(Dated: February 2, 2008)

The big trip can be describe with the help of the Wheeler-DeWitt wave equation \( \hat{H} \psi(w, a) = 0 \). The probability to find the universe after big trip in the state with \( w = w_0 \) will be maximal if \( \partial \psi(w, a) / \partial w |_{w=w_0} = 0 \) for any values of the scale factor \( a \). It is shown that this will be the case if and only if \( w_0 = -1/3 \). This fact allows one to suggest that vast majority of universes in multiverse must be in this state after their big trips.

I. INTRODUCTION

The cosmology nowadays is amazingly abundant with a new startling solutions. Some of the most recent ones are the models with the "Phantom fields" which result in the violation of the weak energy condition (WEC) \( \rho > 0 \), \( \rho + p/c^2 > 0 \) [1, 2], where \( \rho \) is the fluid density and \( p \) is the pressure. Such phantom fields, as follows from their quantum theory [3], should inevitably be described by the scalar field with the negative kinetic term. The through investigations shows that such fields are apparently could not be considered as a fundamental objects. However, it is possible that the Lagrangians with the negative kinetic terms will appear as some kind of effective models, as it happens in some models of supergravity [4], in the gravity theories with highest derivatives [5] and in field string theory [6], for example in model which is close to the fermion NSR-string with regard for (GSO-)-sector (see also [7]). Finally, the "phantom energy" in the brane theory was considered in [8], [9].

Remark 1. Despite of all said above, We can not be assured that phantom energy is only effective model. The reason is the existence of "the crossing of the phantom divide line". There are exact solutions of Einstein equations which describes this crossing. Moreover, this crossing is smooth and one can conclude that smooth (de)-phantomization is the sufficiently general property of Einstein equations. This effect was discover in [10], [11] and it was interpreted in [12]. Therefore if we were (following [12]) guided by a belief that Einstein equations are more fundamental then the concrete form of the Lagrangian for other fields then one can conclude that "the crossing of the phantom divide line" is possible and this is the new fundamental property of gravitation.

The particular interest to models with the phantom fields is caused by their prediction of so-called "Cosmic Doomsday" alias big rip [1] (see also [13]). In case of the phantom energy we have \( w = p/(c^2 \rho) = -1 - \epsilon \) with \( \epsilon > 0 \). Integration of the Einstein-Friedmann equation for the flat universe results in

\[
\begin{align*}
\rho(t) &= \rho_0 \left( \frac{a(t)}{a_0} \right)^{3\epsilon} = \rho_0 \left( 1 - \xi t \right)^2, \\
\end{align*}
\]

where \( \xi = \sqrt{6\pi G \epsilon \rho_0} \). We choose \( t = 0 \) as the present time, \( a_0 \sim 10^{28} \) cm and \( \rho_0 \) to be the present values of the scale factor and the density. There, if \( t = t_* = 1/\xi \), we automatically get the big rip.

Remark 2. There are few ways to escape of future big rip singularity: (i) to consider phantom energy just as some effective models (see above); (ii) to use quantum effects to delay the singularity [14]; (iii) to use new time variable such that the big rip singularity will be point at infinity \( (t \to \infty) \) [15]; (iv) to avoid big rip via another cosmological "Big"; big trip (see below).

In [16] Pedro F. González-Díaz had shown that phantom energy can results in achronal cosmic future where the wormholes become infinite before the occurrence of the big rip singularity. To show this lets consider the wormhole with the throat radius \( b_0 = 10^{-33} \) cm (Planck scale). It was shown in [16] that if \( p = -\left(1 + \epsilon\right)c^2 \rho \) is a fluid’s equation of state, then

\[
\begin{align*}
\dot{b}(t) &= 2\pi^2 \epsilon GD \rho(t) b^2(t), \\
\end{align*}
\]

where \( b(t) \) is the throat radius of a Morris-Thorne wormhole and \( D \) is dimensionless quantity. According to [16] we can choose \( D \sim 4 \) (see also [17]). The equation (2) describes the changing of the \( b(t) \) with regard to the phantom energy’s accretion. Integration of the (2) gets us

\[
\begin{align*}
\frac{1}{b(t)} &= \frac{1}{b_0} - \frac{2\pi^2 \epsilon \rho_0 GD t}{c(1 - \xi t)}. \\
\end{align*}
\]

