2.2) and (2.3) can be omitted for the abstract argument, but often appears in applications.

**Proof of Proposition 2.1:** Let \( \psi_i, i \in \mathbb{N} \) be an orthonormal basis of \( \mathcal{H} \). Consider for each \( i \in \mathbb{N} \), \( T \in [1, \infty[ \) the continuous functions

\[
R^i_T : \omega \in \mathbb{R}^n \rightarrow \frac{1}{T} \int_0^T |< \psi_i, U_t(\omega)\psi_i >|^2 \ dt \in \mathbb{R}.
\]

Then Wiener’s theorem immediately implies that

\[
C = \bigcap_{i,n \in \mathbb{N}} \bigcup_{T \in \mathbb{N}} \{ \omega \mid R^i_T(\omega) < \frac{1}{n} \}.
\]

This proves the proposition. \( \square \)

**Proof of Proposition 2.2:** We first show that the maps

\[
\omega \in \mathbb{R}^n \rightarrow < U_t(\omega)\psi, A^*AU_t(\omega)\psi > \in \mathbb{R} \tag{2.4}
\]

are continuous for all \( \psi \in \mathcal{D}(A) \). For that purpose, compute for \( \psi \in \mathcal{D}(A) \cup \mathcal{D} \)

\[
(AU_t(\omega) - AU_t(\omega'))\psi = [A, U_t(\omega)]\psi - [A, U_t(\omega')]\psi + (U_t(\omega) - U_t(\omega')A)\psi,
\]

and

\[
[A, U_t(\omega)] = U_t(\omega)i \int_0^t ds U_{-s}(\omega)[H(\omega), A]U_s(\omega).
\]
Continuity of (2.4) now follows easily. For all \( \epsilon > 0 \) and for all \( \omega \in \mathbb{R} \), (2.2) implies

\[
\sup_T \int_1^T \frac{dt}{t^{1+\beta_0-\epsilon}} < U_t(\omega)\psi, A^*AU_t(\omega)\psi > = \infty. \tag{2.5}
\]

It is a standard corollary of the Baire category theorem ([S], Corollaire 4, p 325) that (2.5) continues to hold for all \( \omega \) in a dense \( G_\delta \) set \( S_\psi \) containing \( \mathbb{R} \) and hence

\[
\int_1^\infty \frac{dt}{t^{1+\beta_0-\epsilon}} < U_t(\omega)\psi, A^*AU_t(\omega)\psi > = \infty, \quad \forall \omega \in S_\psi. \tag{2.6}
\]

Define \( S_\psi = \cap_{n \in \mathbb{N}} S_\psi^{1/n} \). Then (2.6) implies that for all \( \omega \in S_\psi \) (2.3) holds. \( \square \)

Analogous results hold when dealing with iterates of a unitary operator \( U(\omega) \). We state the results without proofs, which are completely analogous.

**Proposition 2.3** Let \( \omega \in \mathbb{R}^n \rightarrow U(\omega) \) be a strongly continuous map. If the pure point spectrum of \( U(\omega) \) is empty on a dense set of \( \omega \), then this remains true on a dense \( G_\delta \) set.

**Proposition 2.4** Suppose

(i) \( \omega \in \mathbb{R}^n \rightarrow U(\omega) \in U(\mathcal{H}) \) is strongly continuous;

(ii) \( \forall \omega \in \mathbb{R}, \ U(\omega)\mathcal{D}(A) \subset \mathcal{D}(A) \);

(iii) \( \forall \omega \in \mathbb{R}^n, \ [U(\omega), A] \) is bounded and the map \( \omega \in \mathbb{R}^n \rightarrow [U(\omega), A] \in \mathcal{L}(\mathcal{H}) \) is strongly continuous.

Suppose in addition that for some \( \psi \in \mathcal{D}(A) \) there exists a \( \beta_0 > 0 \) so that

\[
\beta_0 = \sup \{ \alpha > 0 \mid \sum_{m=1}^{\infty} \frac{1}{m^{1+\alpha}} < U(\omega)^m\psi, A^*AU(\omega)^m\psi > = \infty \}, \tag{2.7}
\]

for all \( \omega \) in a dense subset \( \mathcal{R}_\psi \) of \( \mathbb{R}^n \). Then for all \( \omega \) in a dense \( G_\delta \) set \( S_\psi \)

\[
\beta_0 \leq \sup \{ \alpha > 0 \mid \sum_{m=1}^{\infty} \frac{1}{m^{1+\alpha}} < U(\omega)^m\psi, A^*AU(\omega)^m\psi > = \infty \} \tag{2.8}
\]
3 Applications

3.1 The kicked rotor

It is hard to get rigorous results on the dynamics or on the dynamical or spectral stability for the kicked rotor [IS]. For the quantum model, with Floquet operator

\[ U_V(\omega) = \exp(-i\omega \frac{P^2}{2}) \exp(-iV(X)) \]

acting on \( L^2(S^1) \) the only rigorous result we know of is due to Casati-Guarnieri [CGu]. In the following theorem we give both an improvement on this result and a simplified proof of it.

