Abstract: In this paper, we consider the stationary density function of the doubly skew Ornstein-Uhlenbeck process. We present the explicit formula for the stationary density function and show that this process is positive Harris recurrent and geometrically ergodic. We expand our method to the more general cases in which the parameters are present and we try to consider the stability of the skew Ornstein-Uhlenbeck process whose parameters depend on a finite-state and irreducible continuous-time Markov chain. Then we offer the stationary distribution equation of this bivariate process through their infinitesimal generator and the explicit stationary distributions are list as a special case.

Keywords: doubly skew Ornstein-Uhlenbeck process, markov-modulated process, stationary distribution.

1. Introduction

Skew diffusions have drawn attention in fields of financial engineering, physics, mathematical biology, etc. because of their potential applications, for example, [10], [13], [12], and [8]. The skew Brownian motion (abr. skew BM) was first introduced by K. Ito and H. P. Mckean in [6], which is a simple but interesting diffusion process. The doubly skewed OU process is an extension of the skew Brownian motion. A general class of stochastic differential equations involving the local times of unknown process was first proved by Le Gall [5], and then developed by Barlow [11], Engelbert and Schmidt [4], Lejay [2], Bass and Chen [14] and many others.

We denote by $(\Omega, \mathcal{F}, \mathbb{P})$ a complete probability space and the filtration $\{\mathcal{F}_t, t \geq 0\}$ is assumed to satisfy the usual conditions. For a process $X = \{X_t, t \geq 0\}$, the notation $(X_t, \mathcal{F}_t)$ signifies that $X$ is adapted to the filtration $\{\mathcal{F}_t\}$. For parameters $\gamma, \sigma > 0, b > a, |\xi|_2 < 1$, we define the doubly skewed Ornstein-Uhlenbeck (abr. skew OU) process $(X_t, \mathcal{F}_t)$ as a weak solution to

$$dX_t = \gamma X_t dt + \sigma dB_t + (2p_1-1)d\tilde{L}_t^a(a) + (2p_2-1)d\tilde{L}_t^b(b),$$

(1)

where $B_t$ is a standard Brownian motion on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and $\tilde{L}_t^a(a)$ (resp. $\tilde{L}_t^b(b)$) is the symmetric local time at $a$ (resp. $b$). It is well-known that for $p_1 = 0$ or $p_2 = 0$, the equation (1) is the skew OU process whose weak existence and pathwise uniqueness have been proved by S.Wang [16]. The aim of this paper is to elaborate the stationary of this kind of process.

When computing the stationary distribution, Karlin and Taylor [15] offered a classical method which is not suitable for our process. We use the infinitesimal generator of doubly skewed OU process to derive the stationary density function. Then we expand our method to more general doubly skewed OU process and the Markov-modulated skew OU process (abbr. MMSOU). There are a large amount of papers concentrating on Markov modulated process, because such a process can capture the switching of the market conditions. Many scholars investigate their applications in finance. For example, [3] and [7] studied how to price options.

The paper is organized as follows. Section 2 is concentrated on the explicit stationary density of doubly skewed OU process, under the drift coefficient has only one parameter. Section 3 expands to the multiple-parameter case. Section 4 discusses the stability of the MMSOU, here we mainly consider the stability in distribution.

2. Stationary distribution for the doubly skewed process

A doubly skewed OU process which starts from any initial point in its state space behaves like the ordinary OU process until it reaches the skew point $a$ (resp. $b$), causing upwards with probability $p_1$ (resp. $p_2$) and downwards with probability $1 - p_1$ (resp. $1 - p_2$). In this section, we will derive the stationary density function of the doubly skewed OU process $(X_t)$ defined in (1). Before giving the theorem about the stationary density of process $(X_t)$, we first introduce some basic definitions.

Definition 2.1. The Markov process $\Phi$ is called ergodic if an invariant probability $\pi$ exists and

$$\lim_{t \to \infty} \| P^t(y, \cdot) - \pi \| = 0, \ y \in \mathbb{E},$$

and is called geometrically ergodic if for some $B < \infty, \beta < 1,$
Theorem 2.2. The doubly skew OU process \( \{X_t\} \) defined in (1) is positive Harris recurrent and \( V \)-uniform ergodic.