Therefore at

\[
\begin{align*}
\dot{t} &= \frac{c}{\epsilon \sqrt{6\pi G \rho_0 + 2\pi^2 \rho_0 GD}} \quad (4)
\end{align*}
\]

we get \( \dot{t} = \infty \). As we can see \( \dot{t} < t_* \), and therefore this universe indeed will be achronal before the occurrence of
the big rip. In accord to [10], at $t > \tilde{t}$, while in process of the phantom energy’s accretion, the wormhole becomes an Einstein-Rosen bridge which can, in principle, be used to escape from the big rip. In accord to [16], at

$$N = \int_{\partial M} d^{3}x \sqrt{-h} \text{Tr} \hat{\mathcal{K}},$$

(7)

where $\hat{R}$ is the generalized Ricci curvature scalar (6), $K$ is the conventional expression for the extrinsic curvature, $g = \det g_{\mu\nu}$, $h$ is the determinant of the general threemetric on the given hypersurface at the boundary $\partial M$. Since $\sqrt{-g} \sim Na^3$ then one can integrate (7) over spatial variables and substitute $t \rightarrow i\tau$ (with $8\pi G/3 = 1$) to reduce (7) to Euclidean action:

$$I = \int d\tau N \left[ 6a a'^3 - 3aF(a, a', w, w') + 6a^3w \rho \right],$$

(8)

where

$$F(a, a', w, w') = 3(1 + w)a'^3 - a^3 \left( \frac{\partial p}{\partial a'} + \frac{\partial p}{\partial w'} \right),$$

and $\tau = d/d\tau$. In the gauge where $N = 1$ we have the Hamiltonian constraint

$$H = \frac{\delta I}{\delta N} - (w + 1)a^3\rho = 0.$$  

(9)

The next step to the Wheeler-DeWitt equation is to define the momenta conjugate to $a$ ($\pi_a$) and $w$ ($\pi_w$) and redefine the (classical) Hamiltonian (9) via $\pi_a$, $\pi_w$, $a$ and $w$. At last one must introduce the following quantum operators:

$$\hat{\pi}_a = -i \frac{\partial}{\partial a}, \quad \hat{\pi}_w = -i \frac{\partial}{\partial w},$$

and

$$\hat{E} = \hat{\pi}_a \pi_a + \hat{\pi}_w \pi_w.$$
which allows one to obtain the the Wheeler-DeWitt equation (WDE) $H\psi = 0$. Thus we have

$$4 \left( \frac{\partial \rho}{\partial a} + 2\rho \right) \frac{\partial^2 \psi}{\partial w^2} - 4a \frac{\partial \rho}{\partial w} \frac{\partial^2 \psi}{\partial a \partial w} = 3 \left( \frac{\partial \rho}{\partial w} \right)^2 a^6(1 + 3w)\psi,$$

(10)

with $\psi = \psi(a, w)$.

The WDE (10) is differ from the WDE which was obtained in [20] because we didn’t use the condition $\ddot{w} = 0$ which allows one to simplify the actions (17), (18) using the rejection of corresponding surface terms. As we shall see, the Eq. (10) result in new ”Big” in cosmology - the ”Big Meeting”.

First at all, let consider the case $w = -1/3$. In this case the right side of the (10) will be zero. Moreover, if $w = -1/3$ then $\rho = \rho(a, w = -1/3) \sim a^{-2}$ therefore

$$\frac{\partial \rho}{\partial a} + 2\rho = 0,$$

and the WDE (10) is reduced to

$$\frac{\log a}{a} \frac{\partial^2 \psi}{\partial a \partial w} = 0.$$  

(11)

Using power series

$$\psi(a, w) = \psi(a, -1/3) + \sum_{n=1}^{\infty} \frac{1}{n!} c_n(a) \left( w + \frac{1}{3} \right)^n,$$

and (11) we get $dc_1(a)/da = 0$ thus

$$\frac{\partial \psi(a, w)}{\partial w} |_{w=-1/3} = c_1 = \text{const.}$$  

(12)

On the other hand, the equation (11) is invariant with respect to transformation

$$\psi(a, w) \rightarrow \psi(a, w) - f_1(a) - f_2(w),$$

(13)

for arbitrary function $f_{1,2}$. Substituting (13) into the (12) and choosing $df_1(w)/dw = c_1$ at $w = -1/3$ we get without loss of generality

$$\frac{\partial \psi(a, w)}{\partial w} |_{w=-1/3} = 0.$$  

(14)

Therefore, in the case of general position, for any fixed $a$ the function $\psi(a, w) = \Phi_2(w)$ has the extremum at $w = -1/3$. Since the function $\psi$ must be normalizable one, the point $w = -1/3$ must be the point of maximum. In other words, the probability distribution $|\psi(a, w)|^2$ for any given value of the scale factor has the peak at $w = -1/3$.