**Theorem 3.1** Suppose \( V \in L^2(S^1) \), \( V' \in L^\infty(S^1) \) and that \( \forall \pi \omega \in \mathbb{Q} \), the spectrum of \( U_V(\omega) \) is purely absolutely continuous. Then there exists a dense \( G_\delta \) subset \( S \) of \( \mathbb{R} \) so that

(i) \( \forall \omega \in S, \sigma_{pp}(U_V(\omega)) = \emptyset \);

(ii) \( \forall \omega \in S, \) for all momentum eigenstates \( \psi_\ell(x) = \exp(i2\pi\ell x), \ell \in \mathbb{Z} \),

\[ \sup\{ \alpha > 0 | \sum_{m=1}^{\infty} \frac{1}{m^{1+\alpha}} \langle \psi_\ell, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi_\ell \rangle = \infty \} = 2, \] \( (3.9) \)

i.e. the mean growth exponent of the time-averaged kinetic energy is 2.

The proof of this result is given below. Let us first point out that the hypothesis on \( \sigma(U_V(\omega)) \) for \( \pi \omega \in \mathbb{Q} \) is proven to hold for a generic set of \( V \) in [CG]. Note that part (i) of Theorem 3.1 is Theorem 2 of [CGu]. Actually, the statement of Theorem 2 in [CGu] is weaker than the one given here, but Theorem 3.1(i) immediately follows from their proof. Part (ii) shows that for \( \omega \) belonging to \( S \), the time-averaged kinetic energy displays “almost ballistic peaks” at sufficiently many time scales to force the mean growth exponent \( \alpha_0 \) to equal 2. We have no precise information on how frequent these time scales are, but expect them to be extremely rare, and hence difficult to detect numerically. Since the proof of Theorem 3.1 is based on the abstract nonsense of the previous section, we have no handle on the set \( S \) either. It should nevertheless be thought of as a set of Liouville numbers.

The main open problem in the kicked rotor is to show that for \( \omega \) a quadratic irrational and for sufficiently high coupling constant dynamical localization occurs: we unfortunately have nothing to say on that.
Proof of Theorem 3.1: It will be sufficient to check

$$U_V(\omega) = \exp -i\omega \frac{P^2}{2} \exp -iV(X)$$

satisfies the conditions of Propositions 2.3 and 2.4 with $A = P$. That $\omega \to U_V(\omega)$ is strongly continuous is immediate and since

$$PU_V(\omega)\psi = U_V(\omega)P\psi - U_V(\omega)V'\psi,$$

hypotheses (ii)-(iii) of Proposition 2.4 follow as well. Hence part (i) of Theorem 3.1 follows from Proposition 2.3. As for part (ii), since for all $\pi\omega \in \mathbb{Q}$, $\sigma_k(U_V(\omega)) = \emptyset$, the results of Last and Guarneri [G][L] show that $\forall \pi\omega \in \mathbb{Q}$ and $\forall \psi \in \ell$ $\exists C_\ell(\omega)$ so that

$$<U(\omega)^m\psi_\ell, P^2U(\omega)^m\psi_\ell> \geq C_\ell(\omega)m^2. \quad (3.10)$$

For all $\pi\omega \in \mathbb{Q}$, the mean growth exponent is therefore equal to 2. The result then follows from Proposition 2.4, provided we show that, for all $\omega$, the mean growth exponent is smaller or equal than two. This is obvious upon remarking that

$$U_V^{-m}P^2U_V^m = [P - \sum_{k=0}^{k=m-1} U_V^{-k}V'(V_V)^k]^2.$$

Note that there are other models, such as the kicked Harper model, where resonances occur, and the results can be adapted to such cases as well.

3.2 Quasiperiodic potentials

Let $\Omega$ be an $n+1$ by $n$ matrix and $W$ a continuous $\mathbb{Z}^{n+1}$-periodic real-valued function on $\mathbb{R}^{n+1}$. Define, for $x \in \mathbb{R}^n$,

$$V_{\Omega}(x) = W(\Omega x).$$

Note that, if $\Omega$ has only rational entries, there is a sublattice of $\mathbb{Z}^n$ over which $V_\Omega$ is periodic. As a result, the Schrödinger operator

$$H_\Omega = -\Delta + V_\Omega$$
on $D(H_\Omega) = D(-\Delta)$ has purely absolutely continuous spectrum. For $\psi \in D(X)$ one then has that $<\psi_t, X^2 \psi_t > \sim t^2$ (see [AK] for a detailed proof of this folk theorem). Identifying $\Omega$ with an element of $\mathbb{R}^{n(n+1)}$, it is easy to see that the hypotheses of Proposition 2.1 and Proposition 2.2 are satisfied by $H_\Omega$, taking $A = X$ and $\psi \in D(-\Delta) \cap D(X)$. As a result, there is a $G_\delta$ dense set of $\omega$ so that the mean growth exponent of $<\psi_t, X^2 \psi_t >$ is 2 and, in particular, for all strictly monotonic functions $F(T), F(T) \to \infty$, $\exists C > 0, T_k$, so that
\[
< \psi, e^{iH_\Omega T_k} X^2 e^{-iH_\Omega T_k} \psi > \geq C \frac{T_k^2}{F(T_k)}.
\] (3.11)
This is of course easily adapted to discrete Schrödinger operators and holds for the time-averaged quantities as well. In fact, combining the above with Theorem 7.1 in [L], one gets the following result on the almost Mathieu equation.

