STUDIES IN ADDITIVE NUMBER THEORY BY CIRCLES OF PARTITION

T. AGAMA AND B. GENSEL

Abstract. In this paper we introduce and develop the circle embedding method. This method hinges essentially on a Combinatorial structure which we choose to call circles of partition. We provide applications in the context of problems relating to deciding on the feasibility of partitioning numbers into certain class of integers. In particular, our method allows us to partition any sufficiently large number \( n \in \mathbb{N} \) into any set \( \mathbb{H} \) with natural density greater than \( \frac{1}{2} \). This possibility could herald an unprecedented progress on class of problems of similar flavour. The paper finishes by giving an asymptotic proof of the binary Goldbach and the Lemoine conjecture as application of the developed method.

1. Introduction and Preliminary Results

In this section we recall some well-known results that will partly be needed in this paper and to some for the sake of their beauty and insurmountable importance in the field. We find some results concerning the distribution of some sequences in arithmetic progression useful in the current paper. First we state the celebrated Szemeredi theorem concerning arithmetic progression. The theorem has both infinite and finite version, but we have considered appropriate to state the finite version.

**Theorem 1.1** (Szemeredi). \( \forall \varepsilon > 0 \) and \( \forall k \in \mathbb{N} \) there exists an \( n \in \mathbb{N} \) such that if \( A \subset \mathbb{N} \) satisfies \( |A| \geq \varepsilon n \), then \( A \) contains an arithmetic progression of length \( k \).

The well-known Green-Tao theorem \([4]\) provides an extension in this direction as

**Theorem 1.2** (Green-Tao). Let \( \pi(n) \) denotes the number of primes no more than \( n \). If \( A \subset \mathbb{P} \) the set of all prime numbers such that

\[
\limsup_{n \to \infty} \frac{|A \cap \mathbb{N}_n|}{\pi(n)} > 0
\]

then \( A \) contains infinitely many arithmetic progressions of length \( k \) for any \( k > 0 \).

In this paper, motivated in part by the binary Goldbach conjecture and its variants, we develop a method which we feel might be a valuable resource and a recipe for studying problems concerning partition of numbers in specified subsets of \( \mathbb{N} \). The method is very elementary in nature and has parallels with configurations
of points on the geometric circle.

Let us suppose that for any $n \in \mathbb{N}$ we can write $n = u + v$ where $u, v \in \mathbb{M} \subset \mathbb{N}$ then the circle embedding method associate each of this summands to points on the circle generated in a certain manner by $n > 2$ and a line joining any such associated points on the circle. This geometric correspondence turns out to useful in our development, as the results obtained in this setting are then transformed back to results concerning the partition of integers. We study various features and statistics of a Combinatorial structure in this development, which we choose to call the circle of partition.

2. The Circle of Partition

In this section we introduce the notion of the circle of partition. We study this notion in-depth and explore some potential applications in the following sequel.

**Definition 2.1.** Let $n \in \mathbb{N}$ and $\mathbb{M} \subset \mathbb{N}$. We denote with

$$C(n, \mathbb{M}) = \{ [x] \mid x, y \in \mathbb{M}, n = x + y \}$$

the Circle of Partition generated by $n$ with respect to the subset $\mathbb{M}$. We will abbreviate this in the further text as CoP. We call members of $C(n, \mathbb{M})$ as points and denote them by $[x]$. For the special case $\mathbb{M} = \mathbb{N}$ we denote the CoP shortly as $C(n)$.

**Definition 2.2.** We denote the line $L_{[x],[y]}$ joining the point $[x]$ and $[y]$ as an axis of the CoP $C(n, \mathbb{M})$ if and only if $x + y = n$. We say the axis point $[y]$ is an axis partner of the axis point $[x]$ and vice versa. We do not distinguish between $L_{[x],[y]}$ and $L_{[y],[x]}$, since it is essentially the same axis. The point $[x] \in C(n, \mathbb{M})$ such that $2x = n$ is the center of the CoP. If it exists then we call it as a degenerated axis $L_{[x]}$ in comparison to the real axes $L_{[x],[y]}$. The line joining any two arbitrary point which are not axes partners on the CoP will be referred to as a chord of the CoP. The length of the chord $L_{[x],[y]}$ joining the points $[x], [y] \in C(n, \mathbb{M})$, denoted as $\Gamma([x],[y])$ is given by

$$\Gamma([x],[y]) = |x - y|.$$  

It is important to point out that the median of the weights of each co-axis point coincides with the center of the underlying CoP if it exists. That is to say, given all the real axes of the CoP $C(n, \mathbb{M})$ as

$$L_{[u_1],[v_1]}, L_{[u_2],[v_2]}, \ldots, L_{[u_k],[v_k]}$$

then the following relations hold

$$\frac{u_1 + v_1}{2} = \frac{u_2 + v_2}{2} = \cdots = \frac{u_k + v_k}{2} = \frac{n}{2}$$

which is equivalent to the conditions for any of the pair of real axes $L_{[u_i],[v_i]}$, $L_{[u_j],[v_j]}$ for $1 \leq i, j \leq k$

$$\Gamma([u_i],[u_j]) = \Gamma([v_i],[v_j])$$

and

$$\Gamma([v_j],[u_i]) = \Gamma([u_j],[v_i]).$$
Definition 2.3. Let $M \subseteq \mathbb{N}$ and $C(n, M)$ and $C(m, M)$ be two distinct CoPs for which holds

$$C(n, M) \subset C(m, M) \quad (2.1)$$

or

$$C(n, M) \supset C(m, M). \quad (2.2)$$

Then we say the CoPs admit embedding. We say the CoPs admit aligned embedding if and only if with $(2.1)$ holds $n < m$ and with $(2.2)$ holds if and only if $n = m$. We say the CoPs admit reverse aligned embedding if and only if with $(2.1)$ holds $n > m$ and with $(2.2)$.

Notations. We let $N_n = \{m \in \mathbb{N} \mid m \leq n\}$ be the sequence of the first $n$ natural numbers. Further we will denote $[|x|] := x$ as the weight of the point $[x]$ and correspondingly the weight set of points in the CoP $C(n, M)$ as $||C(n, M)||$.

The above language in many ways could be seen as a criterion determining the plausibility of carrying out a partition in a specified set. Indeed this feasibility is trivial if we take the set $M$ to be the set of natural numbers $\mathbb{N}$. The situation becomes harder if we take the set $M$ to be a special subset of natural numbers $\mathbb{N}$, as the corresponding CoP $C(n, M)$ may not always be non-empty for all $n \in \mathbb{N}$. One archetype of problems of this flavour is the binary Goldbach conjecture, when we take the base set $M$ to be the set of all prime numbers $\mathbb{P}$. One could imagine the same sort of difficulty if we extend our base set to other special subsets of the natural numbers. As such we start by developing the theory assuming the base set of natural numbers $\mathbb{N}$ and latter extend it to other base sets $M$ equipped with certain important and subtle properties.

Remark 2.4. It is important to notice that a typical CoP need not have a center. In the case of an absence of a center then we say the circle has a deleted center. However all CoPs $C(n)$ with even generators have a center. It is easy to see that the CoP $C(n)$ contains all points whose weights are positive integers from 1 to $n - 1$ inclusive:

$$C(n) = \{[x] \mid x \in \mathbb{N}, x < n\}.$$

Therefore the CoP $C(n)$ has $\left\lfloor \frac{n-1}{2} \right\rfloor$ different real axes.

Proposition 2.5. Each axis is uniquely determined by points $[x] \in C(n, M)$.

Proof. A degenerated axis is determined by the center of the CoP. And this is unique if it exists.

Let $L_{[x],[y]}$ be a real axis of the CoP $C(n, M)$. Suppose as well that $L_{[x],[z]}$ is also a real axis with $z \neq y$. Then it follows by Definition 2.3 that we must have $n = x + y = x + z$ and therefore $y = z$. This cannot be and the claim follows immediately. \qed

Corollary 2.6. Each point of a CoP $C(n, M)$ excluding an existing center has exactly one real axis partner.
Proof. Let \([x] \in \mathcal{C}(n, M)\) be a point without a real axis partner. Then holds for every point \([y] \neq [x]\)
\[\|x\| + \|[y]\| \neq n.\]
This contradiction to the Definition 12.2. Due to Proposition 2.5 the case of more than one axis partners is impossible. This completes the proof. \(\square\)

**Corollary 2.7.** The weights of the points of
\[\mathcal{C}(n, M) = \{[x_1], [x_2], \ldots, [x_k]\}\]
are strictly totally ordered.

Proof. W.l.o.g. we assume that
\[x_1 = \min (x \mid [x] \in \mathcal{C}(n, M))\] and
\[x_k = \max (x \mid [x] \in \mathcal{C}(n, M)).\] (2.3) (2.4)
At first we assume that \(x_1 + x_k < n\). Then there is a weight \(x_i\) with
\[x_1 < x_i < x_k\] and \(n = x_1 + x_i\).
Because \(x_i < x_k\) we get
\[n = x_1 + x_i < x_1 + x_k.\]
This contradicts the assumption. Now we assume that \(x_1 + x_k > n\). Then there is a weight \(x_i\) with
\[x_1 < x_i < x_k\] and \(n = x_i + x_k.\)
Because \(x_i > x_1\) we get
\[n = x_i + x_k > x_1 + x_k.\]
This also contradicts the assumption. Therefore remains \(x_1 + x_k = n\). Because of (2.3) and (2.4) holds
\[x_1 < x_2 < x_{k-1} < x_k.\]
Now we remove \(x_1\) and \(x_k\) out of the consideration and repeat the procedure above with \(x_2\) and \(x_{k-1}\) and obtain \(x_2 + x_{k-1} = n\) and
\[x_1 < x_2 < x_3 < x_{k-2} < x_{k-1} < x_k.\]
By repeating this procedure for \(x_i\) and \(x_{k+1-i}\) for \(3 \leq i \leq \left\lfloor \frac{k}{2} \right\rfloor\) we get finally
\[x_1 < x_2 < x_3 < x_4 < \ldots < x_{k-3} < x_{k-2} < x_{k-1} < x_k.\] \(\square\)

**Proposition 2.8.** Let \(\mathcal{C}(n, M)\) and \(\mathcal{C}(m, M)\) be two distinct CoPs admitting aligned embedding. Then holds
\[\mathcal{C}(n, M) \cup \mathcal{C}(m, M) \subset \mathcal{C}(n + m, M).\]

Proof. W.l.o.g. we assume \(\mathcal{C}(n, M) \subset \mathcal{C}(m, M)\). Then holds
\[\mathcal{C}(n, M) \cup \mathcal{C}(m, M) = \mathcal{C}(m, M)\]
and because of admitting aligned embedding
\[\subset \mathcal{C}(n + m, M)\] due to \(m < n + m.\) \(\square\)
Theorem 2.9. Let $n \in \mathbb{N}$ and $C(n)$ be a CoP generated by $n$. Then $C(n)$ admits aligned embedding.

Proof. W.l.o.g. we have to prove for two distinct CoPs $C(n) \subset C(m)$ if and only if $n < m \mid n, m \in \mathbb{N}$.

First let $n < m$. Then follows that $C(n) = \{x \in \mathbb{N} \mid x < n\} \subset \{x \in \mathbb{N} \mid x < m\} = C(m)$.

Conversely we suppose $C(n) \subset C(m)$. Then it follows that $\{x \in \mathbb{N} \mid x < n\} \subset \{x \in \mathbb{N} \mid x < m\}$ and it holds $n < m$. □

Now we will see that Theorem 2.9 is always valid for some special subsets $\mathbb{M}$ instead of $\mathbb{N}$, the subsets containing arithmetic progressions. Let be $M_{a,d} \subset \mathbb{N}$ with $M_{a,d} := \{x \in \mathbb{N} \mid x \equiv a \pmod{d}, d \in \mathbb{N}\}$ (2.5)

and

$C(n, M_{a,d}) = \{x+y = n \land x, y \in M_{a,d}, n \in M_{2a,d}\}
= \{x \mid x \in M_{a,d} \land x \leq n-a\}.$

For $x < y \in M_{a,d}$ holds $y-x \equiv 0 \pmod{d}$. On the other hand holds $x+y \equiv 2a \pmod{d}$, so that $C(n, M_{a,d}) = \emptyset$ for $n \not\in M_{2a,d}$.

Theorem 2.10. Let $n \in M_{2a,d}$ and $C(n, M_{a,d})$ be a CoP generated by $n$. Then the CoP admits aligned embedding an increment $d$.

Proof. W.l.o.g. we have to prove $C(n, M_{a,d}) \subset C(m, M_{a,d})$ if and only if $n < m$.

At first let be $n < m$. Since $n, m \in M_{2a,d}$ holds $m - n = k \cdot d$ has an increment $d$. Further holds

$$||C(n, M_{a,d})|| = \{k \in M_{a,d} \mid k \leq n-a\}$$
and because of $n < m$
$$\subset \{k \in M_{a,d} \mid k \leq m-a\}$$
$$= ||C(m, M_{a,d})||.$$ 

On the other hand let be $C(n, M_{a,d}) \subset C(m, M_{a,d})$. Then holds

$$||C(n, M_{a,d})|| = \{k \in M_{a,d} \mid k \leq n-a\}$$
$$\subset ||C(m, M_{a,d})||$$
$$= \{k \in M_{a,d} \mid k \leq m-a\}$$
and therefore must be
$$n < m.$$ □
Corollary 2.11. Let $C(n, M)$ and $C(m, M)$ be two distinct CoPs admit align embedding. Then holds

$$C(n, M) \supset C(m, M) \text{ if and only if } n > m.$$ 

Corollary 2.12. Because of Proposition 2.8 and Theorem 2.10 holds for two distinct CoPs $C(n, M_{a,d})$ and $C(m, M_{a,d})$

$$C(n, M_{a,d}) \cup C(m, M_{a,d}) \subset C(n + m - 2a, M_{a,d}).$$

Remark 2.13. CoPs $C(n, P)$ with the set of all prime numbers as base set are important examples for CoPs not admitting embedding. The following example demonstrates this scenario.

$$C(20, P) = \{3, 7, 13, 17\} \text{ but } C(22, P) = \{3, 5, 11, 17, 19\}.$$ 

Proposition 2.14. Let $M \subseteq \mathbb{N}$ and $C(n, M) \subset C(m, M)$ two CoPs with a common base set $M$ and $w_o$ and $z_o$ the weights of the median points of $C(n, M)$ resp. $C(m, M)$. If $w_o < z_o$ then the CoPs admit aligned embedding, if $w_o > z_o$ the CoPs admit reverse aligned embedding.

Proof. Let

$$u_o := \min(u \in \|C(n, M)\|) \text{ and } x_o := \min(x \in \|C(m, M)\|) \text{ be the least weights of the CoPs and }$$

$$v_o := \max(v \in \|C(n, M)\|) \text{ and } y_o := \max(y \in \|C(m, M)\|) \text{ the greatest weights of the CoPs.}$$

Because the CoPs are strictly totally ordered the minimal and the maximal points are unique. Then

$$w_o := \frac{u_o + v_o}{2} = \frac{n}{2} \text{ and } z_o := \frac{x_o + y_o}{2} = \frac{m}{2}$$

are the weights of the median points of the CoPs and we can distinguish three cases

A.) $w_o < z_o$,  
B.) $w_o = z_o$,  
C.) $w_o > z_o$.

Because of $C(n, M) \subset C(m, M)$ all points of $C(n, M)$ must be also points of $C(m, M)$. Therefore must be

$$x_o \leq u_o < v_o \leq y_o.$$ 

Now we consider the case A.):

From $w_o < z_o$ follows immediately $n < m$. That means $C(n, M)$ admits aligned embedding. This includes the case of a common first point ($x_o = u_o$) of both CoPs. The opposite we get in case C.):

From $w_o > z_o$ follows immediately $n > m$. That means $C(n, M)$ admits reverse aligned embedding. This includes the case of a common last point ($v_o = y_o$) of both CoPs.

In case B.) we would obtain $n = m$. Because of $C(n, M) \subset C(m, M)$ there must be at least one real axis $L_{[t], [\bar{t}]} \in C(m, M)$ which is not a real axis of $C(n, M)$. But this is because of $n = m$ impossible. Therefore case B.) don’t occur. \[\square\]
Example 2.15. As an example for reverse aligned embedding we consider the following CoPs
\[ C(36, \mathbb{P}) = \{5, 7, 13, 17, 19, 23, 29, 31\} \quad \text{and} \quad C(38, \mathbb{P}) = \{7, 19, 31\}. \]
We see that \( C(38, \mathbb{P}) \subset C(36, \mathbb{P}) \) but \( 38 > 36 \).

Notation. Let us denote the assignment of an axis \( L_{[x],[y]} \) resp. \( L_{[x]} \) to a CoP \( C(n, M) \) as
\[ L_{[x],[y]} \in C(n, M) \] which means \( [x],[y] \in C(n, M) \) and \( x + y = n \) resp.
\[ L_{[x]} \in C(n, M) \] which means \( [x] \in C(n, M) \) and \( 2x = n \)
and the number of real axes of a CoP as
\[ \nu(n, M) := \#\{L_{[x],[y]} \in C(n, M) \mid x < y\}. \]
Obviously holds
\[ \nu(n, M) = \left\lfloor \frac{k}{2} \right\rfloor, \quad \text{if} \quad |C(n, M)| = k. \]

Proposition 2.16. Let \( M \subset \mathbb{N} \) and \( C(n, M) \) be a CoP admitting aligned embedding. Then \( \nu(n, M) \) is a non-decreasing function for all \( n \) such that \( C(n, M) \) is not empty.