Proof. Let \( C \) be the set of functions \( f \in C_c(R), \)

\( f', f'' \in C_c(R) \cap (a, b) \) and \( f'' \) satisfies \( p_1 f''(a-)=0, p_2 f''(b-)=0 \), at points \( a \) and \( b \). Recall that \( I=(0,\infty) \). For \( f \in C \), applying the generalized Ito formula to \( f(X_t) \), we have

\[
df(X_t) = f'(X_t)dX_t + \frac{1}{2}f''(X_t)d\langle X \rangle_t + \frac{1}{2}f'(a-)f'(a-)d\xi^X_t(b)
\]

where the last equality holds because of the fact

\[
(2p_1-1)f'(X_t)d\xi^X_t(a)+(2p_2-1)f'(X_t)d\xi^X_t(b)
\]

\[
+\frac{1}{2}[f'(a-)-f'(a-)d\xi^X_t(a)+\frac{1}{2}[f'(b+)-f'(b-)d\xi^X_t(b)
\]

\[
=\gamma X_t f'(X_t)ds + \sigma f'(X_t)dB_t + \xi f'(X_t)d\xi^X_t(a) + \frac{1}{2}[f'(a-)+f'(a-)d\xi^X_t(a)+\frac{1}{2}[f'(b+)+f'(b-)d\xi^X_t(b)
\]

\[
=\gamma X_t f'(X_t)ds + \sigma f'(X_t)dB_t + \frac{1}{2}f'(X_t)\sigma^2ds,
\]

where \( \xi \) is the generator of \( \{X_t\} \) is positive Harris recurrent and geometrically ergodic, and the density of the unique stationary distribution for \( X_t \) is as follows:

\[
f(x) = \int_{-\infty}^{\infty} e^{\frac{x^2}{2}} \frac{1}{\sqrt{2\pi}} \, dx
\]

where

\[
q(x) = \int_{-\infty}^{\infty} e^{-\frac{x^2}{2}} \, dx
\]

Theorem 2.3. The doubly skewed OU process \( \{X_t\} \) defined in (1) is positive Harris recurrent and geometrically ergodic, and the density of the unique stationary distribution for \( X_t \) is as follows:

\[
q(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}
\]

Finally, considering the condition \( \int_{-\infty}^{\infty} q(x) \, dx = 1 \), we get the
unique stationary density \( q(x) \) given by (4).

3. Extension to multiple-parameter case

The method can be extended to the more general cases in which the multiple parameters are presented. We consider the following general doubly skew OU process:

\[
dX_t = (\alpha - \gamma X_t)dt + \sigma dB_t + (2p_1 - 1)d\tilde{L}^x_t(a) + (2p_2 - 1)d\tilde{L}^x_t(b),
\]

where \( \tilde{L}^x_t(a) \) and \( \tilde{L}^x_t(b) \) are the local time at \( a \) and \( b \), respectively. In the above model, our goal is to derive the stationary density of joint parameters \( a \) and \( \gamma \).

**Theorem 3.1.** The doubly skewed OU process \( X_t \) defined in (5) is positive Harris recurrent and geometrically ergodic, and the density of the unique stationary distribution for \( X_t \) is as follows:

\[
q(x) = \begin{cases} 
\frac{(1-p_1)(1-p_2)}{\Lambda} e^{\frac{x}{\gamma} - \frac{a}{\gamma} x}, & -\infty < x < a, \\
\frac{p_1(1-p_2)}{\Lambda} e^{\frac{x}{\gamma} - \frac{a}{\gamma} x}, & a < x < b, \\
\frac{p_2(1-p_2)}{\Lambda} e^{\frac{x}{\gamma} - \frac{a}{\gamma} x}, & x > b,
\end{cases}
\]

where

\[
\Lambda = (1-p_1)(1-p_2) \int_{-\infty}^{\infty} e^{\frac{x}{\gamma} - \frac{a}{\gamma} x} dx + p_1(1-p_2) \int_{a}^{\infty} e^{\frac{x}{\gamma} - \frac{a}{\gamma} x} dx + p_2(1-p_2) \int_{b}^{\infty} e^{\frac{x}{\gamma} - \frac{a}{\gamma} x} dx.
\]