**Theorem 3.2** Let $H_{\lambda, \theta}(\omega) = -\Delta + \lambda \cos 2\pi(\omega n + \theta)$ on $\ell^2(\mathbb{Z})$, with $|\lambda| > 2$ and $\theta \in \mathbb{R}$. Then there exists a dense $G_\delta$ set of $\omega$ so that

(i) All spectral measures of $H_{\lambda, \theta}(\omega)$ are zero Hausdorff dimensional;

(ii) For all $\psi$ in a dense subset of $\ell^2(\mathbb{Z})$ contained in $D(X)$, (3.11) holds and the mean growth exponent of $<\psi_t, X^2 \psi_t >$ equals 2.

Here (i) is exactly Theorem 7.1 of [L], while (ii) improves Theorem 7.2 of [L]. It follows immediately upon taking intersections of dense $G_\delta$-sets.

### 4 The kicked linear rotor

#### 4.1 The model

Consider a particle moving on a circle $S^1$, having therefore the cylinder $M = T^*S^1 = S^1 \times \mathbb{R}$ as phase space. The Hamiltonian of the kicked linear rotor $[G][Be][B][Ho][O]$ is
\[
H(x, p, t) = \omega p + \sum_{n \in \mathbb{Z}} \delta(t - n)V(x),
\] (4.1)
where $\omega \in \mathbb{R}$ is a fixed rotation number. The corresponding Floquet map is
\[
\Phi_V(x_0, p_0) = (x_1 = x_0 + \omega, p_1 = p_0 + f(x_0)),
\] (4.2)
where $f = -V'$. Standard canonical quantization of the Hamiltonian in (4.1) leads to the following Floquet operator on $L^2(S^1, dx)$:
\[
U_V(\omega) = \exp -i\omega P \exp -iV(X).
\] (4.3)
To have some explicit examples in mind, we define, for $k \in \mathbb{N} \setminus \{0\}$,

$$Q_k(x) = \frac{1}{(2\pi i)^k} \sum_{n \in \mathbb{Z}} \frac{1}{n^k} \exp i 2\pi nx.$$ 

Then $Q_1(x) = \frac{1}{2} - x$, $0 < x < 1$, and for all $k > 1$, $Q_k$ is the unique $k$th-order polynomial satisfying $Q'_k = Q_{k-1}$, $\int_0^1 Q_k(x) dx = 0$. Note that $Q_k^{(i)}(0) = Q_k^{(i)}(1)$ for all $0 \leq i \leq k - 2$. Hence $Q_k \in C^{(k-2)}(\mathbb{S}^1)$. For example, $Q_2(x) = -\frac{1}{2}x^2 + \frac{1}{2}x - \frac{1}{12}$ and $Q_3(x) = \frac{1}{12}x(x-1)(-2x+1)$.

In order to study the asymptotic behaviour of the momentum variable in the kicked linear rotor, first note that iterating (4.2) yields

$$\Phi^m_V(x_0, p_0) = (x_m = x_0 + mw, p_m = p_0 + S(m, \omega)f(x_0)), \quad (4.4)$$

where

$$S(m, \omega)f(x_0) = \sum_{j=0}^{m-1} f(x_0 + j\omega). \quad (4.5)$$

Let us point out some immediate and simple features of this model.

First, if $\omega \in \mathbb{Q}$, then typically $p_m \sim m$ as is easily seen from (4.4)-(4.5) and the observation that the motion is then periodic in the $x$-variable. Indeed, if $\omega = r/s$, with $r, s$ relatively prime integers, then, for all $\ell \in \mathbb{N}$

$$\Phi^\ell_V(x_0, p_0) = (x_{\ell s} = x_0, p_{\ell s} = p_0 + \ell S(s \frac{r}{s})f(x_0)).$$

So $p_{\ell s} \sim \ell$ iff $S(s \frac{r}{s})f(x_0) \neq 0$.

On the other hand, if $\omega \in \mathbb{R} \setminus \mathbb{Q}$, then the motion is ergodic in the $x$-variable and hence one immediately obtains that $\lim_{m \to \infty} \frac{1}{m} S(m, \omega)f(x_0) = 0$ so that

$$\lim_{m \to \infty} \frac{p_m}{m} = 0. \quad (4.6)$$

In short, when $\omega$ is rational, the motion is ballistic on the cylinder, whereas it is subballistic if $\omega$ is irrational.

Note however that, even though $p_m = o(m)$ it is still conceivable that $\sup_m |p_m| = \infty$. Moreover it is well known from the Denjoy-Koksma inequality that $\liminf_m |p_m| < C < \infty$ if $f = -V' \in C^1(\mathbb{S}^1)$. Hence the classical dynamics would in such a case correspond to the point $(x_m, p_m)$ wandering all over the cylinder, up and down the $p$ axis, leaving every bounded set at some times and returning close to the origin at some other times. This behaviour is thought of as unusual since it can not occur in systems with
time-independent Hamiltonians [RS III]; one expects it to be reflected in
the quantum model through the presence of singular continuous spectrum,
a fact we shall prove below.

The asymptotics for the classical dynamics of the kicked linear rotor was
studied in detail in [DBF]. We shall show here that the analysis carries over
to the quantum model and study the spectral and dynamical (in)stability
of the model.