Proof. Since the CoP \( C(n, M) \) admits aligned embedding it holds w.l.o.g.
\[ C(n, M) \subset C(m, M) \text{ for } n < m \] and hence
\[ |C(n, M)| < |C(m, M)| \] and therefore
\[ \nu(n, M) < \nu(m, M). \]
\[ \square \]

Let be
\[ \mathbb{N}^* = \{n \in \mathbb{N} \mid n \equiv \pm 1(\text{mod } 6)\}. \] (2.6)
Then holds that the set \( \mathbb{P}^* \) of all primes \( \geq 5 \) is covered by \( \mathbb{N}^* \).

Proposition 2.17. The CoP \( C(n, \mathbb{N}^*) \) admits aligned embedding with an increment 6 for all \( n \) such that \( n \equiv \pm 2(\text{mod } 6) \) or \( n \equiv 0(\text{mod } 6) \).

Proof. If \( n \equiv -2(\text{mod } 6) \) then must hold for the weights of all points \([x] \in C(n, \mathbb{N}^*) \) \( x \equiv -1(\text{mod } 6) \). Then all points of \( C(n, \mathbb{N}^*) \) are points of \( C(n, M_{5,6}) \). In the other case \( n \equiv +2(\text{mod } 6) \) must be \( x \equiv +1(\text{mod } 6) \). Hence holds
\[ C(n, \mathbb{N}^*) = \begin{cases} C(n, M_{5,6}) & \text{if } n \equiv -2(\text{mod } 6) \\ C(n, M_{1,6}') & \text{if } n \equiv +2(\text{mod } 6) \end{cases} \]
where \( M_{1,6}' := M_{1,6} \setminus \{1\} \). Because of Theorem 2.11 follows the claim for \( n \equiv \pm 2(\text{mod } 6) \).

If \( n \equiv 0(\text{mod } 6) \) then it must be for every real axis \( L_{[x],[y]} \)
\[ x \text{ Mod } 6 = -y \text{ Mod } 6. \]
This means that if \( x \in M_{5,6} \) then must be \( y \in M'_{1,6} \) and reverse. W.l.o.g. we assume \( x \in M_{5,6} \) and \( y \in M'_{1,6} \) with \( x, y \in C(n, N^*) \) and \( x < y \). Then is
\[
x + 2 \in M'_{1,6} \text{ and } y - 2 \in M_{5,6} \text{ and due to } x + 2 + y - 2 = n
\]
holds \( x + 2, y - 2 \in C(n, N^*) \) with \( L_{[x+2],[y-2]} \in C(n, N^*) \)
and we have a chain of weights of \( C(n, N^*) \)
\[
x < x + 2 < y - 2 < y.
\]
Also holds
\[
L_{[x],[y-2]} \in C(n - 2, M_{5,6}) \text{ because of } x + y - 2 = n - 2 \text{ and}
\]
\[
L_{[x+2],[y]} \in C(n + 2, M'_{1,6}) \text{ due to } x + 2 + y = n + 2.
\]
Therefore to each real axis \( L_{[x],[y]} \) \( \in C(n, N^*) \) belong

a second real axis \( L_{[x+2],[y-2]} \in C(n, N^*) \) and

a real axis \( L_{[x],[y-2]} \in C(n - 2, M_{5,6}) \) and

a real axis \( L_{[x+2],[y]} \in C(n + 2, M'_{1,6}) \)
and each point of \( C(n, N^*) \) is a point of either \( C(n - 2, M_{5,6}) \) or \( C(n + 2, M'_{1,6}) \).

Now let us consider a real axis \( L_{[u],[v]} \) \( \in C(n - 2, M_{5,6}) \) with \( u < v \). Then is because of \( u + v = n - 2 \)
\[
L_{[u+2],[v]} \in C(n, N^*) \text{ because of } u + 2 + v = n \text{ and}
\]
\[
L_{[u],[v+2]} \in C(n, N^*) \text{ due to } u + v + 2 = n
\]
and we have a chain of weights of \( C(n, N^*) \)
\[
u < u + 2 < v < v + 2.
\]
And for a real axis \( L_{[w],[z]} \) \( \in C(n, M'_{1,6}) \) with \( w < z \) we have because of \( w + z = n + 2 \)
\[
L_{[w-2],[z]} \in C(n, N^*) \text{ because of } w - 2 + z = n \text{ and}
\]
\[
L_{[w],[z-2]} \in C(n, N^*) \text{ due to } w + z - 2 = n
\]
and we have a chain of weights of \( C(n, N^*) \)
\[
w - 2 < w < z - 2 < z.
\]
If we assume w.l.o.g. \( u < w \) then we have a chain of weights of \( C(n, N^*) \)
\[
u < u + 2 < w < z - 2 < z < v < v + 2.
\]
Therefore all points of \( C(n - 2, M_{5,6}) \) and \( C(n + 2, M'_{1,6}) \) belong to \( C(n, N^*) \) too and there is no point of \( C(n, N^*) \) which is not a point either of \( C(n - 2, M_{5,6}) \) or of \( C(n + 2, M'_{1,6}) \).

Since additional the CoPs \( C(n - 2, M_{5,6}) \) and \( C(n + 2, M'_{1,6}) \) are disjunct because \( M_{5,6} \) and \( M'_{1,6} \) are disjunct holds finally
\[
C(n, N^*) = C(n - 2, M_{5,6}) \cup C(n + 2, M'_{1,6}).
\]
Since \( C(n - 2, M_{5,6}) \) and \( C(n + 2, M'_{1,6}) \) due to Theorem \ref{thm:main} admit aligned embedding with an increment 6 and they are disjunct the CoP \( C(n, N^*) \) admits aligned embedding with an increment 6 too. \( \square \)
Corollary 2.18. If $n \equiv \pm 2 \pmod{6}$ then the CoP $C(n, \mathbb{N}^*)$ has a center if and only if $\frac{n}{2} \equiv \pm 1 \pmod{6}$. In the case $n \equiv 0 \pmod{6}$ the CoP $C(n, \mathbb{N}^*)$ has no center because all weights $x$ of it are $\equiv \pm 1 \pmod{6}$ and therefore $2x \equiv \pm 2 \pmod{6} \neq 0 \pmod{6}$.

Corollary 2.19. Because of $\mathbb{P}^* \subset \mathbb{N}^*$ the CoP $C(n, \mathbb{P}^*)$ has a center if and only if $\frac{n}{2}$ is a prime. In the case $n \equiv 0 \pmod{6}$ there is no center in $C(n, \mathbb{P}^*)$ with the same justification like in Corollary 2.18.

Theorem 2.20 (Fundamental). Let $n, r \in \mathbb{N}$, $M \subseteq \mathbb{N}$ and $C(n, M)$ be a nonempty CoP with an axis $L_{[x],[n-x]} \in C(n, M)$ \footnote{The axis can also be a degenerated axis with $x = n - x = \frac{n}{2}$ if it exists.}. If holds $x + r \in M$ then $C(n + r, M)$ is a nonempty CoP too.

Proof. Since $L_{[x],[n-x]} \in C(n, M)$, $x$ and $n - x$ are members of $M$. And due to the premise also $x + r \in M$. Then holds

$$n + r - (x + r) = n - x \in M.$$ 

Ergo there is an axis $L_{[x+r],[n+r-(x+r)]} \in C(n + r, M)$ and $C(n + r, M)$ is nonempty. □

Corollary 2.21. Let the requirements of Theorem 2.20 be fulfilled. If the base set $M$ is an infinite set and there exists a nonempty CoP $C(n, M)$ then there exist infinitely many positive integers $n > n_o$ with nonempty CoPs $C(n, M)$.

Proof. Let $L_{[x],[n-x]}$ be an axis of $C(n, M)$. Then is due to Theorem 2.20 also $C(n + r_1, M)$ with $r_1 > 0$ nonempty if $x + r_1 \in M$. From this CoP we can continue this process with $r_2 > 0$ to the nonempty CoP $C(n_o + r_1 + r_2, M)$ with such $r_2$ that $n_o + r_1 + r_2 \in M$. Since the base set is an infinite set this process can be repeated infinitely many. □

3. Rotation and Dilation of Circles of Partition

In this section we introduce the notion of the Rotation and Dilation of CoPs produced by a given generator. We launch the following formal terminology.

Definition 3.1. Let $\mathbb{M} \subseteq \mathbb{N}$ with $n \in \mathbb{N}$ and $C(n, \mathbb{M})$ be the CoP generated by $n$. The map

$$\varpi_r : C(n, \mathbb{M}) \longrightarrow C'(n, \mathbb{M})$$

will be the $r^{th}$ level rotation of the CoP $C(n, \mathbb{M})$ with

$$C'(n, \mathbb{M}) := \{ [k] \in C(n, \mathbb{M}) \mid [x] \in C(n, \mathbb{M}), \ x + r \equiv k \pmod{n}, \ r \in \mathbb{Z},$$

if $x + r \equiv 0 \pmod{n}$ then $k := (n + r) \pmod{n}\}.$

If the sign is positive then we say the $r^{th}$ level rotation is clockwise. Otherwise, it is an anti-clockwise $r^{th}$ level rotation for $r \neq 0$. However, if we take $r = 0$, then the rotation is trivial and the real axes joining points on the CoP remains stable. It is important to say that the result of a rotation must not be necessarily a CoP. Due to the condition $[k] \in C(n, \mathbb{M})$ it is even possible that the target set is empty. In this case we say that the $r^{th}$ level rotation fails to exist.
Theorem 3.2. The CoP $C(n)$ remains invariant under the $r$th level rotation $\varpi_r$.
That is

$$\varpi_r : C(n) \rightarrow C(n).$$

Proof. The set of weights of the images of $C(n)$ is

$$\|C'(n)\| = \{r + 1, r + 2, \ldots, r + n - 1\}_n.$$

The missing value is $(r + n - k)_n$ if $r + n - k \equiv 0(\text{mod } n)$. Therefore holds

$$k = (n + r) \text{ Mod } n.$$

And this is the substituted value by virtue of the definition. $\square$

Example 3.3. $n = 8, r = +2$

$$\|C(8)\| = \{1, 2, 3, 4, 5, 6, 7\}.$$

The critical point is [6] because $6 + 2 \equiv 0 \pmod{8}$. The set of the weights of the images of all points except of [6] is $\{3, 4, 5, 6, 7, -1\}$. Absent is 2.

As image of [6] we set $[(8 + 2) \text{ Mod } 8] = [2]$ and we get as target set

$$\|\varpi_3(C(8))\| = \{3, 4, 5, 6, 7, 2, 1\} \rightarrow \{1, 2, 3, 4, 5, 6, 7\} = \|C(8)\|.$$

$n = 8, r = -2$

The critical point is [2] because $2 - 2 \equiv 0 \pmod{8}$. The set of the weights of the images of all points except of [2] is $\{7, -1, 1, 2, 3, 4, 5\}$. Absent is 6.

As image of [2] we set $[(8 - 2) \text{ Mod } 8] = [6]$ and we get as target set

$$\|\varpi_3(C(8))\| = \{7, 6, 1, 2, 3, 4, 5\} \rightarrow \{1, 2, 3, 4, 5, 6, 7\} = \|C(8)\|.$$

Proposition 3.4. Let $C(n, M_{a,d})$ be a CoP defined as in (2.2). Then there exists not an $r$th level rotation for $r \equiv c(\text{mod } d)$ with $0 < c < d$ and $c \neq 2a(\text{mod } d)$.

Proof. W.l.o.g. we let $c \leq n$.

We observe $[n - a - kd]$ is a point of $C(n, M_{a,d})$ for $k = 0(1)\frac{n - 2a}{d}$. By applying the rotation $\varpi_r$ its weight will be transformed to

$$(n - a - kd + c) \text{ Mod } n = (c - a - kd) \text{ Mod } n$$

and because of $c \leq n$

$$= c - a - kd$$

$$\equiv (c - a) \pmod{d}$$

and because of $c \neq 2a \pmod{d}$

$$\not\equiv a \pmod{d}.$$

Hence all rotated points of $C(n, M_{a,d})$ are not points of $C(n, M_{a,d})$ and therefore the target set of the rotation is an empty set. $\square$

Proposition 3.5. Let $C(n, M_{a,d})$ be a CoP defined as in (2.3). Then $C(n, M_{a,d})$ remains invariant under the $r$th level rotation $\varpi_r$ provided $d = 2a$ and $r \equiv 0(\text{mod } d)$.

---

4We denote by $\{a, b, \ldots, z\}_n$ the set $\{a \text{ Mod } n, b \text{ Mod } n, \ldots, z \text{ Mod } n\}$.

5Because of $n \in M_{2a,d}$ is it a positive integer.
Proof. First we recall that \( n \equiv 2a \pmod{d} \). Under the assumption \( d = 2a \) it certainly follows that \( n \equiv 0 \pmod{d} \). Now, let \((x + r) \mod n = c\) be the weight of a rotated point \([x]\). Then it is easy to see that the following congruence condition is valid

\[
x + r \equiv c \pmod{n} \quad \text{and because} \quad n \equiv 0 \pmod{d}
\]

On the other hand the congruence conditions \( x \equiv a \pmod{d} \) and \( r \equiv 0 \pmod{d} \) imply

\[
x + r \equiv a \pmod{d}.
\]

Hence we have \( a = c \) and \( x + r \equiv a \pmod{d} \). Therefore all image points \( C(n, M_{a,d}) \) are members of \( M_{a,d} \) and less than \( n \). In principle all image points of the \( r^{th} \) level rotation of the CoP \( C(n, M_{a,d}) \) are again points of the CoP \( C(n, M_{a,d}) \). This proves the claim that CoPs of the form \( C(n, M_{a,d}) \) remains invariant under some \( r^{th} \) level rotation with special conditions.

\[\square\]

Example 3.6. \( n = 24, a = 2, d = 4, r = 4 \)
\[
\| C(24, M_{2,4}) \| = \{2, 6, 10, 14, 18, 22\} \quad \text{and is}
\]
\[
\| \omega_4 (C(24, M_{2,4})) \| = \{6, 10, 14, 18, 22, 2\} \to \{2, 6, 10, 14, 18, 22\}.
\]

Corollary 3.7. For conditions espoused in Proposition 3.4 and of Proposition 3.5 the \( r^{th} \) level rotation of a CoP \( C(n, M_{a,d}) \) results in a set which is a real subset of \( C(n, M_{a,d}) \).

Definition 3.8. Let \( M \subseteq \mathbb{N} \) with \( n \in \mathbb{N} \) and \( C(n, M) \) be the CoP generated by \( n \).

The map

\[
\delta_r : C(n, M) \to C(n, M)
\]

will be the \( r^{th} \) scale dilation of the CoP \( C(n, M) \) with

\[
C_r(n, M) := \{ [x] \in C(n + r, M) \mid r \in \mathbb{Z}, \ n + r > 1 \}.
\]

If the sign is positive then we say the \( r^{th} \) scale dilation is an expansion. Otherwise, it is an \( r^{th} \) scale compression for \( r \neq 0 \). However if we take \( r = 0 \), then the dilation is a trivial dilation and the CoP remains invariant under the dilation.

Remark 3.9. It is important to note that if the base set is taken to be the set of natural numbers \( \mathbb{N} \), then the image set of dilation collapses to the following

\[
\delta_r (C(n)) := C_r(n) = \{ [x] \mid x \in \mathbb{N}_{n+r-1}, \ r \in \mathbb{Z}, \ n + r > 1 \}
\]

(3.1)

Additionally, it is important to point out that in case \( r < 0 \) some points of \( C(n) \) have the same image where as in the case \( r > 0 \) some points of \( C(n) \) have more than one image.

As it happens, dilation at any scale between CoPs have the natural tendency of translating the generator of the source CoP by the size of the scale of the dilation. However it is somewhat difficult to define dilation on individual points in a given CoP. Any perceived dilation map could manifestly work on a typical CoP but it may proved handicapped for some other CoPs. In the sense that some points may
poke outside the target CoP under this fixed dilation. In light of this anomaly, we ask the following questions

**Question 3.10.** Let \( M \subseteq N \). Does there exists a well-defined dilation

\[
\delta_r : \mathcal{C}(n, M) \to \mathcal{C}(m, M)
\]

on each \([x] \in \mathcal{C}(n, M)\) for all CoPs?

Put it differently, Question 3.10 asks if there exists a fixed map that assigns each points in a typical CoP to its target CoP in a sufficiently uniform way. That is to say, the map we seek should avoid the subtleties as espoused in our earlier discussion.