One can prove this fact for the general position. Let consider the equation (11). We’d like to consider the solutions of this equation such that

$$\frac{\partial \psi(a, w)}{\partial w} |_{w=w_0} = 0,$$

(15)

for any given $a$. Since $w_0 = \text{const}$ then $\rho(a, w_0) = \rho_0 = C^2 a^{-3({w_0}+1)} (C = \text{const})$ and

$$\frac{\partial \rho}{\partial a} = -3(w_0 + 1) \rho_0,$$

(16)

$$\frac{\partial \rho}{\partial w_0} = -3 \log a \rho_0.$$  

(17)

Besides

$$\frac{\partial^2 \psi}{\partial a \partial w} |_{w=w_0} = \frac{\partial}{\partial a} \left( \frac{\partial \psi(a, w)}{\partial w} |_{w=w_0} \right) = 0.$$  

(18)

Substituting (16), (17) and (18) into the (10) we get

$$(1 + 3w_0) \left( 4a^{-3(w_0+1)} \frac{\partial^2 \psi}{\partial w^2} + 27C^2 a^{-6w_0} \log^2 a \psi \right) = 0.$$  

(19)

Using (19) one can conclude that $w_0 = -1/3$ or the following equation must be hold

$$\frac{\partial^2 \psi}{\partial w^2} = \frac{27C^2}{4} a^{-3(w_0-1)} \log^2 a \psi.$$  

(20)

The general solution of the (20) has the form

$$\psi(w_0, a) = c_1 J_0(z) + c_2 Y_0(z),$$

(21)

where $c_{1,2}$ are arbitrary constants, $z = \sqrt{3} C a^{3(1-w_0)/2}$, $J_0$ and $Y_0$ are the Bessel functions of the first and second kind. This function must be normalizable one:

$$\int_0^{\infty} da |\psi(w_0, a)|^2 < +\infty,$$

(22)

so one need to choose $c_2 = 0$ ($Y_0(z) \sim 2 \log z / \pi$ at $z \rightarrow 0$) or if $c_2 \neq 0$ then we get the divergence in the (22) for $a \rightarrow 0$. Substituting (21) into the (18) one get

$$\frac{\partial \psi}{\partial w_0} = \frac{3\sqrt{3} C}{2} a^{3(1-w_0)/2} \log a J_1 \left( \sqrt{3} C a^{3(1-w_0)/2} \right) = 0,$$

(23)

which will be the case for arbitrary $a$ if and only if $w_0 = 1$ and $C$ is the solution of the equation

$$C J_1(\sqrt{3} C) = 0.$$  

But if $w_0 = 1$ then the wave function $\psi = \text{const}$ (and the same will be the case for the density $\rho$ (see (10))). Such wave function will be non-normalizable one, thus, there is only one way to comply with (15) in framework of normalizable wave function of the universe: to put $w_0 = -1/3$. The end of the proof.

One can ask about possibility of existence of another peaks $M_\star = (a_\star, w_\star)$ of solutions of the (10), such that

$$\frac{\partial \psi}{\partial a} |_{M_\star} = \frac{\partial \psi}{\partial w} |_{M_\star} = 0.$$  

and
\[ \Delta = \left[ \frac{\partial^2 \psi}{\partial w^2} \frac{\partial^2 \psi}{\partial a^2} - \left( \frac{\partial^2 \psi}{\partial w \partial a} \right)^2 \right]_{M_*} > 0. \] (23)

As we shall see, it is possible to neglect these extremum. In fact, one need to use the dimensionless variables in expressions like \( \log a \). Keeping in mind that our universe was born via big trip from another, a paternal universe with the value of its scale factor \( L \), one must replace \( \log a \rightarrow \log(a/L) \). On the other hand, one can expect that the initial value of the scale factor \( a_i \) of the universe after the big trip will be \( a_i \approx L \). Let consider such universe with \( w = \text{const} \). If we’d like to estimate the probability to find this universe just after the big trip (that is with \( a_i \approx L \approx a_* \)) then one must use the WDE (10) which reduce to the simple form
\[ -4a^{-3(w+1)}(3w+1) \frac{\partial^2 \psi}{\partial w \partial a} |_{M_*} = 0. \]

If \( w \neq -1/3 \) then (see (23))
\[ \Delta = - \left( \frac{\partial^2 \psi}{\partial w \partial a} \right)^2 |_{M_*} < 0, \]
and we have not extremum at all.

### III. CONCLUSION

Therefore, as we seen, in the case of general position the solution of (10) and the probability distribution has the peaks at \( w = -1/3 \) for any \( a \) if we consider universes just after big trip. This fact result in new possible "Big" in modern cosmology which can be called as "Big Meeting". It means that vast majority of universes in multiverse must be in the state with \( w = -1/3 \) just after their big trips.