Before turning to this task, we show the quantum equivalent of (4.6).
We need a preliminary technical lemma. Let
\[ D(P) = \{ \psi = \sum c_n \exp i 2\pi n x \in L^2(S^1, dx); \sum n^2 |c_n|^2 < \infty \}. \]

**Lemma 4.1** If \( \psi \in D(P) \) and if \( V, V' \in L^2(S^1) \), then \( U_{V'}^m \psi \in D(P) \forall m \in \mathbb{N} \).

Moreover,
\[ < \psi, U_{V'}^m P U_{V'}^m \psi > = < \psi, S(m, \omega) f(X) \psi > + < \psi, P \psi > \quad (4.7) \]
and
\[ \| PU_{V'}^m \psi \|^2 = < U_{V'}^m \psi, P^2 U_{V'}^m \psi > = \| P \exp -iS(m, \omega) V(X) \psi \|^2, \quad (4.8) \]
where \( \| \cdot \| \) denotes the \( L^2 \)-norm.

**Proof**: First we compute
\[ U_{V'}^m = \exp -i \omega P m \exp -i \sum_{k=0}^{m-1} V(X + k\omega) \]
\[ = \exp -i \sum_{k=1}^{m} V(X - k\omega) \exp -i \omega P m. \quad (4.9) \]

Now, if \( \psi \in D(P) \), then \( \psi \in L^\infty(S^1) \), so \( f(x - k\omega) \psi(x - m\omega) \in L^2(S^1, dx) \)
since \( f \in L^2(S^1, dx) \). In conclusion
\[ P(U_{V'}^m \psi)(x) = \sum_{k=1}^{m} f(x - k\omega)(U_{V'}^m \psi)(x) + (U_{V'}^m (P \psi))(x) \]
belongs to \( L^2(S^1, dx) \); (4.7) follows immediately from this. Using the first relation in (4.9), (4.8) follows as well.
Proposition 4.2: If \( \psi \in \mathcal{D}(P) \), if \( V, V' \in L^2(S^1) \), and if \( \omega \) is irrational one has, as \( m \to \infty \),
\[
\frac{1}{m} < \psi, U^{-m}_V PU^m_V \psi > \to 0 \tag{4.10}
\]
and
\[
\frac{1}{m^2} \| PU^m_V \psi \|^2 \to 0. \tag{4.11}
\]

Proof: Since \( \int_{S^1} f(x) dx = 0 \) and \( f \in L^2(S^1, dx) \) it follows from the Von Neumann mean ergodic theorem that \( m^{-2} \| S(m, \omega) f \|_2^2 \overset{m \to \infty}{\to} 0 \). Hence, using (4.8), one has (4.11) since \( \psi \in \mathcal{L}^\infty(S^1) \). The proof of the first statement is similar. \( \square \)

Clearly (4.10)-(4.11) are the quantum analogs of (4.6). For rational \( \omega \), one sees from (4.7) that, as in the classical case, \( < \psi, U^{-m}_V PU^m_V \psi > \sim m \) for typical potentials \( V \); we shall say that a potential \( V \) is a typical potential provided the function \( S(s, \frac{r}{s})V \) is not constant on a set of positive measure for any \( r, s \) as above. Note that it follows from our discussion above that this is equivalent to requiring that \( p_m \sim m \) for all rational \( \omega \) and for almost all initial values \( x_0 \). Putting an appropriate topology on the set of all potentials one can show that the typical potentials form a dense \( G_\delta \) set, but we shall not be interested in that any further. It is perhaps more interesting to remark that the potentials \( Q_k \) introduced above are typical. Indeed, it is easy to compute
\[
S(s, \frac{r}{s})Q_k(x) = s^{1-k}Q_k(sx),
\]
from which the conclusion follows.

4.2 Spectral (in)stability

We are now ready to settle the spectral stability question for the kicked linear rotor. The result is summarized in the following theorem.

Theorem 4.3 Let \( U_V(\omega) = \exp -i\omega P \exp -iV(X) \) with \( V, V' \in L^2(S^1) \), i.e. \( V \in H^1(S^1) \). Then

(i) For typical \( V \) and for all \( \omega \in Q \), \( \sigma_{pp}(U_V(\omega)) = \emptyset = \sigma_{sc}(U_V(\omega)) \); i.e. \( L^2(S^1) = \mathcal{H}_{sc}(U_V(\omega)) \);

(ii) If \( \omega \in \mathbb{R} \setminus Q \), then \( \sigma_{ac}(U_V(\omega)) = \emptyset \) and in addition either \( L^2(S^1) = \mathcal{H}_{sc}(U_V(\omega)) \) or \( L^2(S^1) = \mathcal{H}_{pp}(U_V(\omega)) \);

(iii) For typical \( V \), there exists a dense \( G_\delta \) set of \( \omega \) so that \( L^2(S^1) = \mathcal{H}_{sc}(U_V(\omega)) \) (i.e. \( \sigma_{ac}(U_V(\omega)) = \emptyset = \sigma_{pp}(U_V(\omega)) \));
(iv) If $V \in H^s(S^1)$, $s > 1$, then $L^2(S^1) = \mathcal{H}_{pp}(U_V(\omega))$ (i.e. $\sigma_{ac}(U_V(\omega)) = \emptyset = \sigma_{sc}(U_V(\omega))$) for Lebesgue almost all $\omega$.