**Theorem 3.11.** Let \( n, m \in \mathbb{N} \), \( M \subseteq \mathbb{N} \) and \( \mathcal{C}(n, M) \) be a CoP admitting aligned embedding. Then there exists some dilation \( \delta_r \) such that

\[
\delta_r : \mathcal{C}(n, M) \to \mathcal{C}(m, M).
\]

**Proof.** It is evident that for \( m = n \) the trivial dilation \( \delta_0 \) meets the claim. For the case \( m \neq n \) we break the proof into several cases. The case \( r \) is positive and the case it is negative. Let \( \delta_r \) be any dilation for \( r > 0 \) and suppose for any two CoP \( \mathcal{C}(n, M) \) and \( \mathcal{C}(m, M) \) with \( \mathcal{C}(m, M) \subseteq \mathcal{C}(n, M) \) there exists no dilation associating them. By virtue of the property that the CoPs admitting embedding exactly one of the following embedding holds

\[
\delta_r(\mathcal{C}(m, M)) \subseteq \mathcal{C}(n, M) \text{ or } \mathcal{C}(n, M) \subseteq \delta_r(\mathcal{C}(m, M)).
\]

We analyze each of these sub-cases. First let us assume that \( \delta_r(\mathcal{C}(m, M)) \subseteq \mathcal{C}(n, M) \). It follows that there exists some CoP \( \mathcal{C}(n, M) \) with \( \delta_r(\mathcal{C}(m, M)) \subset \mathcal{C}(s, M) \) such that \( \mathcal{C}(s, M) \subset \mathcal{C}(n, M) \). Since there exists no dilation between CoPs the following proper embedding must necessarily hold

\[
\delta_r(\mathcal{C}(m, M)) \subset \mathcal{C}(s, M) \subset \mathcal{C}(n, M).
\]

Again there exists some CoP \( \mathcal{C}(t, M) \) with \( \delta_r(\mathcal{C}(m, M)) \subset \mathcal{T}(t, M) \) such that \( \mathcal{T}(t, M) \subset \mathcal{C}(s, M) \). Then under the underlying assumption that there exists no dilation between CoPs, we obtain the following proper embedding

\[
\delta_r(\mathcal{C}(m, M)) \subset \mathcal{T}(t, M) \subset \mathcal{C}(s, M) \subset \mathcal{C}(n, M).
\]

By repeating the argument in this manner, we obtain the following infinite descending chains of covers of the smallest CoP

\[
\mathcal{C}(m + r, M) := \delta_r(\mathcal{C}(m, M)) \subset \cdots \subset \mathcal{T}(t, M) \subset \mathcal{C}(s, M) \subset \mathcal{C}(n, M).
\]

Because the CoPs admit aligned embedding we obtain the infinite descending sequence of positive integers towards the generator \( m + r \) of the last CoP

\[
n > s > t > \cdots > r + m.
\]

This is absurd, thereby ending the proof of the first sub-case. We now turn to the case \( \mathcal{C}(n, M) \subset \delta_r(\mathcal{C}(m, M)) \). Then in a similar fashion there must exist some CoP \( \mathcal{C}(t, M) \) with \( \mathcal{C}(t, M) \subset \delta_r(\mathcal{C}(m, M)) \) such that \( \mathcal{C}(n, M) \subset \mathcal{C}(t, M) \). Then under the assumption that there exists no dilation between CoP, we have the following embedding

\[
\mathcal{C}(n, M) \subset \mathcal{C}(t, M) \subset \delta_r(\mathcal{C}(m, M)).
\]
Again there exists some CoP $\mathcal{C}(s, \mathbb{M})$ with $\mathcal{C}(s, \mathbb{M}) \subseteq \delta_r(\mathcal{C}(m, \mathbb{M}))$ such that $\mathcal{C}(t, \mathbb{M}) \subset \mathcal{C}(s, \mathbb{M})$. Under the assumption that there exists no dilation between CoP, we have the following embedding

$$\mathcal{C}(n, \mathbb{M}) \subset \mathcal{C}(t, \mathbb{M}) \subset \mathcal{C}(s, \mathbb{M}) \subset \delta_r(\mathcal{C}(m, \mathbb{M})).$$

By repeating this argument indefinitely we obtain the following infinite sequence of embedding

$$\mathcal{C}(n, \mathbb{M}) \subset \mathcal{C}(t, \mathbb{M}) \subset \mathcal{C}(s, \mathbb{M}) \subset \delta_r(\mathcal{C}(m, \mathbb{M})) := \mathcal{C}(m + r, \mathbb{M}).$$

By virtue of the CoPs admitting aligned embedding, we obtain an infinite ascending sequence of positive integers towards the generator of the last CoP in the chain

$$n < t < s < \cdots < m + r.$$

This is absurdity, since we cannot have positive integers approaching a fixed positive integer for infinite amount of time. This completes the proof for the case $r > 0$. We now turn to the case $r < 0$ for any two CoP $\mathcal{C}(m, \mathbb{M}), \mathcal{C}(n, \mathbb{M})$ with $\mathcal{C}(n, \mathbb{M}) \subset \mathcal{C}(m, \mathbb{M})$. Under the main assumption exactly one of the following embedding must hold

$$\delta_r(\mathcal{C}(m, \mathbb{M})) \subset \mathcal{C}(n, \mathbb{M}) \text{ or } \mathcal{C}(n, \mathbb{M}) \subset \delta_r(\mathcal{C}(m, \mathbb{M})).$$

A similar analysis could be carried out for each of the above cases. □

**Corollary 3.12.** Because of Theorem 2.9 the CoP $\mathcal{C}(n)$ admits aligned embedding and there is the dilation $\delta_1 : \mathcal{C}(n) \rightarrow \mathcal{C}(n + 1)$ with

$$\delta_1([x]) := \begin{cases} [x] & \text{for } 1 \leq x \leq n - 1 \\ [n] & \text{additional for } x = 1 \end{cases} \quad (3.2)$$

that can produce an infinite ascending chain of CoPs

$$\mathcal{C}(n) \subset \mathcal{C}(n + 1) \subset \mathcal{C}(n + 2) \subset \cdots.$$

It is easy to see that the assignment of $[n]$ as also an image of $[1]$ is not the only possibility. Also possible would be $[n]$ as the image of $[2] \ldots [n - 1]$. In all cases we would have a correct point-to-point mapping. Hence a subset of the cross set $\mathcal{C}(n) \times \mathcal{C}(n + 1)$ for which holds:

- for each point of $\mathcal{C}(n)$ there is at least one image point of $\mathcal{C}(n + 1)$ and
- for each image point of $\mathcal{C}(n + 1)$ there is only one preimage point of $\mathcal{C}(n)$

is not a well-defined pointwise definition of the map $\mathcal{C}(n) \rightarrow \mathcal{C}(n + 1)$ because there are several such subsets.

**Corollary 3.13.** In light of Theorem 2.10 the CoP $\mathcal{C}(n, \mathbb{M}_{a,d})$ admits aligned embedding and there is the dilation $\delta_d : \mathcal{C}(n, \mathbb{M}_{a,d}) \rightarrow \mathcal{C}(n + d, \mathbb{M}_{a,d})$ with

$$\delta_d([x]) := \begin{cases} [x] & \text{for } a \leq x \leq n - a \\ [n - a + d] & \text{additional for } x = a \end{cases}$$

that can generate an infinite ascending chain of CoPs

$$\mathcal{C}(n, \mathbb{M}_{a,d}) \subset \mathcal{C}(n + d, \mathbb{M}_{a,d}) \subset \mathcal{C}(n + 2d, \mathbb{M}_{a,d}) \subset \cdots.$$
4. Special Maps of Circles of Partition

In this section we introduce and study the notion of several special maps of circles of partition. We launch more formally the following languages.

**Definition 4.1.** Let $\mathbb{M} \subseteq \mathbb{N}$ and $C(n, \mathbb{M}) \neq \emptyset$ be a CoP containing the axis $L_{[a],[b]}$. By the flipping of the CoP $C(n, \mathbb{M})$ along the so called flipping axis $L_{[a],[b]}$, we mean the map

$$\vartheta_{[a],\mathbb{M}} : C(n, \mathbb{M}) \rightarrow C(m, \mathbb{M})$$

with $\vartheta_{[a],\mathbb{M}}([a]) = [a]$ and $\vartheta_{[a],\mathbb{M}}([b]) = [b]$ such that for any two $[x], [y] \in C(n, \mathbb{M})$ with $[x], [y] \neq [a], [b]$ holds

$$\|\vartheta_{[a],\mathbb{M}}([x])\| + \|\vartheta_{[a],\mathbb{M}}([y])\| \neq n$$

A flipping axis can also be a degenerated axis $L_{[a]}$. We say the CoP $C(n, \mathbb{M})$ is susceptible to flipping if there exists such a map.

**Example 4.2.** Let be $\mathbb{M} = \mathbb{P}$ and $n = 20$. The CoP $C(20, \mathbb{P})$ is the set $\{[3], [7], [13], [17]\}$ with two axes $L_{[3],[17]}$ and $L_{[7],[13]}$. Then the map

$$\vartheta_{[3],[17]} : C(20, \mathbb{P}) \rightarrow C(22, \mathbb{P})$$

with $C(22, \mathbb{P}) = \{[3], [5], [11], [17], [19]\}$ is a flipping of $C(20, \mathbb{P})$ along the axis $L_{[3],[17]}$ if f.i.

$$\vartheta_{[3],[17]}([3]) = [3]$$
$$\vartheta_{[3],[17]}([7]) = [5]$$
$$\vartheta_{[3],[17]}([13]) = [11]$$
$$\vartheta_{[3],[17]}([17]) = [19].$$

Hence we get $||[5]|| + ||[11]|| = 16 \neq 20$ or $||[5]|| + ||[19]|| = 24 \neq 20$.

Vice versa there are no axis points of $C(22, \mathbb{P})$ that are also points of $C(20, \mathbb{P})$. Hence there exists no flipping from $C(22, \mathbb{P})$ to $C(20, \mathbb{P})$ along an axis of $C(22, \mathbb{P})$.

**Proposition 4.3.** Let $\mathbb{M}_{a,d}$ be defined as in (22) with $0 < a \leq d$. Then the CoP $C(n, \mathbb{M}_{a,d})$ is susceptible to flipping if and only if $n > m$.

**Proof.** We must regard that in order to get $C(n, \mathbb{M}_{a,d}) \neq \emptyset$ it must be $n \in \mathbb{M}_{2a,d}$. Then is $n - a \in \mathbb{M}_{a,d}$. The same is valid for $C(m, \mathbb{M}_{a,d})$.

We assume that $n > m$. Then holds with Corollary 24.11

$$C(n, \mathbb{M}_{a,d}) \supset C(m, \mathbb{M}_{a,d}).$$

Due to $n \in \mathbb{M}_{2a,d}$ holds $\frac{n - 2a}{d} \in \mathbb{N}$. The weights of $C(n, \mathbb{M}_{a,d})$ are

$$\|C(n, \mathbb{M}_{a,d})\| = \left\{ a + k \cdot d \mid k = 0, 1, 2, \ldots, \frac{n - 2a}{d} \right\}.$$  

Hence $C(n, \mathbb{M}_{a,d})$ has

$$l_n = \frac{n - 2a}{d} + 1 \text{ members.}$$

This is in accordance with the general counting function for CoPs:
\[ ||C(n, M_{a,d})|| = 1 + \sum_{1 \leq x \leq n-a \atop x \equiv a \pmod{d}} 1 \]
\[ = 1 + \frac{n - 2a}{d}. \]

The addition of 1 is required because the counting starts with 0. Now we must distinguish two cases:

rC: The CoP \( C(n, M_{a,d}) \) has a real center.

dC: The CoP \( C(n, M_{a,d}) \) has a deleted center.

In the case rC holds \( l_n \) is odd and \( l_n \) is even in the other case. Now we choose in the case rC the degenerated axis \( L_{[u]} \) of the CoP \( C(n, M_{a,d}) \) as the flipping axis, in the case dC those which is the closest one to the center of the CoP. The weights of \( [u], [v] \) are \( u = \frac{n}{2} \) for the case rC and \( u = \frac{n + d}{2}, \ v = \frac{n + d}{2} \) in the other case. In order to satisfy the conditions of Definition 4.1

\[ \vartheta_{[u],[v]}([u]) = [u] \text{ and } \vartheta_{[u],[v]}([v]) = [v] \]

the last point of \( C(m, M_{a,d}) \) should be \([v]\). Due to Corollary 2.6 we get for \( m \) as the sum of the weights of the first and the last member of CoP \( C(m, M_{a,d}) \)

\[ m = \begin{cases} a + \frac{n}{2} & \text{for rC} \\ a + \frac{n + d}{2} & \text{for dC.} \end{cases} \tag{4.1} \]

Analogously to \( C(n, M_{a,d}) \) holds for the number of members of \( C(m, M_{a,d}) \)

\[ l_m - 1 := \sum_{1 \leq x \leq m-a \atop x \equiv a \pmod{d}} 1 = \frac{m - 2a}{d} \]
\[ = \begin{cases} a + \frac{n}{2} - 2a = \frac{n - 2a}{2} = \frac{l_n - 1}{2} & \text{for rC} \\ a + \frac{n + d}{2} - 2a = \frac{n - 2a}{2} + 1 = \frac{l_n}{2} & \text{for dC.} \end{cases} \]

Hence we obtain for both cases

\[ l_m = \left\lfloor \frac{l_n}{2} \right\rfloor + 1. \]

All these fulfills the following map

\[ \vartheta_{[u],[v]}(x) = a + k(x) \cdot d \text{ with} \]
\[ \frac{x - a}{d} \equiv k(x) \pmod{l_m}. \]

This map assigns each point of \( C(n, M_{a,d}) \) to a point of \( C(m, M_{a,d}) \).

The heaviest point of CoP \( C(m, M_{a,d}) \) is \([m - a]\). In the case rC the flipping axis is \( L_{[u]} \) with \( u = \frac{n}{2} \) and we get with (4.1)

\[ \left\| \vartheta_{[v],[v]} \left( \left[ \frac{n}{2} \right] \right) \right\| = m - a = \frac{n}{2}. \]
Hence the requirement \(|\vartheta_{[u],[v]}([v])| = u = v = \frac{n}{2}\) is fulfilled. In the case \(dC\) we get with (4.1)

\[
\left\|\vartheta_{[u],[v]}\left(\left\lceil \frac{n+d}{2}\right\rceil\right)\right\| = m - a = \frac{n + d}{2} = v.
\]

Therefore holds \(u = v - d = \frac{n-d}{2}\). And for each two points \([x],[y] \in C(n,M_{a,d})\) with \([x],[y] \notin [u],[v]\) holds

\[
\left\|\vartheta_{[u],[v]}([x])\right\| + \left\|\vartheta_{[u],[v]}([y])\right\| = n
\]

because \(\vartheta_{[u],[v]}([u]) = [u]\) and \(\vartheta_{[u],[v]}([v]) = [v]\) are the two heaviest points of \(C(m,M_{a,d})\) in case \(dC\) respectively is the heaviest point of \(C(n,M_{a,d})\) in \(rC\) with the sum of weights of the two heaviest points \(\leq n\). The weight sum of all others is lesser. Thereby the first part of the claim is proven.

If on the other hand holds \(n \leq m\) then the source CoP is a subset of the target CoP. All axes points of \(C(n,M_{a,d})\) are identically mapped into \(C(m,M_{a,d})\). And for all these \(\vartheta_{[u],[v]}([x])\) and \(\vartheta_{[u],[v]}([y])\) from any axis \(L_{[x],[y]}\) of \(C(n,M_{a,d})\) holds

\[
\left\|\vartheta_{[u],[v]}([x])\right\| + \left\|\vartheta_{[u],[v]}([y])\right\| = n.
\]

This is a contradiction to the requirements of the claim. \(\square\)

Remark 4.4. Note that due to \(M_{1,1} = \mathbb{N}\) this statement also holds for each CoP \(C(n)\).

Proposition 4.5. The chosen axis closest to the center of the CoP \(C(n,M_{a,d})\) resp. the degenerated axis in case of existing center is the only one for flipping along an axis in the case of \(M = M_{a,d}\).

Proof. For all axes \(L_{[x],[y]} \in C(n,M_{a,d})\) holds\(^6\)

\[
x \leq \frac{n}{2} \leq y.
\]

Therefore there is no axis \(L_{[x],[y]}\) with \(y < \frac{n}{2}\). For the chosen axis \(L_{[u],[v]}\) closest to the center of \(C(n,M_{a,d})\) holds

\[
\frac{n - d}{2} \leq \frac{\|[u]\|}{\|v\|} \leq \frac{n + d}{2}.
\]

The only opposite of this are axes \(L_{[u],[w]}\) with \(\frac{\|[w]\|}{\|v\|} < \frac{n-d}{2}\) and its axis partner with \(\frac{\|z\|}{\|y\|} > \frac{n+d}{2}\). Then between \(\|[w]\|\) and \(\|z\|\) there is at least one axis \(L_{[x],[y]}\) with \(w < x \leq y < z\) and \(x + y = n\). This is a contradiction to the requirements of flipping along the axes \(L_{[w],[z]}\). Hence only the axis \(L_{[u],[v]}\) resp. \(L_{[u]}\) with

\[
rC: \frac{\|[u]\|}{\|v\|} = \frac{n}{2}, \|v\| = \frac{n + d}{2}
\]

satisfies the requirements of a flipping axis. \(\square\)

It is quite suggestive from this proposition the notion of flipping of CoPs under \(M = M_{a,d}\) can be thought of as the process of slicing a circle into two equal half and overturning one half to lie perfectly on top of the other half, thereby forming a geometric structure akin to the semi-circle.

\(^6\)W.l.o.g. we assume \(x \leq y\) for all axes \(L_{[x],[y]}\). In case of existing center is \(L_{[x]} = L_{[x],[x]}\).
Example 4.6. We choose $a = 2, d = 4$ and hence $M = M_{2,4}$. Then with $n = 28$ is
\[
\|C(28, M_{2,4})\| = \{2, 6, 10, 14, 18, 22, 26\},
\]
\[
l_n = \frac{28 - 2 \cdot 2}{4} + 1 = 7,
\]
\[
l_m = \left\lfloor \frac{7}{2} \right\rfloor + 1 = 4 \quad \text{and}
\]
\[
m = 2 + \frac{28}{2} = 16
\]
with the flipping axis $L_{14}$. Hence is
\[
\|\partial_{[14],[14]}(C(28, M_{2,4}))\| = \|C(16, M_{2,4})\|
\]
\[
\{2, 6, 10, 14\}.
\]
All weight sums of any two members of $\{[2], [6], [10], [14]\} \setminus \{14\}$ are less than $28$. If we would take $L_{[6],[22]}$ as flipping axis we would obtain as target set
\[
C(24, M_{2,4}) = \{[2], [6], [10], [14], [18], [22]\}.
\]
And here would be possible out of $\{[6], [22]\}$ one weight sum contradicting to the requirements:
\[
10 + 18 = 28.
\]

Now we introduce and study the concept of filtration of the CoPs. At first we deal with the filtration along an axis.