**Proof.** Let \( C \) be the set of functions \( f \in C_b(R) \), \( f, f' \in C_b(R) \setminus (a,b) \) and \( f \) satisfies \( p_1f(a) = (1-p_1)f(a) \), \( p_2f(b) = (1-p_2)f(b) \), at points \( a \) and \( b \). Recall that \( I = (0, \infty) \). For \( f \in C \), applying the generalized Ito formula to \( f(X_t) \), we have

\[
df(X_t) = f'(X_t)dX_t + \frac{1}{2} f''(X_t)d\{X_t\} + \frac{1}{2} f'(a) - f'(b) dl_t^x(a)
\]

then

\[
f(X_t) = f(X_0) + \int_0^t [f'(X_s)ds + \int_0^s (f'(X_u)du) + \int_0^s f''(X_u)dl_t^x(a)] dX_s.
\]

For any \( f \in C \), the infinitesimal generator of \( \{X_t, t \geq 0\} \) is defined by

\[
Af(x) = \lim_{t \rightarrow \infty} \frac{E_t f(X_t) - E_t f(X_0)}{t} = \frac{1}{2} \sigma^2 f''(x) + (\alpha - \gamma x) f'(x),\ x \in C.
\]

4. Extension to the Markov-modulated skew OU process case

In this section, we consider the stability of a skew OU process \( \{X_t, t \geq 0\} \), whose parameters depend on a finite-state and irreducible continuous time Markov chain \( \{J_t, t \geq 0\} \). We first define the MMSOU \( \{X_t, J_t\}, t \geq 0 \) on the state space \( R \times E \), where \( E = \{1, 2, ..., N\} \) for some finite integer \( N \). Suppose that \( (\Omega, F, P) \) is a filtered probability space with the filtration \( \{F_t, t \geq 0\} \) satisfying the usual condition. The first component is also called observable process, \( X_t \), which satisfies the following stochastic differential equations (abbr. SDE) with local time

\[
dX_t = (\alpha - \gamma X_t)dt + \sigma dB_t + (2p_1 - 1)d\tilde{L}^x_t(a), a > 0, \sigma > 0, \alpha \in (0,1), \]

where \( B_t \) is a standard Brownian motion and \( \tilde{L}^x_t(a) \) is the symmetric local time at \( a \). The second component of the bivariate process, \( J_t \), is an irreducible right-continuous Markov chain taking values in \( E = \{1, 2, ..., N\} \) defined on the same probability space. In addition, assume that \( J_t \) and \( B_t \) are independent. For \( J = i, i \in E, J_{t+} > 0 \) are some constants and \( \tilde{L}^x_t(a) \) is the symmetric local time. The Markov chain \( J_t \) is characterized by its generator \( V = (v_{ij})_{i \neq j} \) satisfying

\[
W = \{J_{t+} = j | J_t = i\} = \left\{ v_{ij} \Delta + o(\Delta), \quad if \ i \neq j, \right. \\
(1 + v_{ij})\Delta + o(\Delta), \quad if \ i \neq j, \\
\]

Where \( \Delta > 0 \) and \( v_{ii} > 0 \) is the transition rate from \( i \) to \( j \) if \( i \neq j \), \( v_{ij} = \sum_{j=1}^{N} v_{ij} < 0 \).

Let \( \pi = (\pi_1, \pi_2, ..., \pi_N) \) be the stationary distribution of \( J_t \). Because we have assumed that \( J_t \) is an irreducible
is the stationary distribution of \( (X_t, J_t) \).