**Proof:** Part (i) is the spectral pendant of the observation made above that for rational $\omega$, and for typical $V$, the motion is ballistic: $p_m \sim m$. If $\omega = r/s$ with $r$ and $s$ relatively prime integers, then it is easy to see that the spectrum of $U_V(\omega)$ is organized in bands, and has no singular continuous part [IS][Be]. To see that, for typical $V$, it has no eigenvalues either, we proceed as follows. First, (4.9) implies

$$U_V(\omega)^s = \exp \left( -i \sum_{k=0}^{s-1} V(X + k\frac{r}{s}) \right).$$

Consequently, it is clear that, provided the function $S(s, \frac{r}{s})V$ is not constant on a set of positive measure, the spectrum of $U_V(\omega)^s$ is purely absolutely continuous. In that case, the same holds for the spectrum of $U_V(\omega)$ itself.

More interesting is the case where $\omega \in \mathbb{R} \setminus \mathbb{Q}$. To prove (ii), recall that the aforementioned result of Guarneri and Last, and more precisely Theorem 6.1 in [L] implies that, if the spectral measure of $\psi$ contains an absolutely continuous component, then necessarily

$$\langle \psi, U_V^{-m} P^2 U_V^m \psi \rangle \geq C m^2, \quad \forall m \in \mathbb{Z},$$

for some $C > 0$. This being incompatible with (4.11), we conclude that $\sigma_{ac}(U_V(\omega))$ is empty, proving the first statement in (ii); (iii) now follows immediately from this, Proposition 4.3, and (i).

The second part of (ii) is easily proven as follows. Suppose $\lambda \in \sigma_{pp}(U_V(\omega))$ and let $\psi$ be the corresponding eigenfunction, then

$$U_V \psi(x) = \exp -i V(x - \omega) \psi(x - \omega) = \lambda \psi(x). \quad (4.12)$$

Taking absolute values on both sides yields

$$|\psi|(x - \omega) = |\psi|(x), \quad \forall x \in [0, 1[.$$

Since $\omega$ is irrational, this implies $|\psi|(x) \equiv \text{cst}$, so that $\psi(x) = \exp -i W(x)$ for some $W$. Reinserting this into (4.12), one has

$$\exp -i V(x - \omega) = \lambda \exp -i W(x) \exp i W(x - \omega)$$

and hence

$$U_V(\omega) = \lambda \exp -i W(X) \exp -i \omega P \exp i W(X). \quad (4.13)$$
So \( U_V(\omega) \) is unitarily equivalent to \( \lambda \exp -i\omega P \), which of course has pure point spectrum. In conclusion, if \( \omega \in \mathbb{R} \setminus \mathbb{Q} \), we know that either \( \sigma_c(U_V(\omega)) = \emptyset \), or \( \sigma_{pp}(U_V(\omega)) = \emptyset \); the spectrum is therefore either purely singular continuous or exclusively pure point. We have already shown that the first case occurs on a dense \( G_\delta \) set. We now show the second case occurs as well.

One expects the spectrum to be pure point for \( \omega \) poorly approximated by the rationals. To prove this, first remark that it follows from (4.13) that it suffices to solve

\[
V(x) = W(x) - W(x - \omega)
\]

for \( W \in L^2(S^1) \). Assuming \( V \in H^s(S^1), s > 1 \) and that \( q_{k+1} = O(q_k^{1+\gamma}) \) with \( 1 + \gamma < s \) such a solution exists as is easily seen upon Fourier transforming the equation and solving for the Fourier coefficients of \( W \). It is then easy to see that \( U_V(\omega) \) is of the form (4.13) with \( \lambda = 1 \). Here the \( q_k \) are the denominators of the continuous fraction approximants of \( \omega \). Since the condition \( q_{k+1} = O(q_k^{1+\gamma}) \) holds Lebesgue a.e. (Theorem 32 in [K]), (iv) follows.

\[ \square \]

**Remark:** A version of part (i) of this result is proven in [Ho][Be]. Absolute continuity of the spectrum implies [Gu][L] that \( \forall \psi \in D(P), \)

\[
< \psi, U_V^{-m} P^2 U_V^m \psi > \geq C m^2, \quad \forall m \in \mathbb{Z},
\]

a fact we will prove more directly below. Part (ii) is an improvement over [Be], where the result is proven on the one hand for all irrational \( \omega \) under the hypothesis that \( V \in C^1 \), \( \int_{S^1} |V'| |(x)| dx < 2\pi \) and on the other hand, for almost all \( \omega \in \mathbb{R} \setminus \mathbb{Q} \), provided \( V \in C^2(S^1) \). Our result here shows that \( V' \in L^2(S^1) \) suffices and that the condition on the total variation of \( V \) can be removed. Note that some smoothness of \( V \) is at any rate needed: it is metioned in [Be] and easily confirmed that for \( V(x) = 2\pi x, \quad x \in [0,1[ \), the spectrum of \( U_V \) is a.c. even for irrational \( \omega \). Note however that, viewed as a function on \( S^1 \), this potential does not have an \( L^2 \) derivative because of the jump discontinuity. For typical \( V \in C^2(S^1), \quad \int |V'| dx < 2\pi \), (iii) is proven in [O] using the results of [CG] and [Be].