Definition 4.7. Let $M \subseteq \mathbb{N}$ with the corresponding CoP $C(n, M)$ containing the axis $L_{[x],[y]}$. By the filtration of the CoP $C(n, M)$ along the filtration axis $L_{[x],[y]}$ we mean the map
\[
\Phi_{[x],[y]} : C(n, M) \to C(m, M)
\]
such that $[x],[y] \notin C(m, M)$ for some $m \in \mathbb{N} \setminus \{1\}$ and there exists the so called co-axis $L_{[u],[v]}$ of $C(n, M)$ so that $L_{[u],[a]}$ and $L_{[v],[b]}$ are axes of $C(m, M)$ for some $[a],[b] \in M$. We say the CoP $C(n, M)$ is susceptible to filtration if there exists such a map. The filtration axis can also be a degenerated axis.

Also here an example will demonstrate this special map.

Example 4.8. Let be again $M = \mathbb{P}$ and $n = 20$. Then the map
\[
\Phi_{[7],[13]} : C(20, \mathbb{P}) \to C(22, \mathbb{P})
\]
is a filtration of $C(20, \mathbb{P})$ along the filtration axis $L_{[7],[13]}$ due to the target CoP
\[
C(22, \mathbb{P}) = \{3, 5, 11, 17, 19\}
\]
contains the axes $L_{[3],[19]}$ and $L_{[7],[5]}$ where $L_{[3],[17]}$ is the co-axis of $C(20, \mathbb{P})$.

Example 4.9. Again we take $M = \mathbb{P}$ but $n = 46$. It is
\[
\|C(46, \mathbb{P})\| = \{3, 5, 17, 23, 29, 41, 43\} \quad \text{and}
\]
\[
\|C(50, \mathbb{P})\| = \{3, 7, 13, 19, 31, 37, 43, 47\}.
\]
Then the map
\[
\Phi_{[23]} : C(46, \mathbb{P}) \to C(50, \mathbb{P})
\]
is a filtration of $C(46, \mathbb{P})$ along the degenerated axis $L_{[23]}$ due to the target CoP contains $L_{[3],[47]}$ and $L_{[7],[43]}$ where $L_{[3],[43]}$ is the co-axis of $C(46, \mathbb{P})$. 
Proposition 4.10. The CoP $\mathcal{C}(n, \mathbb{M})$ admits aligned embedding is not susceptible to filtration along an axis.

Proof. The claim is true if one of the following statements holds

(A) The CoP $\mathcal{C}(n, \mathbb{M})$ has no filtration axis.
(B) The CoP $\mathcal{C}(n, \mathbb{M})$ has no co-axis

We suppose at first $n \leq m$. Then holds with Theorem 2.10

$$\mathcal{C}(n, \mathbb{M}) \subseteq \mathcal{C}(m, \mathbb{M}).$$

Then the images of all axis points of the source CoP are points of the target CoP. Hence there is no filtration axis (A).

Now we look for $m < n$. In this case holds with Corollary 2.11

$$\mathcal{C}(n, \mathbb{M}) \supset \mathcal{C}(m, \mathbb{M}).$$

At first let be $m < \frac{n}{2}$. In this case the images of the end points of all axes of $\mathcal{C}(n, \mathbb{M})$ do not exist in $\mathcal{C}(m, \mathbb{M})$. Hence there is no co-axis (B).

At last we look for $\frac{n}{2} \leq m < n$. In this case the images of the begin points of all axes of $\mathcal{C}(n, \mathbb{M})$ are points of $\mathcal{C}(m, \mathbb{M})$. Hence there is no filtration axis (A). \hfill \Box

Definition 4.11. Let $\mathbb{M} \subseteq \mathbb{N}$ with the corresponding CoP $\mathcal{C}(n, \mathbb{M})$ containing the axis $L_{[x],[y]}$. By the reduction of the CoP $\mathcal{C}(n, \mathbb{M})$ in the base set $\mathbb{M}$ we mean the map

$$\phi_{[x],[y]} : \mathcal{C}(n, \mathbb{M}) \rightarrow \mathcal{C}(n, \mathbb{M}^*)$$

with $\mathbb{M}^* := \mathbb{M} \setminus \{x, y\}$. We say the CoP $\mathcal{C}(n, \mathbb{M})$ is susceptible to reduction if there exists such a map.

Proposition 4.12. Let $\mathbb{M}_{a,d}$ be defined as in (2.4). Then the CoP $\mathcal{C}(n, \mathbb{M}_{a,d})$ is susceptible to reduction.

Proof. W.l.o.g. we suppose $x < y$ and take

$$\phi_{[x],[y]}([u]) = \begin{cases} [u] & \text{if } u \neq x \text{ and } u \neq y \\ [u+d] & \text{if } u = x \\ [u-d] & \text{if } u = y \end{cases}$$

for all points $[u] \in \mathcal{C}(n, \mathbb{M}_{a,d})$. Due to all members of $\mathbb{M}_{a,d}$ have the same distance $d$ it holds that if $u \in \mathbb{M}_{a,d}$ then is also $u \pm d \in \mathbb{M}_{a,d}$ and

$$\|\phi_{[x],[y]}([x])\| + \|\phi_{[x],[y]}([y])\| = x + d + y - d = n$$

because $L_{[x],[y]}$ is an axis of $\mathcal{C}(n, \mathbb{M}_{a,d})$. \hfill \Box

Due to $\mathbb{M}_{1,1} = \mathbb{N}$ this proposition holds for $\mathcal{C}(n)$ too.

5. Stable and Unstable Points on the Circle of Partition

In this section we launch the notion of stability of a sequence under a given dilation.

Definition 5.1. Let $\Theta(n)$ be a subsequence of $\mathbb{N}_n$ and suppose the CoP $\mathcal{C}(n, \mathbb{M}) \neq \emptyset$. Let $L_{[x],[y]}$ be a real axis of the CoP $\mathcal{C}(n, \mathbb{M})$ with $x, y \in \Theta(n)$. Then we say the point $[x] \in \mathcal{C}(n, \mathbb{M})$ is stable relative to the subsequence $\Theta(n)$ under the $r^{th}$ level rotation $\varpi_r : \mathcal{C}(n, \mathbb{M}) \rightarrow \mathcal{C}(n, \mathbb{M})$ if $\|\varpi_r([x])\| \in \Theta(n)$ and $\exists z \in \Theta(n)$ such that $L_{[\varpi_r([x]),[z]]}$ is also a real axis of the CoP $\mathcal{C}(n, \mathbb{M})$. We say the subsequence $\Theta(n)$ is
stable under the \( r^{th} \) level rotation \( \varpi_r \) if all points in \( [x] \in \mathcal{C}(n, \mathbb{M}) \) with \( x \in \Theta(n) \) are stable.

**Definition 5.2.** Let \( \Theta(n) \) be a subsequence of \( \mathbb{N}_n \) and suppose the CoP \( \mathcal{C}(n, \mathbb{M}) \neq \emptyset \). Let \( \mathbb{L}_{[x],[y]} \) be a real axis of the CoP \( \mathcal{C}(n, \mathbb{M}) \) with \( x, y \in \Theta(n) \). Then we say the point \( [x] \in \mathcal{C}(n, \mathbb{M}) \) is stable relative to the subsequence \( \Theta(n) \) under the \( r^{th} \) scale dilation \( \delta_r : \mathcal{C}(n, \mathbb{M}) \to \mathcal{C}(s, \mathbb{M}) \) if \( ||\delta_r([x])|| \in \Theta(n) \) and \( \exists r \in \Theta(n) \) such that \( \mathbb{L}_{[\delta_r([x]),[z]]} \) is also a real axis of the CoP \( \mathcal{C}(s, \mathbb{M}) \). We say the subsequence \( \Theta(n) \) is stable under the \( r^{th} \) scale dilation \( \delta_r \) if all points in \( [x] \in \mathcal{C}(n, \mathbb{M}) \) with \( x \in \Theta(n) \) are stable.

Next we establish an important result in the special case where the base set is the set \( \mathbb{N} \) of natural numbers.

**Proposition 5.3.** Let \( \Theta(n) = \mathbb{N}_{n-1} \) and let \( \delta_r : \mathcal{C}(n) \to \mathcal{C}(m) \) be a dilation. Then the subsequence \( \Theta(n) \) is stable if and only if \( n \geq m \).

**Proof.** In the case \( m = n \) then the dilation is trivial and the claim is trivially true. Suppose the sequence \( \Theta(n) \) is stable under the dilation

\[
\delta_r : \mathcal{C}(n) \to \mathcal{C}(m)
\]

and assume to the contrary that \( n < m \). Then the dilation is an expansion. It follows that for all \([x] \in \mathcal{C}(n)\) with \( x \in \Theta(n) \) there exists \( z \in \Theta(n) \) such that \( z + ||\delta_r([x])|| = m \). Under the assumption \( n < m \) and by virtue of Theorem 2.9 we have the embedding \( \mathcal{C}(n) \subset \mathcal{C}(m) \) and for all \( x \in \Theta(n) \) holds \([x] \in \mathcal{C}(n)\) and \( 1 + x \leq n < m \). There exist some \([y] \in \mathcal{C}(n)\) such that \( \delta_r([y]) = [1] \) but there exists no \( z \in \Theta(n) \) such that \( 1 + z = m \). It follows that the point \([y]\) is not a stable point under \( \delta_r \). This contradicts the claim that \( \Theta(n) \) is stable and so \( n < m \) is impossible. Conversely let us suppose that \( m < n \) and consider the dilation

\[
\delta_r : \mathcal{C}(n) \to \mathcal{C}(m).
\]

We note that for any point \([x] \in \mathcal{C}(n)\) there exist some \( k < m < n \) such that \( ||\delta_r([x])|| + k = m \). Because \( k \in \mathbb{N}_{n-1} = \Theta(n) \) it follows that the subsequence \( \Theta(n) \) is stable under any dilation \( \delta_r \).

Next we show that any consecutive subsequence of \( \mathbb{N}_n \) containing none of its degenerate terms must be stable under the simple dilation. We formalize this assertion in the following results.

**Proposition 5.4.** Let \( \Theta(n) := \{x, x+1, \ldots, n-x, n-x+1\} \) be a subsequence of \( \mathbb{N}_n \) for any \( 1 < x < \frac{n}{2} \) and \( \delta_r : \mathcal{C}(n) \to \mathcal{C}(n+1) \) be an expansion. Then \( \Theta(n) \) is stable under the expansion \( \delta_r \).

**Proof.** For any point \([x] \in \mathcal{C}(n)\) we see that \( \mathbb{L}_{[x],[n-x]} \) is a real axis of the CoP. By enforcing \( 1 < x < \frac{n}{2} \), then we observe that the dilation \( \delta_1 : \mathcal{C}(n) \to \mathcal{C}(n+1) \) with

\[
\delta_1([x]) := \begin{cases} [x] & \text{for } 1 \leq x \leq n-1 \\ [n] & \text{additional for } x = 1 \end{cases}
\]

is achievable. It follows that for each \( 1 < x < \frac{n}{2} \) the line \( \mathbb{L}_{[x],[n-x+1]} \) is also a real axis of the CoP \( \mathcal{C}(n+1) \). This proves that \( \Theta(n) \) is stable under the dilation \( \delta_r \). □
6. The Density of Points on the Circle of Partition

In this section we introduce the notion of density of points on CoP \( C(n, M) \) for \( M \subseteq \mathbb{N} \). We launch the following language in that regard. We consider in this section only real axes. Therefore we don’t use the attribute \textit{real} in this section.

\textbf{Definition 6.1.} Let be \( H \subset \mathbb{N} \). Then the quantity
\[
D(H) = \lim_{n \to \infty} \frac{|H \cap N_n|}{n}
\]
denotes the density of \( H \).

\textbf{Definition 6.2.} Let \( C(n, M) \) be CoP with \( M \subset \mathbb{N} \) and \( n \in \mathbb{N} \). Suppose \( H \subset M \) then by the density of points \( x \in C(n, M) \) such that \( x \in H \), denoted \( D(H C(\infty, M)) \), we mean the quantity
\[
D(H C(\infty, M)) = \lim_{n \to \infty} \frac{\# \{ L[x] : y \in C(n, M) \mid \{ x, y \} \cap H \neq \emptyset \}}{\nu(n, M)}.
\]

\textbf{Remark 6.3.} The notion of the density of points as espoused in Definition 6.2 provides a passage between the density of the corresponding weight set of points. This possibility renders this type of density as a black box in studying problems concerning partition of numbers into specialized sequences taking into consideration their density.

\textbf{Proposition 6.4.} Let \( C(n) \) with \( n \in \mathbb{N} \) be a CoP and \( H \subset \mathbb{N} \). Then the following inequality holds
\[
D(H) = \lim_{n \to \infty} \frac{|H \cap N_n|}{n} \leq D(H C(\infty)) \leq \lim_{n \to \infty} \frac{|H \cap N_n|}{n - \frac{1}{2}} = 2D(H).
\]

\textbf{Proof.} The upper bound is obtained from a configuration where no two points \( [x], [y] \in C(n) \) such that \( x, y \in H \) lie on the same axis of the CoP. That is, by the uniqueness of the axes of CoPs with \( \nu(n, H) = 0 \), we can write
\[
\# \{ L[x], [y] \in C(n) \mid \{ x, y \} \cap H \neq \emptyset \} = \nu(n, H) + \# \{ L[x], [y] \in C(n) \mid x \in H, y \in N \setminus H \}
= \# \{ L[x], [y] \in C(n) \mid x \in H, y \in N \setminus H \}
= |H \cap N_n|.
\]
The lower bound however follows from a configuration where any two points \( [x], [y] \in C(n) \) with \( x, y \in H \) are joined by a axis of the CoP. That is, by the uniqueness of the axis of CoPs with \( \# \{ L[x], [y] \in C(n) \mid x \in H, y \in N \setminus H \} = 0 \), then we can write
\[
\# \{ L[x], [y] \in C(n) \mid \{ x, y \} \cap H \neq \emptyset \} = \nu(n, H)
= \left\lfloor \frac{|H \cap N_n|}{2} \right\rfloor.
\]
\( \square \)

\textbf{Proposition 6.5.} Let \( H \subset \mathbb{N} \) and suppose \( D(H C(\infty)) \) exists. Then the following properties hold:
(i) \( D(\mathbb{N}_{C(\infty)}) = 1 \) and \( D(\mathbb{H}_{C(\infty)}) \leq 1 \) and additionally that \( D(\mathbb{H}_{C(\infty)}) < 1 \) provided \( D(\mathbb{N} \setminus \mathbb{H}) > 0. \)

(ii) \( 1 - \lim_{n \to \infty} \frac{\nu(n, \mathbb{N} \setminus \mathbb{H})}{\nu(n, \mathbb{N})} = D(\mathbb{H}_{C(\infty)}). \)

(iii) If \( |\mathbb{H}| < \infty \) then \( D(\mathbb{H}_{C(\infty)}) = 0. \)

Proof. It is easy to see that the first part of Property (i) and (iii) are both easy consequences of the definition of density of points on the CoP \( C(n) \) and Proposition 6.4. We establish the second part of property (i) and Property (ii), which is the less obvious case. We observe by the uniqueness of the axes of CoPs that we can write

\[
1 = \lim_{n \to \infty} \frac{\nu(n, \mathbb{N})}{\nu(n, \mathbb{N})}
= \lim_{n \to \infty} \frac{\# \{ (x, y) \in C(n) \mid x \in \mathbb{H}, y \in \mathbb{N} \setminus \mathbb{H} \}}{\nu(n, \mathbb{N})}
+ \lim_{n \to \infty} \frac{\nu(n, \mathbb{H})}{\nu(n, \mathbb{N})} + \lim_{n \to \infty} \frac{\nu(n, \mathbb{N} \setminus \mathbb{H})}{\nu(n, \mathbb{N})}
= D(\mathbb{H}_{C(\infty)}) + \lim_{n \to \infty} \frac{\nu(n, \mathbb{N} \setminus \mathbb{H})}{\nu(n, \mathbb{N})}
\]

and (ii) follows immediately. The second part of (i) follows from the above expression and exploiting the inequality

\[
\lim_{n \to \infty} \frac{\nu(n, \mathbb{N} \setminus \mathbb{H})}{\nu(n, \mathbb{N})} \leq \lim_{n \to \infty} \frac{\left\lfloor \frac{|\mathbb{N} \setminus \mathbb{H}|}{2} \right\rfloor}{\frac{n}{2}} = D(\mathbb{N} \setminus \mathbb{H})
\]

□

It is important to notice that the same result may not hold if we replace the set of natural numbers \( \mathbb{N} \) with a special subset \( M \). Next we transfer the notion of the density of a sequence to the density of corresponding points on the CoP \( C(n) \). This notion will play a crucial role in our latter developments.