The infinitesimal generator of the Markov process \( \{(X_t, J_t)\} \) is defined as follows:

\[
(Af)(x,i) = \lim_{t \to 0} \frac{1}{t} \left[ E_{x,i} f(X_t, J_t) - E_{x,i} f(X_0, J_0) \right].
\]

For any \( f \in C \), using the Ito Tanaka formula, we obtain

\[
E_{x,i} f(X_t, J_t) - E_{x,i} f(X_0, J_0) = (1 + v_t^i) E_{x,i} f(X_0, J_0) + \sum_{j \neq i} v_{ij} E_{x,j} f(X_0, J_0) - E_{x,i} f(X_0, J_0) + \int_0^t \int_{\mathbb{R}^n} f' \left( X_s, J_s \right) \sigma^2_s J_{ij} ds ds + \frac{1}{2} \int_0^t f' \left( X_s, J_s \right) \sigma^2_s J_{ij} ds \]

Then it is easy to see that the infinitesimal generator of the process \( (X_t, J_t) \), \( t \geq 0 \) satisfies

\[
(Af)(x,i) = \sum_{j \neq i} v_{ij} f'(x,j) + f'(x,i) \frac{1}{2} \sigma^2 f' \left( x, i \right),
\]

where \( f(x,i) \) and \( f'(x,i) \) are the first and second order partial derivatives at \( x \) and the domain of \( A \) includes the set \( C \).

**Proposition 4.1.** Let \( (X_t, J_t) \) be the stationary distribution of process \( (X_t, J_t) \). Then the stationary densities \( q_i(x) \) are the solutions of the following equation

\[
A(x) q(x) + B(x) q^2(x) + C(x) q(x) + V^T q(x) = 0,
\]

satisfying the following conditions

\[
pq(a^-) = (1 - p) a(a+) \quad \text{or} \quad pq(a^-) = - a(a+)
\]

\[
\int_{-\infty}^a q(x) dx = \pi^i,
\]

\[
B(a)q(a+) - Cq(a-) + Aq(a+ - q(a-)) = 0,
\]

where \( V^T \) is the transpose of \( V \) and

\[
A = \text{diag} \left( \frac{1}{2} \sigma^2_1, \ldots, \frac{1}{2} \sigma^2_N \right),
\]

\[
B(x) = \text{diag} \left( \gamma_1 x, \ldots, \gamma_N x \right),
\]

\[
C = \text{diag} \left( \gamma'_1, \ldots, \gamma'_N \right),
\]

\[
q(x) = \left[ q_1(x), \ldots, q_N(x) \right]^T,
\]

with the definition

\[
(a_1, a_2, \ldots, a_N) = \begin{cases}
  0 & 0 0 0 \\
  a_1 & 0 0 0 \\
  0 0 0 & a_2 \\
  0 0 0 0 & a_3 \\
  & \cdots \\
  & 0 0 0 0 \end{cases}.
\]

Generally speaking, it is difficult to calculate the closed form of (8) and (9). While in some special cases, the closed solutions of stationary densities can be figured out.

**Proof:** From exercise 57, P.394 in [15], we know that a probability density \( q_i(x) \) is a stationary density for \( X_t \) if and only if the following equation is satisfied

\[
\sum_{i=1}^N \int_{x_i} E f(x, j) q_i(x) dx = \int_{x_i} E f(x, j) q_i(x) dx + \sum_{j \neq i} v_{ij} \int_{x_j} E f(x, j) q_i(x) dx,
\]

\[
= \int_{x_i} E f(x, j) q_i(x) dx + \sum_{j \neq i} v_{ij} E f(x, j) q_i(x) dx + \frac{1}{2} \int_{x_i} f(x, j) \sigma^2 \sigma_{ij} dx + \frac{1}{2} \int_{x_j} f(x, j) \sigma^2 \sigma_{ij} dx + \frac{1}{2} \int_{x_i} f(x, j) \sigma^2 \sigma_{ij} dx + \frac{1}{2} \int_{x_j} f(x, j) \sigma^2 \sigma_{ij} dx + \sum_{j \neq i} v_{ij} E f(x, j, i).
\]