### 4.3 Dynamical (in)stability

We are interested in the behaviour of \( < U_V^m \psi, P^2 U_V^m \psi > \). First remark that the results of section 2 immediately imply that, generically in \( \omega \), the mean growth exponent of this quantity equals 2. To get sharper estimates, we now use the results of [DBF]. If the Fourier coefficients \( v_n \) of \( V \) satisfy
\(v_n \sim |n|^{-\nu+1}\) for some \(\nu > 1/2\), it is an immediate consequence of Theorem 1.1(i) of [DBF] that for a class \(\mathcal{R}_\infty\) of explicitly described Liouville \(\omega\) and for all \(\epsilon > 0\), there exists a constant \(C_\epsilon\) so that
\[
< \psi_\ell, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi_\ell > \geq C_\epsilon \ m^{2/1+\nu-\epsilon}, \ \forall m,
\]
where \(\psi_\ell(x) = \exp i2\pi \ell x\). Here \(\omega \in \mathcal{R}_\infty\) if and only if the denominators \(q_k\) of its continued fraction expansion satisfy
\[
\forall \gamma > 0, \ \exists R_\gamma > 0 \mathrm{so}\mathrm{that} \ q_{k+1} > \frac{q_k^{1+\gamma}}{R_\gamma}.
\]
Moreover, Theorem 1.2(ii) in [DBF] implies that, for the same \(\omega\),
\[
\frac{2}{1+\nu} \leq \alpha_- = \liminf_{m \to \infty} \frac{\log < \psi_\ell, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi_\ell >}{\log m} \leq \frac{2}{1/2+\nu}.
\]
Using (1.5) this implies that \(\dim H \mu_\psi \leq \frac{1}{1/2+\nu}\). At the same time, and still for the same \(\omega\), Theorem 1.1 in [DBF] yields
\[
\alpha_+ = \limsup_{m \to \infty} \frac{\log < \psi_\ell, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi_\ell >}{\log m} = 2.
\]
Summarizing the result loosely, we see that \(< \psi_\ell, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi_\ell >\) oscillates quite a bit, between \(m^2\) and \(m^{2+\nu+1/2}\), staying always at least as high as \(m^{2+\nu}\).

Note again that the upper bound on the Hausdorff dimension of the spectral measure \(\mu_\psi\) does not exclude the existence of almost ballistic peaks, a phenomenon already observed in [L] and in Theorem 3.2 above.

If \(V \in C^\infty\), then Theorem 1.2 (ii) of [DBF] shows that, for all \(\omega \in \mathbb{R} \setminus \mathbb{Q}\), \(\alpha_- = 0\), implying, via (1.5), that the Hausdorff dimension of \(\mu_\psi\) vanishes. So in this case, the Hausdorff dimension takes on only two values: it is equal to 1 if \(\omega\) is rational and equal to 0 otherwise. At the same time, the results of section 2 tell us that for generic values of \(\omega\), \(\alpha_0 = 2 = \alpha_+.\) This shows in an even stronger way than the example of section 3.2 that no upper bounds on \(< \psi, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi >\) can be expected in terms of information on the fractal dimension of the spectral measures.

These results show that \(< \psi, U_V(\omega)^{-m} P^2 U_V(\omega)^m \psi >\) tends to fluctuate enormously. It is legitimate to speculate that this is a feature common to the solution of Schrödinger equations with propagators having “unusual”
spectrum. Note however that detecting such fluctuations numerically might be an impossible task: the times at which they are proven to occur (see [DBF]) behave like \(q_k\), where the \(q_k\) are the denominators of the convergents of the continued fraction expansion of \(\omega\), which grow extremely fast for the \(\omega\) considered.

To end this section, we should point out that the results in [DBF] actually concern the asymptotic behaviour of \(<\overline{\mathbf{p}}_m>^2\), where

\[<\overline{\mathbf{p}}_m>^2 = \int_{S^1} |\mathbf{p}_m(x_0)|^2 \, dx_0.\]

This is clearly determined by the asymptotic behaviour of the \(L^2\)-norm of the time-average of \(S(m,\omega)f\). It turns out that this quantity has the same asymptotic behaviour as \(<\overline{\psi}_m^\ell,U_m^2U_m^\ell\psi>\), as we now briefly show. First compute, using (4.8)

\[
|| S(m,\omega)f(X)\psi || - || P\psi ||^2 \leq <U_m^\ell\psi,P^2U_m^\ell\psi> \leq || S(m,\omega)f(X)\psi || + || P\psi ||^2.
\]