**Proposition 6.6.** Let \( \mathbb{H} \subset (0,1] \) and \( \mathbb{H} \) be a sequence with \( \mathbb{H} \subset \mathbb{N} \) and \( C(n) \) be a CoP. If \( D(\mathbb{H}) \geq \epsilon \) then \( D(\mathbb{H}_{C(\infty)}) \geq \epsilon. \)

Proof. The result follows by exploiting the inequality in Proposition 6.4 □

**Proposition 6.7.** Let \( \mathbb{H} \) be a sequence with \( \mathbb{H} \subset \mathbb{N} \). For \( \epsilon \in (0,1] \) and any \( k \in \mathbb{N} \) if

\[
|\mathbb{H} \cap \mathbb{N}| \geq n \epsilon
\]

and the common difference of arithmetic progressions in \( \left( \mathbb{N} \setminus \mathbb{H} \right) \cap \mathbb{N} \) are different from those in \( \mathbb{H} \cap \mathbb{N} \), then there exists some rotation \( \omega_r \) such that the CoP \( C(n) \) contains at least \( (k - 1) \) stable points \( [x] \) for \( x \in \mathbb{H} \cap \mathbb{N} \).

Proof. Suppose \( \mathbb{H} \subset \mathbb{N} \) with the underlying conditions, then by Theorem 1.1 the sequence \( \mathbb{H} \) contains fairly long arithmetic progressions of length \( k \). We enumerate them as follows

\[
x, x + s, x + 2s, \ldots, x + (k - 1)s
\]
for \( s \in \mathbb{N} \). It follows that the corresponding points on the CoP \( C(n) \), namely

\[ [x], [x + s], [x + 2s], \ldots, [x + (k - 1)s] \in C(n) \]

are equally spaced and the chord joining two of these adjacent points are of equal distance. Similarly points on the other end of the axis are equally spaced and the chords joining any of these two adjacent points are of equal distance \( s \). Let us enumerate them as follows

\[ [n - x], [n - x - s], [n - x - 2s], \ldots, [n - x - (k - 1)s] \in C(n). \]

Apply the rotation \( \varpi_r \) by choosing \( r = s \) then we have

\[ \varpi_s([x]), \varpi_s([x + s]), \ldots, \varpi_s([x + (k - 1)s]). \]

The image of these points under the rotation is given by

\[ [x + s], [x + 2s], \ldots, [x + (k - 1)s], [x + ks]. \]

Since the point \( [x + ks] \) a priori was not on any of the axes considered at least \( (k - 1) \) points on these axes will be transferred to their immediate next point on an axis containing all points \( [x] \) with \( x \in \mathbb{H} \cap \mathbb{N}_n \). Similarly under the rotation the corresponding images of the points on the other half of the CoP lying on the same axis with these points have the images

\[ \varpi_s([n - x]), \varpi_s([n - x - s]), \ldots, \varpi_s([n - x - (k - 1)s]) \]

which we can recast as

\[ [n - x - s], [n - x - 2s], \ldots, [n - x - (k - 1)s], [n - x - ks]. \]

At least \( (k - 1) \) of these points are points on the previous axis and they lying on the same axis with the points on the other half of the CoP. Since the sequence

\[ n - x - s, n - x - 2s, \ldots, n - x - ks \]

are in arithmetic progression, it follows by the assumption

\[ n - x - s, n - x - 2s, \ldots, n - x - ks \in \mathbb{H} \cap \mathbb{N}_n. \]

This completes the proof. \( \square \)

**Proposition 6.8.** Let \( \mathbb{H} \subset \mathbb{N} \) such that \( \mathbb{H} = \mathbb{J} \cup \mathbb{T} \) with \( \mathbb{J} \cap \mathbb{T} = \emptyset \) and \( D(\mathbb{T}) = 0 \). Then the following inequalities hold for density of CoPs

\[ D(\mathbb{H}_{C(\infty)}) = D(\mathbb{J}_{C(\infty)}) \]

and

\[ D((\mathbb{N} \setminus \mathbb{H})_{C(\infty)}) \leq D((\mathbb{N} \setminus \mathbb{J})_{C(\infty)}). \]
Proof. Appealing to Proposition 6.5, it follows by the uniqueness of the axes of CoPs the following decomposition

\[
\mathcal{D}(\mathbb{H}_{\mathcal{C}(\infty)}) = \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid \{ x, y \} \cap (J \cup T) \neq \emptyset \}}{\left\lfloor \frac{n}{2} \right\rfloor}
\]

\[
= \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n, J) \}}{\left\lfloor \frac{n}{2} \right\rfloor}
+ \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n, T) \}}{\left\lfloor \frac{n}{2} \right\rfloor}
+ \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid x \in J, y \in T \}}{\left\lfloor \frac{n}{2} \right\rfloor}
+ \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid x \in J, y \in N \setminus J \}}{\left\lfloor \frac{n}{2} \right\rfloor}
+ \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid x \in T, y \in N \setminus T \}}{\left\lfloor \frac{n}{2} \right\rfloor}
\]

Under the inequalities

\[
\lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n, T) \}}{\left\lfloor \frac{n}{2} \right\rfloor} \leq \lim_{n \to \infty} \frac{|T \cap N_n|}{\left\lfloor \frac{n}{2} \right\rfloor} = 0
\]

and

\[
\lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid x \in J, y \in T \}}{\left\lfloor \frac{n}{2} \right\rfloor} \leq \lim_{n \to \infty} \frac{|T \cap N_n|}{\left\lfloor \frac{n}{2} \right\rfloor} = 0
\]

and

\[
\lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid x \in T, y \in N \setminus T \}}{\left\lfloor \frac{n}{2} \right\rfloor} \leq \lim_{n \to \infty} \frac{|T \cap N_n|}{\left\lfloor \frac{n}{2} \right\rfloor} = 0
\]

we have

\[
\mathcal{D}(\mathbb{H}_{\mathcal{C}(\infty)}) = \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid \{ x, y \} \cap (J \cup T) \neq \emptyset \}}{\left\lfloor \frac{n}{2} \right\rfloor}
\]

\[
= \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n, J) \}}{\left\lfloor \frac{n}{2} \right\rfloor}
+ \lim_{n \to \infty} \frac{\# \{ L[x], y \in \mathcal{C}(n) \mid x \in J, y \in N \setminus J \}}{\left\lfloor \frac{n}{2} \right\rfloor}
= \mathcal{D}(\mathcal{J}_{\mathcal{C}(\infty)}).
\]
Again we have the following decomposition by virtue of $\mathcal{J} \cap \mathcal{T} = \emptyset$

\[
\mathcal{D}(\{(N \setminus \mathcal{H})C(\infty)\}) = \lim_{n \to \infty} \left\lceil \frac{\# \{L[x],[y] \in C(n) \mid \{x, y\} \cap (N \setminus \mathcal{J} \cup \mathcal{T}) \neq \emptyset \}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
= \lim_{n \to \infty} \left\lceil \frac{\# \{L[x],[y] \in C(n) \mid x \in N \setminus \mathcal{J} \cap N \setminus \mathcal{T}, y \in \mathcal{J} \cup \mathcal{T} \}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
+ \lim_{n \to \infty} \left\lceil \frac{n^{\frac{1}{2}}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
\leq \lim_{n \to \infty} \left\lceil \frac{\# \{L[x],[y] \in C(n) \mid x \in N \setminus \mathcal{J} \}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
+ \lim_{n \to \infty} \left\lceil \frac{n^{\frac{1}{2}}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
+ \lim_{n \to \infty} \left\lceil \frac{\# \{L[x],[y] \in C(n) \mid x \in N \setminus \mathcal{J}, y \in \mathcal{T} \}}{n^{\frac{1}{2}}} \right\rceil
\]

since $N \setminus \mathcal{J} \cap N \setminus \mathcal{T} \subset N \setminus \mathcal{J}$. By exploiting the inequality

\[
\lim_{n \to \infty} \left\lceil \frac{n^{\frac{1}{2}}}{n^{\frac{1}{2}}} \right\rceil = 0
\]

it follows that

\[
\mathcal{D}(\{(N \setminus \mathcal{H})C(\infty)\}) \leq \lim_{n \to \infty} \left\lceil \frac{\# \{L[x],[y] \in C(n) \mid x \in N \setminus \mathcal{J}, y \in \mathcal{T} \}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
+ \lim_{n \to \infty} \left\lceil \frac{n^{\frac{1}{2}}}{n^{\frac{1}{2}}} \right\rceil
\]

\[
= \mathcal{D}(\{(N \setminus \mathcal{J})C(\infty)\}).
\]

It follows by the above analysis the inequalities

\[
\mathcal{D}(\mathcal{H}C(\infty)) = \mathcal{D}(\mathcal{J}C(\infty))
\]

and

\[
\mathcal{D}(\{(N \setminus \mathcal{H})C(\infty)\}) \leq \mathcal{D}(\{(N \setminus \mathcal{J})C(\infty)\}).
\]

In the accompanying proof we will make use of degenerate and non-degenerate points of a given set of points on a CoP. However intricate the proof might seem to be, it can be pinned down to just a simple principle. The highly dense nature of the sequence allows us to break their components into several boxes. The closest components in each of these boxes are equidistant from each other. The residue which are not dense will be thrown away into another box whose components are very sparse. We then translate a component by their gap if it ever happens to be in some dense box at the same time live on the same axis with other component. This forces the second component to also belong to some dense box. If the component on the same axis with another component does not belong to the dense box, then the components and the associated components must live in the sparse box. We can then move them into the dense box and repeat the arguments. We make
these terminologies more precise in the following definitions and then present our argument.

**Definition 6.9.** Let \( P \subseteq C(n, M) \) with \( M \subseteq \mathbb{N} \). Then a point \([x] \in P\) is a degenerate point if the line joining the point \([x]\) to the centre (resp. deleted centre) of the CoP \( C(n, M)\) is a boundary of the largest sector induced by the points in \( P\). Otherwise, we say it is a non-degenerate point in \( P\).

**Theorem 6.10.** Let \( H \subset \mathbb{N}\) and suppose that \( C(n, H) \neq \emptyset\). If for any \( \epsilon \in (0, 1]\) holds
\[
|H \cap N_n| \geq n\epsilon
\]
with
\[
D(N \setminus H) = \lim_{n \to \infty} \frac{|(N \setminus H) \cap N_n|}{n} < D(H)
\]
then there exists a dilation \( \delta_r : C(n, H) \to C(n + r, H)\) such that
\[
C(n + r, H) \neq \emptyset.
\]

**Proof.** Under the assumption \( |H \cap N_n| \geq n\epsilon\) for any \( \epsilon \in (0, 1]\), then \( H\) contains fairly long arithmetic progressions. Let us enumerate them as follows
\[
G_1 = \{x_1 + kd_1 \in H\}_{k=0}^{x_1; x_1 \geq 1}.
\]
Let us consider the residual set
\[
G_2 = H \setminus \{x_1 + kd_1 \in H\}_{k=0}^{x_1; x_1 \geq 1}.
\]
Then we can partition the sequence \( H\) in the following way
\[
H = G_1 \cup G_2.
\]
If \( G_2\) is still dense then we can repeat this process and obtain further a partition of \( H\) into three subsequence
\[
H = G_1 \cup G_2 \cup G_3.
\]
By induction, we can partition the sequence \( H\) in the following way
\[
H = \bigcup_{i=1}^{m} G_i \cup T
\]
where
\[
\lim_{n \to \infty} \frac{|T \cap N_n|}{n} = 0
\]
and \( J = \bigcup_{i=1}^{m} G_i\) with \( D(J) = D(H)\), since \( J \cap T = \emptyset\) and \( G_i = \{x_i + kd_i \in H\}_{k=0}^{x_i; x_i \geq 1}\).
Now it suffices to work with the corresponding points on the CoP \( C(n, H)\). Since by assumption \( C(n, H) \neq \emptyset\), It follows that there exist some axes \( L[a_i; \ell_i] \in C(n, H)\). Now let us suppose that
\[
[b] \notin \bigcup_{i=1}^{m} \{[x_i + kd_i] \in C(n, H)\}_{k=0}^{x_i; x_i \geq 1}
\]
for \( b \in \mathbb{H} \), then it follows that no two adjacent chords of equal length joining points in
\[
\bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; \geq 1}
\]
contains the point \([b]\). Let us suppose on the contrary that
\[
[a] \in \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; \geq 1}
\]
then it follows that \([a] \in \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; \geq 1} \) for some \( 1 \leq i \leq m \). We consider two cases. The case \([a]\) is a degenerate point in the set and the case it is non-degenerate point in the set. If \([a]\) is a degenerate point in the set \( \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; \geq 1} \), in particular, \([a]\) is the first point in the set. Then it follows that the following points
\([a], [x_i + d_i], [x_i + 2d_i], \ldots [x_i + sd_i]\)
are equally spaced with \( b = n - x_i \). It follows that \( b \) is contained in the arithmetic progression
\[
n - x_i, n - x_i - d_i, \ldots, n - x_i - sd_i
\]
which contradicts the assumption that \([b]\) cannot lie on at least one of any two adjacent chords of equal length. Otherwise
\[
n - x_i, n - x_i - d_i, \ldots, n - x_i - sd_i \in \left( \mathbb{N} \setminus \mathbb{J} \right) \cap \mathbb{N}_n
\]
and it follows each element in the weight set \( \mathbb{J} \cap \mathbb{N}_n = \mathbb{K} \) of the corresponding point set \( \mathbb{K}^* = \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; \geq 1} \) uniquely generates an element in the set \( \left( \mathbb{N} \setminus \mathbb{J} \right) \cap \mathbb{N}_n \), so that
\[
|\mathbb{J} \cap \mathbb{N}_n| \leq |\left( \mathbb{N} \setminus \mathbb{J} \right) \cap \mathbb{N}_n|.
\]
It follows that
\[
\mathcal{D}(\mathbb{N} \setminus \mathbb{H}) < \mathcal{D}(\mathbb{H})
\]
\[
= \mathcal{D}(\mathbb{J})
\]
\[
\leq \mathcal{D}(\mathbb{N} \setminus \mathbb{J})
\]
so that we have the inequality \( \mathcal{D}(\mathbb{N} \setminus \mathbb{H}) < \mathcal{D}(\mathbb{N} \setminus \mathbb{J}) \). This contradicts the equality under equality \( \mathcal{D}(\mathbb{H}) = \mathcal{D}(\mathbb{J}) \)
\[
\mathcal{D}(\mathbb{N} \setminus \mathbb{H}) = 1 - \mathcal{D}(\mathbb{H})
\]
\[
= 1 - \mathcal{D}(\mathbb{J})
\]
\[
= \mathcal{D}(\mathbb{N} \setminus \mathbb{J}).
\]
For the case \([a] = [x_i + sd_i]\), then we obtain the a priori arithmetic progression with \( b = n - x_i - sd_i \). The corresponding point \([b]\) also violates the required specification. If the point \([a] \in \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; \geq 1} \) is a non-degenerate
point, then \( a = x_i + jd_i \) for some \( 0 < j < s \). The same analysis can be carried out to yield a contradiction. Now for the case

\[
[a] \in \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1}
\]

then we choose the dilation \( \delta_r \) with \( r = d_j \) such that \( [b] \in \{ [x_j + kd_j] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1} \) for \( r < 0 \) if \( [b] \) is the last degenerate point in the set and \( r > 0 \) if \( [b] \) is the first degenerate point or a non-degenerate point in the set, so that we have

\[
L_{[a], [b + d_j]} \in \mathcal{C}(n + d_j, \mathbb{H}).
\]

This completes the first part of the proof. For the second part let us assume that for the axis \( L_{[a], [b]} \) of \( \mathcal{C}(n, \mathbb{H}) \), then

\[
[a] \notin \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1}
\]

then it must necessarily be that

\[
[a] \in \mathbb{T}_n^*
\]

where \( \mathbb{T}_n^* \) is the corresponding point set of elements in \( \mathbb{T} \cap \mathbb{N}_n \). Since

\[
|\mathbb{T}_n^*| \leq \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1},
\]

there exists some rotation \( \varpi_t \) such that the point \( \varpi_t([a]) \in \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1} \). In particular

\[
\varpi_t([a]) \in \{ [x_j + kd_j] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1}
\]

for some \( 1 \leq j \leq m \). It follows there must exist a point

\[
[v] \in \bigcup_{i=1}^{m} \{ [x_i + kd_i] \in \mathcal{C}(n, \mathbb{H}) \}_{k=0}^{s_i; s_i \geq 1}
\]

such that \( L_{[v], [\varpi_t([a])]} \) is an axis of the CoP \( \mathcal{C}(n, \mathbb{H}) \), by virtue of the previous arguments. Otherwise, we discard this choice of point and scout for a point with such property by varying the scale of the rotation \( \varpi_t \). The proof is completed by choosing the dilation \( \delta_r \) such that \( r = d_j \) for \( r < 0 \) if \( \varpi_t([a]) \) is the last degenerate point in the set and \( r > 0 \) if \( \varpi_t([a]) \) is the first degenerate point or a non-degenerate point in the set, so that \( L_{[v], ||\varpi_t([a])|| + d_j} \) is an axis of the CoP \( \mathcal{C}(n + d_j, \mathbb{H}) \).

\[\square\]

**Theorem 6.11.** There are infinitely many \( n \in \mathbb{M}_{a,d} \) with fixed \( a, d \in \mathbb{N} \) such that the representation

\[
n = z_1 + z_2
\]

where \( \mu(z_1) = \mu(z_2) \neq 0, z_1, z_2 \in \mathbb{N} \) and \( \mu \) is the Möbius function defined as

\[
\mu(m) = \begin{cases} 
1 & \text{if } m = 1 \\
0 & \text{if } p^k|m, k \in \mathbb{N} \setminus \{1\} \\
(-1)^r & \text{if } m = p_1p_2\cdots p_r
\end{cases}
\]
is valid.