5. Special Cases

**Example.** Set \( N = 2, a = 0 \) and the generator of the Markov chain \( J_t \) to be

\[
Q = \begin{pmatrix}
-w & w \\
-v & -v
\end{pmatrix},
\]

where \( w, v > 0 \). From (7), we obtain \( w\pi_1 = v\pi_2 \) and \( \pi_1 = \frac{v}{w+v} \). We also assume \( \sigma_1 = \sqrt{\gamma} \), for \( i = 1, 2 \); with these assumptions, the closed form of stationary densities for \( (X_t, J_t) \) can be obtained:

\[
q_1(x) = \frac{\sqrt{\gamma}}{\sqrt{\gamma}} \pi_1 e^{-\gamma x}, \quad x < 0,
\]

\[
q_2(x) = \frac{\sqrt{\gamma}}{\sqrt{\gamma}} \pi_2 e^{-\gamma x}, \quad x < 0,
\]

\[
q_1(x) = \frac{2p}{\sqrt{\gamma}} \pi_1 e^{-\gamma x}, \quad x < 0,
\]

\[
q_2(x) = \frac{2p}{\sqrt{\gamma}} \pi_2 e^{-\gamma x}, \quad x \geq 0,
\]

**Proof.** We have done above, from Proposition 4.1, the
stationary densities $q_1(x)$ and $q_2(x)$ should satisfy the following equation group

\[
\begin{align*}
\frac{1}{2} \gamma^x_2 q_1(x) + \gamma^x_2 q_2(x) + \gamma^x_1 q_1(x) - w_q(x) + v_q_2(x) &= 0, \\
\frac{1}{2} \gamma^x_2 q_1(x) + \gamma^x_2 q_2(x) + \gamma^x_1 q_2(x) - w_q(x) + v_q_2(x) &= 0,
\end{align*}
\]

(14)

and the following conditions should be satisfied

\[
\begin{align*}
q_1(0) &= q_2(0) = 0, \\
w_q(a) &= (1-w)q_1(a)+wq_2(a) = (1-w)q_2(a+), \\
\int_{a^-} q_1(x) dx &= \pi_1, \\
\int_{a^-} q_2(x) dx &= \pi_2, \\
\gamma^x_2 q_1(a+)-q_2(a-)+\frac{1}{2} \gamma^x_2 (q_1(a+)+q_2(a-)) &= 0, \\
\gamma^x_2 q_2(a)-q_2(a-)+\frac{1}{2} \gamma^x_2 (q_2(a+)-q_2(a-)) &= 0.
\end{align*}
\]

Adding the two equations in (14), we obtain

\[
\frac{1}{2} (\gamma^x_2 q_1(x) + \gamma^x_2 q_2(x) + x(\gamma^x_1 - \gamma^x_2) q_1(x) + \gamma^x_1 q_2(x) + \gamma^x_1 q_1(x)) = 0.
\]

Assume that $h(x) = \gamma^x_1 q_1(x) + \gamma^x_2 q_2(x)$, then $h(x)$ should satisfy the following equation

\[
\frac{1}{2} h''(x) + xh(x) + h(x) = 0.
\]

Through simple calculation, the general solution of above equation should be $h(x) = ce^{-x^2}$ with $c$ is a constant. Because of the conditions for $q_1(x)$ and $q_2(x)$, $h(x)$ must satisfy the following conditions

\[
\begin{align*}
h(0) &= \gamma^x_1 q_1(0) + \gamma^x_2 q_2(0) = 0, \\
h(a) &= \gamma^x_1 q_1(a+)+\gamma^x_1 q_2(a-)+\frac{1}{\alpha} [\gamma^x_1 q_1(a+)+\gamma^x_2 q_2(a-)] = \frac{1-\alpha}{\alpha} h(a), \\
\int_{a^-} h(x) dx &= \int_{a^-} [\gamma^x_1 q_1(x)+\gamma^x_2 q_2(x)] dx = \pi_1, \pi_2.
\end{align*}
\]

Combining the above conditions and the general solution of $h(x)$, we get

\[
h(x) = \gamma^x_1 q_1(x) + \gamma^x_2 q_2(x),
\]

\[
= \begin{cases} 
\frac{(1-p)^x}{\sqrt{\pi}} [\pi_1 \gamma_1^x + \pi_2 \gamma_2^x] e^{-x^2}, & x < 0, \\
\frac{2p}{\sqrt{\pi}} [\pi_1 \gamma_1^x + \pi_2 \gamma_2^x] e^{-x^2}, & x \geq 0,
\end{cases}
\]

and the solutions of $q_1(x)$ and $q_2(x)$ are exhibited in (12) and (13).