Averaging over \(m\) and a short computation then yield

\[
\left(\frac{1}{m} \sum_{k=1}^{m} || S(k,\omega)f(X)\psi ||^2\right)^{1/2} - || P\psi ||^2 \leq \frac{1}{m} \sum_{k=1}^{m} <U_m^\ell\psi,P^2U_m^\ell\psi> \leq \left(\frac{1}{m} \sum_{k=1}^{m} || S(k,\omega)f(X)\psi ||^2\right)^{1/2} + || P\psi ||^2,
\]

from which it is clear that the asymptotic behaviour of \(<U_m^\ell\psi,P^2U_m^\ell\psi>\) is determined by the one of \(|| S(m,\omega)f(X)\psi ||^2\). Assuming that \(|\psi|(x) = 1, \ \forall x\), which is in particular true when \(\psi\) is a momentum eigenstate \(\psi_\ell(x)\), one simply has \(|| S(m,\omega)f(X)\psi_\ell || = || S(m,\omega)f(X) ||\) so that the averaged kinetic energy is then determined by the time-averaged \(L^2\)-norm of \(S(m,\omega)f(X)\). It turns out that this has the same asymptotic behaviour as the \(L^2\)-norm of the time-average of \(S(m,\omega)f\). To see this, note that a simple computation shows that

\[
|| \frac{1}{M} \sum_{m=1}^{M} S(m,\omega)f(X) ||^2 = \sum_{n \in \mathbb{Z}} |f_n|^2 G_M(n\omega),
\]

with

\[
G_M(x) = \frac{1}{4\pi \sin^2 \frac{\pi x}{M}} \left| 1 - \frac{\sin \pi M x}{M \sin \pi x} \exp i\pi M x \right|^2.
\]
whereas
\[ \frac{1}{M} \sum_{m=1}^{M} \| S(m, \omega) f(X) \|^2 = \sum_{n \in \mathbb{Z}} | f_n |^2 H_M(n\omega), \]
with
\[ H_M(x) = \frac{1}{2 \sin^2 \pi x} \left[ 1 - \frac{\cos \pi x (M + 1) \sin \pi x M}{M \sin \pi x} \right]. \]

It then suffices to notice that the proofs of [DBF] are entirely based on the following estimates for \( G_M(x) \) (Lemma 2.1 in [DBF])
\[ \frac{c}{\sin^2 \pi x} \leq G_M(x) \leq \frac{C}{\sin^2 \pi x}, \quad \forall 1/M \leq x \leq 1/2 \]
and
\[ \frac{cM^2}{\sin^2 \pi x} \leq G_M(x) \leq \frac{CM^2}{\sin^2 \pi x}, \quad \forall 0 \leq x \leq 1/M, \]
with the upper bound holding for all \( x \in \mathbb{R} \). The same inequalities hold for \( H_M(x) \) as well, as is easily checked. It follows that the quantum and classical dynamics in this model are essentially the same. This is not too surprising if one compares \( p_m = p_0 + S(m, \omega) f(x_0) \) to (4.7), which can be rewritten suggestively as (see also [O])
\[ P_m \equiv U_V^{-m} P_0 U_V^m = P_0 + S(m, \omega) f(X_0). \]

5 A one-band tight binding model in a time-dependent electric field

In this section we turn our attention to the one-dimensional tight-binding model with time-dependent electric field \( E(t) \) given by
\[ [H(t)\psi]_n = \sum_{k \in \mathbb{Z}} a_{n-k} \psi_k + E(t)n\psi_n. \quad (5.1) \]

Here the off-diagonal matrix elements \( a_n \) of the Hamiltonian are assumed to belong to \( \ell^2(\mathbb{Z}) \) and \( a_n = a_{-n} \). The corresponding time-dependent Schrödinger equation
\[ i\partial_t \psi_t = H(t)\psi_t, \quad (5.2) \]
can be solved explicitly in several ways [DK]. We proceed as follows. Fourier transforming of (5.2) yields
\[ i\partial_t \hat{\psi}_t = \hat{H}(t)\hat{\psi}_t, \]
where, for \( x \in [0, 1] \equiv S^1 \),
\[
\hat{\psi}(x) = \sum_n \psi_n \exp i 2\pi nx \in L^2(S^1, dx),
\]
\[
\hat{a}(x) = \sum_n a_n \exp i 2\pi nx \in L^2(S^1, dx),
\]
\[
\hat{H}(t) = \frac{E(t)}{2\pi} P + \hat{a}(x), \quad P = \frac{d}{i \, dx}.
\]

We chose to use the unusual notation “\( x \)” for the quasi-momentum in order to bring the analogy with the previous section out more clearly, as follows. Solving the Schrödinger equation yields
\[
\hat{\psi}_t = U_t \hat{\psi}_0, \quad (5.3)
\]
where
\[
U_t = \exp -i G(t) P \exp -i W_t(X), \quad (5.4)
\]
and
\[
G(t) = \frac{1}{2\pi} \int_0^t E(s) ds; \quad W_t(x) = \int_0^t \hat{a}(x + G(s)) ds. \quad (5.5)
\]

We now concentrate on smooth periodic field amplitudes \( E(t) \) of period \( T \) for which we write
\[
E(t + T) = E(t); \quad E(t) = E_0 + e(t); \quad e(t) = \sum_{n \in \mathbb{Z}^*} e_n \exp \frac{i 2\pi}{T} nt. \quad (5.6)
\]

The Floquet operator \( U_T \) is then given by
\[
U_T = \exp -i \tau P \exp -i W_T(x), \quad \tau = \frac{E_0 T}{2\pi}. \quad (5.7)
\]

The analogy with the previous section, and in particular with (4.3) is now completely clear. We shall be interested in the asymptotic behaviour of
\[
< \psi_t, N^2 \psi_t > = \sum_{n \in \mathbb{Z}} n^2 \left| \psi_{tn} \right|^2 = \frac{1}{(2\pi)^2} < \hat{\psi}_t, P^2 \hat{\psi}_t >, \quad (5.8)
\]
for \( \psi_0 \in \mathcal{D}(N) \). For this expression to make sense, we need that \( \psi_t \in \mathcal{D}(N) \).