Proof. The set of square-free integers

\[ Q := \{ m \in \mathbb{N} : \mu(m) \neq 0 \} \]

has natural density \( \frac{6}{\pi^2} \). For \( n \) large enough there exists some fixed \( N_0 > n \) such that the representation is valid

\[ N_o = z_1 + z_2 \]

with \( \mu(z_1), \mu(z_2) \neq 0 \). Invoking Theorem 6.10 there exist some \( t \in \mathbb{N} \) such that the representation is valid

\[ N_t := N_o + t = v_1 + v_2 \]

with \( \mu(v_1) = \mu(v_2) \neq 0 \). The result follows by an upwards induction in this manner. \( \square \)

Corollary 6.12. There are infinitely many \( n \in M_{a,d} \) with fixed \( a, d \in \mathbb{N} \) such that the representation

\[ n = z_1 + z_2 \]

with \( \gcd(z_1, z_2) = 1 \) and \( z_1, z_2 \in \mathbb{N} \) is valid.

Proof. The set

\[ R := \{ (m, n) : \gcd(m, k) = 1, 1 \leq m < k \} \]

has natural density \( D(R) = \frac{6}{\pi^2} \) with relatively small density for the residual set \( [2] \). The result follows by adapting a similar reasoning in Theorem 6.11. \( \square \)

Let be

\[ Q_p := \{ q \in \mathbb{N} \mid (q, P(p)) = 1 \} \quad (6.2) \]

with \( p \in \mathbb{P} \) and \( P(p) := \prod_{i=1}^{\pi(p)} p_i \).

Theorem 6.13. The set \( Q_p \) has for every \( p \in \mathbb{P} \) a positive density

\[ D(Q_p) = \lim_{n \to \infty} \frac{|Q_p \cap [N_n]|}{n} > 0. \]

Proof. Let us consider the set \( Q_p \) as result of the sieve of Eratosthenes. Each prime \( p_i \mid i = 1, \ldots, \pi(p) = p \) sieves in each interval with a length of \( p_i \) exactly one number. Then remain unsieved from \( N_{P(p)} \) exactly

\[ P(p) \cdot \prod_{i=1}^{\pi(p)} (p_i - 1) \]

numbers. Therefore \( Q_p \) has in \( N_{P(p)} \) a density

\[ \alpha(p) := \prod_{i=1}^{\pi(p)} \frac{(p_i - 1)}{P(p)} = \prod_{i=1}^{\pi(p)} \frac{p_i - 1}{p_i} > 0. \]
Then is (for $n$ large enough)
\[ |Q_p \cap \mathbb{N}_n| \sim n \cdot \alpha(p) \]
which means
\[ \mathcal{D}(Q_p) = \lim_{n \to \infty} n \cdot \alpha(p) = \alpha(p) > 0. \]

6.1. Application of density of points to partitions. In this section we explore the connection between the notion of density of points in a typical CoP to the possibility of partitioning number into certain sequences. This method tends to work very efficiently for sets of integers having a positive density.

**Theorem 6.14.** Let $\mathbb{H} \subset \mathbb{N}$ such that $\mathcal{D}(\mathbb{H}) > \frac{1}{2}$. Then every sufficiently large $n \in \mathbb{N}$ has representation of the form
\[ n = z_1 + z_2 \]
where $z_1, z_2 \in \mathbb{H}$.

**Proof.** Appealing to Proposition 6.4 we can write
\[ \lim_{n \to \infty} \frac{|\mathbb{H} \cap \mathbb{N}_n|}{\frac{n}{2}} \leq \mathcal{D}(\mathbb{H}_C(\infty)) \leq \lim_{n \to \infty} \frac{|\mathbb{H} \cap \mathbb{N}_n|}{\frac{n}{2}}. \]
By the uniqueness of the axes of CoPs we can write
\[ \# \{L(x,x) \in C(n) \mid \{x,y\} \cap \mathbb{H} \neq \emptyset\} = \nu(n,\mathbb{H}) + \# \{L(x,x) \in C(n) \mid x \in \mathbb{H}, y \in \mathbb{N} \setminus \mathbb{H}\}. \]
Let us assume $\nu(n,\mathbb{H}) = 0$ then it follows by appealing to Definition 6.2
\[ \mathcal{D}(\mathbb{H}_C(\infty)) = 2\mathcal{D}(\mathbb{H}) \]
\[ > 2 \times \frac{1}{2} = 1. \]
This contradicts the inequality $\mathcal{D}(\mathbb{H}_C(\infty)) \leq 1$ in Proposition 6.5. This proves that $\nu(n,\mathbb{H}) > 0$ for all sufficiently large values of $n \in \mathbb{N}$. □

**Corollary 6.15.** Let $\mathbb{R} := \{m \in \mathbb{N} \mid \mu(m) \neq 0\}$. Then every sufficiently large $n \in \mathbb{N}$ can be written in the form
\[ n = z_1 + z_2 \]
where $\mu(z_1) = \mu(z_2) \neq 0$.

**Proof.** By the uniqueness of the axes of CoPs we can write
\[ \# \{L(x,x) \in C(n) \mid \{x,y\} \cap \mathbb{R} \neq \emptyset\} = \nu(n,\mathbb{R}) + \# \{L(x,x) \in C(n) \mid x \in \mathbb{R}, y \in \mathbb{N} \setminus \mathbb{R}\}. \]
Let us assume $\nu(n,\mathbb{R}) = 0$ then it follows by appealing to Definition 6.2 and Theorem 6.14
\[ \mathcal{D}(\mathbb{R}_C(\infty)) = 2\mathcal{D}(\mathbb{R}) \]
\[ = \frac{12}{\pi^2} > 1 \]
since $\mathcal{D}(\mathbb{R}) = \frac{6}{\pi^2}$. This contradicts the inequality $\mathcal{D}(\mathbb{R}_C(\infty)) \leq 1$ in Proposition 6.5. This proves that $\nu(n,\mathbb{R}) > 0$ for all sufficiently large values of $n \in \mathbb{N}$. □
One could ever hope and dream of this strategy to work when we replace the set \( \mathbb{R} \) of square-free integers with the set of prime numbers. There we would certainly run into complete deadlock, since the prime in accordance with the prime number theorem have density zero. Any success in this regard could conceivably work by introducing some exotic forms of the notion of density of points and carefully choosing a subset of the integers that is somewhat dense among the set of integers and covers that primes. We propose a strategy somewhat akin to the above method for possibly getting a handle on the binary Goldbach conjecture and its variants. Before that we state and prove a conditional theorem concerning the binary Goldbach conjecture.

**Theorem 6.16.** Let \( \mathbb{B} \subset \mathbb{N} \) such that \( \mathbb{P} \subset \mathbb{B} \) with \( |C(n, \mathbb{B})| = |\mathbb{B} \cap \mathbb{N}_n| \) for all \( n \in \mathbb{N} \) so that

\[
\lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} > \frac{1}{2}
\]

where \( \eta(n) \) is the counting function of all integers belonging to the set \( \mathbb{B} \cap \mathbb{N}_n \). Then \( \nu(n, \mathbb{P}) > 0 \) for all sufficiently large values of \( n \in 2\mathbb{N} \).

**Proof.** First let us upper and lower bound the density of points in the CoP \( C(n, \mathbb{B}) \) belonging to the set of the primes \( \mathbb{P} \) so that under the condition \( |C(n, \mathbb{B})| = |\mathbb{B} \cap \mathbb{N}_n| \) for all \( n \in \mathbb{N} \), we obtain the inequality

\[
\lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} 
\leq \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)-1}
\leq \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)-2}
\leq \frac{2}{\eta(n)}
\]

Appealing to the uniqueness of the axes of CoPs, we can write

\[
\# \left\{ L_{\{x,y\}} \in C(n, \mathbb{B}) \setminus \mathbb{P} \neq 0 \right\} = \nu(n, \mathbb{P}) + \# \left\{ L_{\{x,y\}} \in C(n, \mathbb{B}) \setminus \mathbb{P} \right\}
\]

Let us assume to the contrary \( \nu(n, \mathbb{P}) = 0 \), then it follows that no two points in the CoP \( C(n, \mathbb{B}) \) with weight in the set \( \mathbb{P} \) are axes partners, so that under the requirement

\[
\lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} > \frac{1}{2}
\]

where \( \eta(n) \) is the counting function of all integers belonging to the set \( \mathbb{B} \cap \mathbb{N}_n \), we obtain the inequality

\[
\mathcal{D}(\mathbb{P}_{C(\infty, \mathbb{B})}) = \frac{2}{\lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)}}
\]

\[
> 2 \times \frac{1}{2} = 1.
\]

This contradicts the inequality \( \mathcal{D}(\mathbb{P}_{C(\infty, \mathbb{B})}) \leq 1 \) in Proposition 6.5. This proves that \( \nu(n, \mathbb{P}) > 0 \) for all sufficiently large values of \( n \in 2\mathbb{N} \).

**6.2. Binary Goldbach conjecture proof technique via circles of partition.**

In this subsection we propose series of steps that could be taken to confirm the truth of the binary Goldbach conjecture. We enumerate the strategies chronologically as follows:
• First construct a subset of the integers $\mathbb{B}$ that covers the primes with $|C(n, \mathbb{B})| = |\mathbb{B} \cap \mathbb{N}|$ for all $n \in \mathbb{N}$ so that

$$\lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} > \frac{1}{2}$$

where $\eta(n)$ is the counting function of all integers belonging to the set $\mathbb{B} \cap \mathbb{N}_n$.

• Next we remark that the following inequality also hold and this can be obtain by replacing the set $\mathbb{N}$ with the set $\mathbb{B}$

$$\lim_{n \to \infty} \left\lfloor \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} \right\rfloor \leq D(P_{C(\infty, \mathbb{B})}) \leq \lim_{n \to \infty} \left\lfloor \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} \right\rfloor = 2 \lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)}.$$

• Appealing to the uniqueness of the axes of CoPs, we can write

$$\# \{L_{[x], [y]} \in C(n, \mathbb{B}) | \{x, y\} \cap \mathbb{P} \neq \emptyset\} = \nu(n, \mathbb{P}) + \# \{L_{[x], [y]} \in C(n, \mathbb{B}) | x \in \mathbb{P}, \ y \in \mathbb{B} \setminus \mathbb{P}\}.$$

• Let us assume $\nu(n, \mathbb{P}) = 0$ then it follows by appealing to Definition 6.2

$$D(P_{C(\infty, \mathbb{B})}) = 2 \lim_{n \to \infty} \frac{|\mathbb{P} \cap \mathbb{N}_n|}{\eta(n)} > 2 \times \frac{1}{2} = 1.$$

This contradicts the inequality $D(P_{C(\infty, \mathbb{B})}) \leq 1$ in Proposition 6.5. This proves that $\nu(n, \mathbb{P}) > 0$ for all sufficiently large values of $n \in 2\mathbb{N}$.

### 7. Open and Connected Circles of Partition

In this section we introduce the notion of open CoP. We first launch the notion of a path connecting CoP and examine in-depth the concept of connected CoPs and their interplay with other notions launched thus far. Also here and in the following sections only real axes are considered, the attribute real is not used.

**Definition 7.1.** Let $M \subseteq \mathbb{N}$ with $C(n, M) \neq \emptyset$ and $C(s, M) \neq \emptyset$ be any two distinct CoPs. Then by the path joining the CoP $C(n, M)$ to the CoP $C(s, M)$ we mean the line joining $[x] \in C(n, M)$ to $[y] \in C(s, M)$, denoted as $L_{[x], [y]}$, such that $L_{[x], [y]}$ is an axis of the CoP $C(s, M)$

$$L_{[x], [y]} = L_{[x], [y]} \in C(s, M).$$

We say the CoP $C(n, M)$ is connected to the CoP $C(s, M)$ if there exists such a path.

We say the CoP $C(n, M)$ is **strongly connected** to some CoP $C(m, M)$ if the connection exists for all possible dilations

$$\delta_r : C(n, M) \to C(s, M) \text{ by } s = n + r.$$

with $\delta_r([x]) = [y]$. We say the CoP $C(n, M)$ is fully connected to the CoP $C(s, M)$ if there exists such a path for each $[x] \in C(n, M)$.
Proposition 7.2. Let \( M \subseteq N \) with \( C(n, M) \neq \emptyset \) and \( C(s, M) \neq \emptyset \) be any two distinct CoPs with a common point \([x]\). Then and only then \( C(n, M) \) is connected to \( C(s, M) \).

Proof. Since \([x] \in C(s, M)\) there must be an axis \( L_{[x],[s-x]} \in C(s, M)\). Since \([x] \in C(n, M)\) there exists the path \( L_{[x],[s-x]} \). Hence \( C(n, M) \) is connected to \( C(s, M) \).

If otherwise there exists such a path \( L_{[x],[y]}\) with a fixed \([x] \in C(n, M)\) and any \([y] \in C(s, M)\) such that \( L_{[x],[y]} \in C(s, M)\) then it must certainly be that \([y] = [s-x]\) and \([x]\) is also a point of \( C(n, M)\). \(\square\)

Proposition 7.3. Let \( M \subseteq N \) and \( C(n, M) \) be a CoP. If \( C(n, M) \) is fully connected to \( C(s, M) \) then

\[
C(n, M) \subseteq C(s, M).
\]

Proof. Let \( M \subseteq N \) and suppose the CoP \( C(n, M) \) is connected to the CoP \( C(s, M) \) then for each point \([x] \in C(n, M)\) there exists an axis \( L_{[x],[y]} \in C(s, M)\) for some \([y] \in C(s, M)\). It follows that \([x] \in C(s, M)\), thereby ending the proof since the point \([x]\) is an arbitrary point in the CoP \( C(n, M)\). \(\square\)

Theorem 7.4. Let \( M \subseteq N \) and \( C(n, M) \) be any CoP admits aligned embedding. Then \( C(n, M) \) is strongly connected to some CoP \( C(m,M) \) admits aligned embedding.

Proof. We assume that \( C(n, M) \) is not strongly connected to any \( C(m, M) \), by virtue of the definition. Invoking the virtue the CoPs admit aligned embedding, we can assume \( C(n, M) \subseteq C(s, M) \). The line \( L_{[x],[n-x]} \) is an axis of \( C(n, M) \) for any \([x] \in C(n, M)\). It follows that \( L_{[x],[s-x]} \) is also an axis of the CoP \( C(s, M) \). Since no two CoPs are strongly connected and because of Theorem 3.11 there exists some dilation \( \delta_{r_1} : C(n, M) \rightarrow C(s, M) \) such that \([s-x] \neq \delta_{r_1}([x])\) for each \([x] \in C(n, M)\).

Let us produce a line \( L_{[x],[\delta_{r_1}([x])]}\) by joining \([x]\) to \( \delta_{r_1}([x])\). Now, we can certainly partition these lines as axes of large and small CoPs relative to the CoP \( C(s) \) as below

\[
\{L_{[x],[\delta_{r_1}([x])]} \in C(v, M)\mid n < v \leq s - 1\} \cup \{L_{[x],[\delta_{r_1}([x])]} \in C(k, M)\mid k > s\}
\]

Let us now pick arbitrarily a small CoP relative to the CoP \( C(s, M) \) and large relative to the CoP \( C(n, M) \). That is we pick a CoP \( C(v, M) \) from the first set arbitrarily. Then we obtain the strict embedding

\[
C(n, M) \subset C(v, M) \subset C(s, M).
\]

Otherwise the CoP \( C(n, M) \) will have the axis \( L_{[x],[\delta_{r_1}([x])]}\), which will contradict our assumption. Under the assumption that no two CoPs are strongly connected, it follows that there exist some dilation

\[
\delta_{r_2} : C(n, M) \rightarrow C(v, M)
\]

such that for each \([x] \in C(n, M)\) then \( \delta_{r_2}([x]) \neq [v-x]\). By repeating the argument in this manner under the assumption that no two CoPs are connected we obtain the following infinite embedding into the CoP \( C(n, M) \) as follows

\[
C(n, M) \subset \cdots \subset C(t, M) \subset C(v, M) \subset C(s, M)
\]
and we have the following infinite descending sequence of generators toward the generator \( n \)
\[
n < \cdots < t < v < s.
\]
This is absurd, thereby ending the proof of the claim. \( \square \)

Corollary 7.5. Let \( C(n, M) \) and \( C(m, M) \) be two CoPs admit aligned embedding. If holds \( n < m \) then \( C(n, M) \) is fully connected to the CoP \( C(m, M) \).

Proof. Due to Theorem 7.4 holds
\[
C(n, M) \subset C(m, M).
\]
Hence each point of \( C(n, M) \) is also a point of \( C(m, M) \). Because of Proposition 7.2 it follows that \( C(n, M) \) is connected to \( C(m, M) \) for each point \( [x] \in C(n, M) \). Hence \( C(n, M) \) is fully connected to \( C(m, M) \). \( \square \)

One could imagine an analogous results of fully connected CoPs if we take the base set \( \mathbb{N} \) to be the set \( \mathbb{P} \) of prime numbers. There things become a lot more complicated and will require a careful analysis of the situation. But this endeavour is not far from reach by examining additional concept that are somewhat on par with the subtleties and properties of these sequence. To that end, we make the following conjecture.

Conjecture 7.6. There are infinitely many pairs of fully connected CoPs of the form \( C(n, \mathbb{P}) \).

Definition 7.7. Let \( \mathbb{M} \subseteq \mathbb{N} \) and \( C(n, M) \) be a CoP with \( L_{[x],[y]} \in C(n, M) \). Then by the open CoP induced by the point \( [x],[y] \), we mean the exclusion \( C(n, M) \setminus [x],[y] \). We call the points \( [x],[y] \) the gates to the interior of the open CoP. We denote the induced open CoP by \( C(n, M)[x],[y] \subseteq C(n, M) \). We say the CoPs \( C(s, M) \) and \( C(n, M) \) forms a two-member community if and only if there is a path joining the gate \( [x],[y] \) of \( C(n, M)[x],[y] \) to the CoP \( C(s, M) \).