A sufficient condition to ensure that \( \mathcal{D}(N) \) is invariant under \( U_t \) is given by Lemma 4.1: \( na_n \in l^2(\mathbb{Z}) \).

Note first that, if \( E_0 = 0 \), it is well known that \( < \psi_t, N^2 \psi_t > \sim t^2 \), except if \( e(t) = E_1 \cos \frac{2\pi}{T} t, \quad a_n = \delta_{1,n} + \delta_{-1,n} \) and with very special choices of \( T \) and \( E_1 \) [DK]. If, on the other hand, \( e(t) = 0 \), one readily sees that \( \sup_t < \psi_t, N^2 \psi_t > < C \). We will consider the intermediate situation where \( E(t) = E_0 + E_1 \cos \frac{2\pi}{T} t \) and \( E_1 > E_0 > 0 \), to obtain the following result.
Theorem 5.1 Suppose \( a_n \geq c | n |^{-\nu} \) for some \( c > 0 \) and \( \nu > 3/2 \). Then there exists a set of Liouville \( \omega \) so that the following holds. Given \( \omega \) in this set and given \( E_0 \), there exists a countable and dense set of values of \( E_1 \) in \([E_0, \infty]\) so that for all \( \epsilon > 0 \) and \( \forall \ell \in \mathbb{Z} \), there exists \( C > 0 \) so that,

\[
< \delta_\ell, U_T^{-m} N^2 U_T^m \delta_\ell > \geq Cm^{\frac{2}{\nu} - \epsilon},
\]

Here \( C \) depends on \( \epsilon, \ell, E_0, \omega \) and \( E_1 \).

Note that, as \( \nu \to 3/2 \), the exponent approaches 1 from below, so that under our hypotheses the motion is always subdiffusive. The lower bound on \( \nu \) ensures that the evolution leaves the domain of \( N \) invariant.

Proof: Comparing (5.4) to (4.3), it is clear that, in order to apply the results of section 4.3, we need to get a lower bound on the Fourier coefficients \( w_n = \overline{w}_{-n} \) of \( W_T(x) \):

\[
w_n = a_n \int_0^T \exp \left[ i n \left( E_0 t + \frac{E_1}{\omega} \sin \omega t \right) \right] dt.
\]

To control the integral, we use a stationary phase argument. Since we assume \( E_1 > E_0 \), the phase has two stationary points \( 0 < t_- < t_+ < T \):

\[E_0 + E_1 \cos \omega t_\pm = 0.\]

Taking small open intervals \( \Delta_\pm \subset [0, T] \) around \( t_\pm \) so that \( \Delta_+ \cap \Delta_- = \emptyset \), one can construct a smooth partition of unity on \( \mathbb{R}/T\mathbb{Z} \) so that

\[\varphi_- + \varphi_0 + \varphi_+ = 1,\]

where \( \text{supp} \varphi_\pm \subset \Delta_\pm \), \( 0 \leq \varphi_\epsilon \leq 1 \in C^\infty \) and where \( \varphi_\pm(t) = 1 \) on a small subinterval of \( \Delta_\pm \) containing \( t_\pm \). Then

\[
\int_0^T \exp i2\pi n G(t) \ dt = I_0^n + I_+^n + I_-^n,
\]

with obvious notations. Since we know that, on the support of \( \varphi_0 \), \( |G'(t)| \) is bounded away from 0, an integration by parts shows that \( |I_0^n| = O(|n|^{-1}) \).

For \( I_\pm^n \), a stationary phase argument shows that

\[
I_\pm^n = \sqrt{\frac{1}{n \ | G''(t_\pm) \ |}} \exp i2\pi n G(t_\pm) \exp i\frac{\pi}{4} \text{sgn} G''(t_\pm) + o(|n|^{-1/2}).
\]
Since $G''(t_+) = -G''(t_-) > 0$ one finds
\[
\int_0^T \exp i2\pi nG(t) \, dt = \sqrt{\frac{2\pi}{n\omega(E_1^2 - E_0^2)^{1/2}}} \exp i\frac{\pi}{4} \exp i2\pi nG(t_+)[1 - i\exp in\Phi(E_1)]
+ o(|n|^{-1/2})
\]
where, for $E_0$ and $\omega$ fixed,
\[
\Phi(E_1) = E_0(t_+ - t_-) + \frac{2E_1}{\omega} \sin \omega t_-
\]
Since $\Phi$ is a monotonically increasing continuous function of $E_1$, mapping $]E_0, \infty[ \text{ onto } ]0, \infty[$, one can choose $E_1$ so that $\Phi(E_1) = 2\pi \frac{p}{q}$, with $p, q \in \mathbb{N}$ and $q$ different from 0 modulo 4, which guarantees that
\[
\inf_n |[1 - i\exp in\Phi(E_1)]| > 0
\]
from which one concludes that
\[
|\int_0^T \exp i2\pi G(t) \, dt| \geq C \frac{1}{\sqrt{n}}.
\]
This implies $w_n \geq n^{-\nu+1/2}$, so that (5.8) and (4.14) yield the result of the Theorem. \qed