8. Children, Offspring and Family Induced by Circles of Partition

In this section we introduce the notion of children, the offspring and the family induced by a typical CoP. We relate this notion to the notion of connected CoPs.

Definition 8.1. Let \( \mathbb{M} \subseteq \mathbb{N} \) and \( C(n, M) \neq \emptyset \) and let \( \{L_{[u_i],[v_i]}\}_{i=1}^{N;N \geq 2} \) for some \( N \geq 2 \) be the set of all the axes. Then we say the CoP \( C(s, M) \) is a **Child** of the CoP \( C(n, M) \) if there exist some axes \( L_{[u_i],[v_i]} \in \{L_{[u_i],[v_i]}\}_{i=1}^{N;N \geq 2} \) such that at least one of \( L_{[u_i],[u_j]} \), \( L_{[v_i],[v_j]} \), \( L_{[u_i],[v_i]} \), \( L_{[v_i],[u_j]} \) is an axis of the child CoP \( C(s, M) \). This axis forms the **principal axis** of the child CoP. We call the collection of all CoPs generated in this manner the **offspring** of the **parent** CoP \( C(n, M) \). The parent CoP \( C(n, M) \) together with its offspring forms a **complete family** of CoPs. The size of the family of CoPs is the number of CoPs in the family. A subset of a family is said to be an **incomplete family** of CoPs.
Example 8.2. Let us consider the CoP with $\|C(20, P)\| = \{3, 7, 13, 17\}$ with axes $L_{[3],[7]}$ and $L_{[7],[13]}$. We consider the following chords $L_{[3],[7]}, L_{[3],[13]}, L_{[7],[17]}, L_{[13],[17]}$. These chords correspond as principal axes to the following CoPs $C(10, P), C(16, P), C(24, P), C(30, P)$. Hence we obtain a complete family of CoPs of size 5.

Proposition 8.3. Let $C(n, M)$ a non-empty CoP. Then each axis point $[x]$ together with a point $[u]$ of another axis of $C(n, M)$ generates a child $C(s, M)$ of the parent $C(n, M)$ with $s = \|[x]\| + \|[u]\|$.

Proof. Let $L_{[x],[u]}$ and $L_{[u],[v]}$ be two axes of $C(n, M)$. Appealing to Proposition 8.5 we have

$$\|[x]\| + \|[u]\| = s \neq n.$$ 

Hence $[x]$ and $[u]$ form the axis $L_{[x],[u]} \in C(s, M)$ and $C(s, M)$ is a child of $C(n, M)$. □

Proposition 8.4. Let $n \in \mathbb{N}, M \subseteq \mathbb{N}$ and $C(n, M)$ be a CoP admitting aligned embedding. If holds $|C(n, M)| \geq 4$ then the CoP $C(n, M)$ admits an infinite chain of its descendants.

Proof. Due to $|C(n, M)| \geq 4$ there is an axis point $[u] \in C(n, M)$ with

$$u > \min (\|[w]\| \mid [w] \in C(n, M))$$

and a point $[v] \in C(n, M)$ of another axis with $u + v = m > n$. It follows that there exists an axis $L_{[u],[v]} \in C(m, M)$. Ergo holds $[u] \in C(m, M)$. Appealing to Proposition 8.3 the CoP $C(m, M)$ is a child of the CoP $C(n, M)$. Since $m > n$ and $C(n, M)$ admits aligned embedding, it holds

$$C(n, M) \subset C(m, M).$$

Now we choose a point $[w]$ of $C(m, M)$ and the latter changes its role to be a parent. With the same procedure as above we produce an axis $L_{[u],[w]} \in C(r, M)$ with $[u], [w] \in C(r, M)$ and

$$C(n, M) \subset C(m, M) \subset C(r, M).$$

This procedure can be repeated infinitely many often. We obtain an infinite chain of descendants of the CoP $C(n, M)$ as its prime father. □

Proposition 8.5. Let $M \subseteq \mathbb{N}$ and $C(n, M)$ be a parent of a complete family. Then $C(n, M)$ partitions the offspring into two incomplete families of equal sizes.

Proof. In virtue of Proposition 8.3 two points of distinct axes of the CoP $C(n, M)$ generates a child of it. Let $L_{[u],[v]}, L_{[x],[y]} \mid u < x$ two arbitrary axes of $C(n, M)$. Because $[u], [v]$ and $[x], [y]$ are axis points holds

$$n = u + v = x + y$$

and therefore

$$v = x - u + y$$

because of $x > u$

$$v > y$$
Hence we get
\[ u < x < y < v \] and therefore
\[ s_1 := u + x < s_2 := u + y < n = x + y \] and
\[ t_1 := v + y > t_2 := v + x > n = v + u \]
and a chain of children
\[ C(s_1, M), C(s_2, M), C(n, M), C(t_2, M), C(t_1, M) \] with
\[ s_1 < s_2 < n < t_2 < t_1. \]
Therefore holds that for all two axes 4 children are generated, two on the left side of \( C(n, M) \) and two on the right side in a chain of children. Because \( C(n, M) \) for all two axes is located in the middle of the chain, the parent CoP \( C(n, M) \) partitions its offspring in two halves, the incomplete families of equal sizes. □

**Proposition 8.6.** If the parent CoP admits embedding then their children admit aligned embedding.

**Proof.** We look at the last proof and choose \([u]\) as the first point of the parent CoP \( C(n, M) \)
\[ u := \min (w \in \|C(n, M)\|). \]
Then holds
\[ [u] \in C(s_1, M) \] and \([u] \in C(s_2, M) \]
\[ \max (w \in \|C(s_1, M)\|) = x < y = \max (w \in \|C(s_2, M)\|) \]
and hence
\[ C(s_1, M) \subset C(s_2, M) \] under \( s_1 < s_2. \)
Because \( C(n, M) \) admits embedding holds
\[ C(s_1, M) \subset C(s_2, M) \subset C(n, M) \subset C(t_2, M) \subset C(t_1, M) \] under
\[ s_1 < s_2 < n < t_2 < t_1. \]
□

**Corollary 8.7.** If the CoP \( C(n, M) \) admits embedding and has \( 2k \) children, then it follows by virtue of Propositions 8.5 and 8.6 for its complete family
\[ C(s_1, M) \subset \ldots \subset C(s_k, M) \subset C(n, M) \subset C(t_k, M) \subset \ldots \subset C(t_1, M) \]
and we have the following symmetry
\[ s_2 - s_1 = t_1 - t_2, \ldots, s_k - s_{k-1} = t_{k-1} - t_k, n - s_k = t_k - n. \]

**Proof.** The embedding chain is a direct consequence of the Propositions 8.5 and 8.6.

Now we prove the symmetry of the differences of the children generators. We look again at the proof of Proposition 8.6 with
\[ u < x < y < v \] and therefore
\[ s_1 := u + x < s_2 := u + y < n = x + y \] and
\[ t_1 := v + y > t_2 := v + x > n = v + u \]
for two arbitrary axes \( L_{[u], [v]} \), \( L_{[x], [y]} \) of \( C(n, M) \). Then is
\[ s_1 < s_2 < n < t_2 < t_1 \]
and we get
\[ s_2 - s_1 = u + y - u - x = y - x \quad \text{and} \quad n - s_2 = x + y - u - y = x - u \]
\[ t_1 - t_2 = v + y - v - x = y - x \quad \text{and} \quad t_2 - n = v + x - v - u = x - u. \]
Because the two axes are arbitrary this symmetry around the generator \( n \) holds for all axes. From this follows the claim.

\[ \square \]

**Theorem 8.8.** Let \( M \subseteq N \) and \( C(n, M) \) be a CoP with \( |C(n, M)| = k \). Then the number of children in the family with parent \( C(n, M) \) satisfies the upper bound

\[ \leq 2 \left\lfloor \frac{k}{2} \right\rfloor \left( \left\lfloor \frac{k}{2} \right\rfloor - 1 \right) \]

and the lower bound

\[ \geq 2 (n_a - 2) = 4 \left( \left\lfloor \frac{k}{2} \right\rfloor - 1 \right) \text{ with } n_a = 2 \left\lfloor \frac{k}{2} \right\rfloor. \]

**Proof.** At first we prove the upper bound. The CoP \( C(n, M) \) with \( |C(n, M)| = k \) contains \( \left\lfloor \frac{k}{2} \right\rfloor \) different axes. Each axis contains two points of the parent \( C(n, M) \) and determines children with at most \( \left\lfloor \frac{k}{2} \right\rfloor - 1 \) number of axes. The upper bound follows from this counting argument.

Now we prove the lower bound. In virtue of Corollary 2.7 the weights of the points of \( C(n, M) \) are strictly totally ordered. Now we remove from this sequence the weight of the center if it exists. It remains \( n_a = 2 \left\lfloor \frac{k}{2} \right\rfloor \) weights. We enumerate them as

\[ x_1 < x_2 < \ldots < x_{n_a - 1} < x_{n_a} \]

and form the following sequences

\[ s_1 := x_1 + x_2 < s_2 := x_1 + x_3 < \ldots < s_{n_a - 2} := x_1 + x_{n_a - 1} < x_1 + x_{n_a} = n \]

and

\[ t_1 := x_{n_a} + x_{n_a - 1} > t_2 := x_{n_a} + x_{n_a - 2} > \ldots > t_{n_a - 2} := x_{n_a} + x_2 > x_{n_a} + x_1 = n. \]

Hence we obtain

\[ s_1 < \ldots < s_{n_a - 2} < n < t_{n_a - 2} < \ldots < t_1 \]

and have at least \( 2(n_a - 2) \) different generators for children of \( C(n, M) \). \[ \square \]

**Remark 8.9.** We observe that if a CoP contains not more than 3 points then the CoP has no children. We call these CoPs **childless**. And if a CoP has two axes then the CoP has 4 children. Therefore there are no CoPs with only one child or only two or three children.

**Proposition 8.10.** Let \( M \subseteq N \). There is no parent CoP \( C(n, M) \) admitting embedding with \( |C(n, M)| \geq 4 \) such that all its children are childless.

**Proof.** Because of Proposition 8.9 the children admit aligned embedding. And since the parent CoP has at least 4 children there are because of Proposition 8.5 at least 2 children with generators > \( n \). Because the children admit aligned embedding then holds for a child \( C(s, M) \) with \( s > n \)

\[ C(s, M) \supset C(n, M) \quad \text{and therefore} \quad |C(s, M)| > |C(n, M)| \geq 4. \]

Hence there are at least two children with more than 4 own children and hence not childless. \[ \square \]
Remark 8.11. Next we launch an important result that will certainly have significant offshoots throughout our studies. Very roughly, it tells us that we can always partition any complete family into incomplete families with equal dilation between the members.

Lemma 8.12 (Regularity lemma). The offspring of a CoP $C(n, M)$ can be partitioned into incomplete families with equal scale dilation between sequence of successive embedding.

Proof. If there exist no embedding among the children of the parent $C(n, M)$, then obviously we have a partition into a one member incomplete family and the dilation in each family is trivial. Let us assume $C(s_1, M) \subset C(s_2, M) \subset \ldots \subset C(s_k, M)$ for $k \geq 2$ be a sequence of children of the parent $C(n, M)$ with equal scale dilation between successive embedding. If the sequence is all of the children of the parent $C(n, M)$ then the parent must be inserted in virtue of Corollary 8.7 in the middle of the offset chain. Now let us remove from the chain the parent $C(n, M)$ with the two closest children. Then we obtain a partition of collection of children in the embedding into two sub-chains of embedding with equal scale dilation between successive children, those to the left of the children closest to the parent $C(n, M)$ and to the right of the children closest to the parent $C(n, M)$. For the sequence removed from the a priori sequence of children given below

$$C(s_i, M) \subset C(n, M) \subset C(s_{i+1}, M)$$

we remove the parent $C(n, M)$ and we obtain a third partition of offspring with equal scale dilation

$$C(s_i, M) \subset C(s_{i+1}, M).$$

For the case where not all children are contained in the a priori embedding, then we have already obtained a partition of collection of children into an incomplete family with equal scale dilation between successive members. The remaining collection of children can also be partitioned into incomplete families by choosing an embedding with equal scale dilation between successive children. □

Theorem 8.13. The number of pairs of connected children in any complete family is lower bounded by

$$\geq \frac{n_a(n_a - 2)(n_a - 3)}{2} = 2 \left\lfloor \frac{k}{2} \right\rfloor \left( \left\lfloor \frac{k}{2} \right\rfloor - 1 \right) (n_a - 3) \geq 2 \left\lfloor \frac{k}{2} \right\rfloor \left( \left\lfloor \frac{k}{2} \right\rfloor - 1 \right)$$

if the parent CoP has $n_a$ axis points and $n_a = 2 \left\lfloor \frac{k}{2} \right\rfloor > 3$.

Proof. In virtue of Proposition 7.2 two CoPs are connected if and only if they have a common point. And the children are generated by pairs of points on different axes. Each such point $[x]$ of the parent CoP occurs therefore in $n_a - 2$ children at least. Hence there are $(n_a - 2)(n_a - 3)$ pairs of children containing the point $[x]$. There are $n_a$ axis points. Therefore this number of pairs must be multiplied by $n_a$. This results the formula of the lower bound. □

In comparison with Theorem 8.8 we observe that the number of pairs of connected children of a complete family is always greater or equal to the number of its children. From the proof of Theorem 8.13 we see that each child is connected with another child of the same family.
Example 8.14. We take as parent CoP
\[ C(22, \mathbb{P}) = \{[3], [5], [11], [17], [19] \} \rightarrow k = 5, n_a = 4. \] In virtue of Theorem 9.1, it has maximal
\[ 2 \cdot 2 \cdot 1 = 4 \]
children and in virtue of Theorem 8.13 at least
\[ \frac{4 \cdot 2 \cdot 1}{2} = 4 \]
pairs of connected children. As children we get
\[ C(8, \mathbb{P}) = \{[3], [5]\} \]
\[ C(20, \mathbb{P}) = \{[3], [7], [13], [17]\} \]
\[ C(24, \mathbb{P}) = \{[5], [7], [11], [13], [17], [19]\} \]
\[ C(36, \mathbb{P}) = \{[5], [7], [13], [17], [19], [23], [29], [31]\}. \]
We see that [3] occurs in the children 2 times. With it there is 1 pair of children containing the point [3]. [5] occurs 3 times and is hence contained in 3 pairs. [17] occurs 3 times too and [19] occurs 2 times and is contained in 1 pair. All together we have \( \overline{8} > 6 \) pairs of connected children with respect to the points of the parent CoP. But we see that more than these points are common points in the offset. Hence there are 6 further pairs of connected children. The principal axes are marked as boldface.
The CoP \( C(24, \mathbb{P}) \) contains 6 axis points and has therefore at most 12 children with 36 pairs of connected children at least.

Theorem 8.15. Let \( \mathbb{M} \subseteq \mathbb{N} \) and \( C(n, \mathbb{M}), C(m, \mathbb{M}) \) be two CoPs and \( \hat{\mathcal{O}}_n, \hat{\mathcal{O}}_m \) their complete families. If \( |\hat{\mathcal{O}}_n| < |\hat{\mathcal{O}}_m| \) and there exists a child \( C(s, \mathbb{M}) \in \hat{\mathcal{O}}_n \) with \( C(s, \mathbb{M}) \notin \hat{\mathcal{O}}_m \) then holds
\[ C(n, \mathbb{M}) \not\subset C(m, \mathbb{M}) \text{ and } C(n, \mathbb{M}) \not\supset C(m, \mathbb{M}), \]
which means that these \( C(n, \mathbb{M}) \) and \( C(m, \mathbb{M}) \) not admit embedding.

Proof. Due to \( C(s, \mathbb{M}) \) is a child of \( C(n, \mathbb{M}) \) there are two points \([x], [u] \in C(n, \mathbb{M})\) with \( x + u = s \). Then is \( L_{[x], [u]} \) the principal axis of \( C(s, \mathbb{M}) \). And due to \( C(s, \mathbb{M}) \) is not a child of \( C(m, \mathbb{M}) \) there are no points in \( C(m, \mathbb{M}) \) with a weight sum equals \( s \). Therefore the points \([x], [u] \) belong not to \( C(m, \mathbb{M}) \). Hence holds \( C(n, \mathbb{M}) \not\subset C(m, \mathbb{M}) \). Because of \( |\hat{\mathcal{O}}_n| < |\hat{\mathcal{O}}_m| \) there is a child of \( C(m, \mathbb{M}) \) which is not a child of \( C(n, \mathbb{M}) \). Therefore holds \( C(n, \mathbb{M}) \not\supset C(m, \mathbb{M}) \).

Theorem 8.16. Let \( \mathbb{M} \subseteq \mathbb{N} \) and \( C(n, \mathbb{M}) \) and \( C(m, \mathbb{M}) \) be two CoPs admitting aligned embedding. Without loss of generality we assume
\[ C(n, \mathbb{M}) \subset C(m, \mathbb{M}). \]

Then \( C(n, \mathbb{M}) \) is a child of \( C(m, \mathbb{M}) \). If there is a chord \( L_{[x], [y]} \) of \( C(n, \mathbb{M}) \) with \( x + y = m \) then \( C(m, \mathbb{M}) \) is also a child of \( C(n, \mathbb{M}) \). Additionally the complete family \( \hat{\mathcal{O}}_n \) of \( C(n, \mathbb{M}) \) is a subset of the complete family \( \hat{\mathcal{O}}_m \) of \( C(m, \mathbb{M}) \).

Proof. Due to \( C(n, \mathbb{M}) \subset C(m, \mathbb{M}) \) by virtue of Definition 2.6 hold \( n < m \) and
\[ \min (x \mid [x] \in C(n, \mathbb{M})) = \min (u \mid [u] \in C(m, \mathbb{M})). \]
All chords $L_{[x],[y]}$ of $\mathcal{C}(n,M)$ are also chords of $\mathcal{C}(m,M)$ excluding the chords between points $[x],[y] \in \mathcal{C}(n,M)$ with $x + y = m$. By exploiting the underlying embedding, we notice that all chords of $\mathcal{C}(m,M)$ which are axes of $\mathcal{C}(n,M)$ generate all the same child, the CoP $\mathcal{C}(n,M)$. Hence the CoP $\mathcal{C}(n,M)$ is a child of the CoP $\mathcal{C}(m,M)$, and if there is no chord $L_{[x],[y]}$ of $\mathcal{C}(n,M)$ with $x + y = m$ then all children of $\mathcal{C}(n,M)$ are children of $\mathcal{C}(m,M)$ too. Hence the complete family $\hat{O}_n$ is a subset of the complete family $\hat{O}_m$ in this case.

If such a chord of $\mathcal{C}(n,M)$ exists then this chord is an axis of $\mathcal{C}(m,M)$, so that $\mathcal{C}(m,M)$ is a child of $\mathcal{C}(n,M)$. Because the parents belong to its complete family holds that the complete family $\hat{O}_n$ is a subset of $\hat{O}_m$ in this case too. \hfill \Box

9. Isomorphic Circles of Partition

In this section we introduce and study the notion of isomorphism between CoPs.

**Definition 9.1.** Let $M \subseteq N$ and let $\mathcal{C}(n,M)$ and $\mathcal{C}(m,M)$ be parents with the complete families $\hat{O}_n$ and $\hat{O}_m$, respectively. Then we say the parents $\mathcal{C}(n,M)$ and $\mathcal{C}(m,M)$ are isomorphic if

$$\hat{O}_m \cap \hat{O}_n \neq \emptyset.$$ 

We call the number $|\hat{O}_m \cap \hat{O}_n|$ the degree of isomorphism. We denote this isomorphism by $\mathcal{C}(n,M) \cong \mathcal{C}(m,M)$. We say the degree of isomorphism is high if at least one of the following equality holds

$$\frac{|\hat{O}_m \cap \hat{O}_n|}{|\hat{O}_n|} = 1$$

or

$$\frac{|\hat{O}_m \cap \hat{O}_n|}{|\hat{O}_m|} = 1.$$ 

Otherwise, we say the degree of isomorphism is low.

**Proposition 9.2.** Let $\mathcal{C}(n,M)$ and $\mathcal{C}(m,M)$ be two CoPs. If $\mathcal{C}(n,M)$ is connected to $\mathcal{C}(m,M)$ by at least three distinct paths then $\mathcal{C}(n,M) \cong \mathcal{C}(m,M)$.

**Proof.** First let us assume the CoPs $\mathcal{C}(n,M)$ is connected to the CoP $\mathcal{C}(m,M)$ by at least three distinct paths. Then it follows that there exist some distinct points $[x],[y],[z] \in \mathcal{C}(m,M)$ such that $L_{[x],[u]}, L_{[y],[v]}, L_{[z],[w]} \in \mathcal{C}(m,M)$. It follows that there exist at least the following chords $L_{[x],[y]}, L_{[x],[z]}, L_{[y],[z]} \in \mathcal{C}(m,M)$. It follows from the pigeonhole principle that at least one of the following lines $L_{[x],[y]}, L_{[x],[z]}, L_{[y],[z]}$ must be a chord of the CoP $\mathcal{C}(n,M)$. It follows that the families $\hat{O}_n \cap \hat{O}_m \neq \emptyset$. \hfill \Box

**Theorem 9.3.** Let $\mathcal{C}(n,M)$ and $\mathcal{C}(m,M)$ be two parent CoPs admitting aligned embedding. Then holds

$$\mathcal{C}(n,M) \cong \mathcal{C}(m,M)$$

with a high degree.
Proof. Without loss of generality let us assume that $C(n, \mathcal{M}) \subset C(m, \mathcal{M})$. Then by virtue of Theorem 8.16 all children of $C(n, \mathcal{M})$ are children of $C(m, \mathcal{M})$ too. Hence holds $\hat{\mathcal{O}}_n \subset \hat{\mathcal{O}}_m$ and therefore

\[ \frac{|\hat{\mathcal{O}}_n \cap \hat{\mathcal{O}}_m|}{|\hat{\mathcal{O}}_n|} = 1. \]

\[ \square \]

10. Compatible and Incompatible Circles of Partition

In this section we introduce the notion of compatibility and incompatibility of circles of partition. We launch the following formal language.

Definition 10.1. Let $\mathcal{M} \subseteq \mathbb{N}$ and $C(n, \mathcal{M})$ and $C(m, \mathcal{M})$ be any two CoPs. Then we say the CoPs $C(n, \mathcal{M})$ and $C(m, \mathcal{M})$ are compatible if there exists some CoP $C(r, \mathcal{M})$ satisfying $C(n, \mathcal{M}) \cup C(m, \mathcal{M}) \subseteq C(r, \mathcal{M})$ such that for each $x \in C(n, \mathcal{M}) \cup C(m, \mathcal{M})$ with $2x \neq n$ there exist some $y \in C(n, \mathcal{M}) \cup C(m, \mathcal{M})$ so that $L[x,y] \in C(r, \mathcal{M})$.

We denote the compatibility by $C(n, \mathcal{M}) \diamond C(m, \mathcal{M})$. We call the CoP $C(r, \mathcal{M})$ the cover of this compatibility.

Proposition 10.2. Let $C(n, \mathcal{M})$ and $C(m, \mathcal{M})$ be any two CoPs admitting aligned embedding. Then $C(n, \mathcal{M}) \diamond C(m, \mathcal{M})$.

Proof. W.l.o.g. we assume $C(n, \mathcal{M}) \subset C(m, \mathcal{M})$.

Then holds

$C(n, \mathcal{M}) \cup C(m, \mathcal{M}) = C(m, \mathcal{M})$ and therefore

$C(n, \mathcal{M}) \diamond C(m, \mathcal{M})$.

\[ \square \]

Theorem 10.3. Let $\mathcal{M} \subseteq \mathbb{N}$. Then there exists no CoPs of the forms $C(n, \mathcal{M})$ and $C(m, \mathcal{M})$ with all axes points concentrated at their center and additionally that $C(n, \mathcal{M}) \cap C(m, \mathcal{M}) = \emptyset$ for $|C(n, \mathcal{M})| > 2$ and $|C(m, \mathcal{M})| > 2$ with $\nu(n, \mathcal{M}) \neq \nu(m, \mathcal{M})$

such that

$C(n, \mathcal{M}) \diamond C(m, \mathcal{M})$

with a cover whose axes points are away from the center.
Proof. Let us suppose there exists at least a pair of CoPs of the form \( C(n, M) \) and \( C(m, M) \) with \( m \neq n \) such that \( C(n, M) \cap C(m, M) = \emptyset \) for \( |C(n, M)|, |C(m, M)| > 2 \) and additionally that
\[
\nu(n, M) \neq \nu(m, M)
\]
so that \( C(n, M) \circ C(m, M) \). It follows that there exists some CoP \( C(s, M) \) such that
\[
C(n, M) \cup C(m, M) \subseteq C(s, M)
\]
so that for each \([x] \in C(n, M) \cup C(m, M)\) there exists some \([y] \in C(n, M) \cup C(m, M)\) such that
\[
L_{[x],[y]} \in C(s, M).
\]
Under the conditions
\[
\nu(n, M) \neq \nu(m, M)
\]
and
\[
C(n, M) \cap C(m, M) = \emptyset
\]
it follows from the pigeon-hole principle and the uniqueness of the axes of CoPs there exists some \(L_{[x],[y]} \in C(s, M)\) such that \([x], [y] \in C(n, M)\) or \([x], [y] \in C(m, M)\). Without loss of generality let us assume that \([x], [y] \in C(n, M)\). By virtue of the embedding
\[
C(n, M) \subset C(s, M)
\]
the line \( L_{[x],[y]} \in C(n, M) \) is such that \( L_{[x],[y]} \neq L_{[u],[v]} \in C(n, M) \). It follows that the line \( L_{[x],[y]} \) must be a chord in \( C(n, M) \) and \( C(s, M) \) must be a child of the parent \( C(n, M) \). Now let us locate all the remaining chords \( L_{[u],[v]} \neq L_{[x],[y]} \) in the parent \( C(n, M) \). We claim that each chord \( L_{[u],[v]} \) must be an axis of the child \( C(s, M) \). Let us assume to the contrary that some chord \( L_{[u],[v]} \in C(n, M) \) is also a chord in the child \( C(s, M) \). Then there exist some axes
\[
L_{[u],[a]}, L_{[v],[b]} \in C(n, M).
\]
By virtue of the underlying embedding, it follows that the lines
\[
L_{[u],[a]}, L_{[v],[b]}
\]
cannot be axes of the CoP \( C(s, M) \) so that \( L_{[u],[a]} \) and \( L_{[v],[b]} \) are chords in \( C(s, M) \) with
\[
\Gamma([u],[b]) = \Gamma([v],[a]). \tag{10.1}
\]
It follows that at least one of \( L_{[u],[b]} \) and \( L_{[v],[a]} \) must be chords in \( C(s, M) \). Otherwise, it would mean both lines \( L_{[u],[b]} \in L_{[u],[b]} \in C(s, M) \) and \( L_{[v],[a]} = L_{[v],[a]} \in C(s, M) \), which in relation to \( (10.1) \) is absurd for axes points of CoPs. Without loss of generality let us assume \( L_{[u],[b]} \) is a chord then so is \( L_{[v],[a]} \) under the condition \( L_{[u],[a]}, L_{[v],[b]} \in C(n, M) \). Otherwise it would imply the chord \( L_{[u],[v]} \) must be an axis of \( C(s, M) \). Since all the axes points of \( C(n, M) \) are concentrated around the center, it certainly follows that
\[
\frac{n}{2} = \frac{a + u}{2} \approx a \quad \text{and} \quad \frac{n}{2} = \frac{a + u}{2} \approx u \tag{10.2}
\]
On the other hand is there exists no CoP $C$, because 3 and 7 are the only 3 primes which have a distance of 2 between each other.

Then we obtain \( \frac{n}{2} = \frac{b + v}{2} \approx b \) and \( \frac{n}{2} = \frac{b + v}{2} \approx v \) (10.3) so that we have \( a \approx b \approx u \approx v \) and we deduce that the co-axis point \([a], [v]\) of the cover CoP $C(s, M)$ is close to the center by the relation

\[
\frac{s}{2} = \frac{a + v}{2} \approx a \approx v
\]

which contradicts the requirement of the proximity of the axes points of the cover $C(s, M)$. It follows that $L_{[u], [v]}$ and $L_{[a], [b]}$ are also chords in $C(s, M)$ with

\[
\Gamma([u], [v]) = \Gamma([a], [b])
\]

since the lines $L_{[u], [a]}, L_{[v], [b]} \notin C(n, M)$ tied with the embedding $C(n, M) \subset C(s, M)$. It follows from (10.1) and (10.4)

\[
L_{[u], [a]}, L_{[v], [b]} \notin C(s, M)
\]

so that \( n = u + a = v + b = s \) and $C(n, M) = C(s, M)$, thereby contradicting the embedding

\[
C(n, M) \subset C(s, M).
\]

Thus each chord in $C(n, M)$ must be a axis of the child $C(s, M)$. The upshot is that the parent has only one child $C(s, M)$, which is impossible since $|C(n, M)| > 2$. $\square$

**Conjecture 10.4.** Let $C(n, M)$ and $C(m, M)$ be parents CoPs with the offspring $O_n$ and $O_m$, respectively. Then $C(n, M) \circ C(m, M)$ if and only if there exists some $C(s, M) \in O_n$ and $C(t, M) \in O_m$ such that

\[
C(s, M) \circ C(t, M).
\]

For a CoP there are two possibilities:

- The CoP admits embedding. Then holds Proposition 10.2 for the parents and for their children and Conjecture 10.3 is valid.
- The CoP do not admit embedding. An example for such CoPs is $C(n, \mathbb{P})$.

The following example demonstrates that Conjecture 10.3 not holds for such CoPs.

**Example 10.5.** We consider the weights of the CoPs

\[
\|C(16, \mathbb{P})\| = \{3, 5, 11, 13\}
\]
\[
\|C(18, \mathbb{P})\| = \{5, 7, 11, 13\}
\]
\[
\|C(24, \mathbb{P})\| = \{5, 7, 11, 13, 17, 19\}
\]
\[
\|C(12, \mathbb{P})\| = \{5, 7\}
\]

Then we obtain

\[
C(24, \mathbb{P}) \cup C(12, \mathbb{P}) = C(24, \mathbb{P})
\]
and therefore

\[
C(24, \mathbb{P}) \circ C(12, \mathbb{P}).
\]

On the other hand is

\[
\|C(16, \mathbb{P}) \cup C(18, \mathbb{P})\| = \{3, 5, 7, 11, 13\}.
\]

Because 3, 5, 7 are the only 3 primes which have a distance of 2 between each other there exists no CoP $C(n, \mathbb{P})$ for which holds that the last 3 weights have a distance.
of 2 between each other. Hence $C(16, \mathbb{P})$ and $C(18, \mathbb{P})$ are not compatible although they have children which are compatible.

We mind that we obtain a CoP from the union of $C(16, \mathbb{P})$ and $C(18, \mathbb{P})$ if we remove $[3]$ or $[7]$ from the union. In the first case we get $C(18, \mathbb{P})$ and in the second case $C(16, \mathbb{P})$. In both cases we have a so called weak compatibility $C(16, \mathbb{P}) \circ C(18, \mathbb{P})$.

**Definition 10.6.** Let $M \subseteq \mathbb{N}$ and $C(n, M)$ and $C(m, M)$ be any two CoPs. Then we say the CoPs $C(n, M)$ and $C(m, M)$ are weakly compatible if there exist some CoP $C(r, M)$ and a point $[z] \in C(n, M) \cup C(m, M)$ satisfying

$$C(n, M) \cup C(m, M) \setminus \{[z]\} \subseteq C(r, M).$$

such that for each $[x] \in C(n, M) \cup C(m, M)$ with $2x \neq n$ there exist some $[y] \in C(n, M) \cup C(m, M)$ so that

$$L_{[x],[y]} \in C(r, M).$$

We denote the weak compatibility by $C(n, M) \circ C(m, M)$. We call the CoP $C(r, M)$ also the cover of this compatibility.

Another example for weakly compatible CoPs are

\[
\|C(28, \mathbb{P})\| = \{5, 11, 17, 23\} \quad \text{and} \quad \|C(30, \mathbb{P})\| = \{7, 11, 13, 17, 19, 23\} \quad \text{and} \\
C(28, \mathbb{P}) \cup C(30, \mathbb{P}) \setminus \{[5]\} = C(30, \mathbb{P}) \\
\text{and therefore} \\
C(28, \mathbb{P}) \circ C(30, \mathbb{P}).
\]

Conjecture [10.4] could have several ramifications if it turns out to be true. Yet we believe it is very hard to establish as we found it far-fetched with the current tools developed thus far. Any progress on this conjecture would require an expansion on the notion of compatibility and their interplay with other concepts.

### 11. Extended Circles of Partition

In this section we introduce the notion of extended CoPs and demonstrate some important properties. Finally we give a partial proof of the binary Goldbach conjecture.

**Definition 11.1.** Let $M \subseteq \mathbb{N}$ and $C(n)$ be a CoP with $\mathbb{N}$ as base set. Then we denote

$$C^*(n, M) := \{[x] \in C(n) \mid \{x, n-x\} \cap \mathbb{M} \neq \emptyset, x > 2\}$$

as extended Circle of Partition. We abbreviate it as xCoP.

We denote by $O^n_\mathbb{M}(M)$ the extended family of the xCoP $C^*(n, M)$ as collection of all children $C^*(s, M)$ with principal axes $L_{[x],[y]} \in C^*(s, M)$, $s = x + y \neq n$ whereby $[x]$ or $[y]$ is not the center of the parent xCoP. We denote by $O^n_\mathbb{M}(M)$ the union of the parent xCoP with its extended family as complete extended family. With $F_n(M)$ we denote the set of the generators of a complete extended family.

We call an axis whose both axis points are members of $\mathbb{M}$ full–M axis and in the other case half–M axis. If $\mathbb{M} = \mathbb{P}$ then we say full–prime axis resp. half–prime axis.
While all axes of a CoP $C(n, \mathbb{M})$ are full-$\mathbb{M}$ axes the axes of an xCoP $C^*(n, \mathbb{M})$ are full-$\mathbb{M}$ or half-$\mathbb{M}$ axes.

**Proposition 11.2.** It holds $C(n, \mathbb{M}) \subseteq C^*(n, \mathbb{M})$ for all $n \in \mathbb{N}$ with $C(n, \mathbb{M}) \neq \emptyset$.

**Proof.** If holds $x \in \mathbb{M}$ and $n - x \notin \mathbb{M}$ then is $[x] \in C(n, \mathbb{M})$ as well as $[x] \in C^*(n, \mathbb{M})$. If is only $x \in \mathbb{M}$ and $n - x \notin \mathbb{M}$ or vice versa then is $[x] \in C^*(n, \mathbb{M})$ but $[x] \notin C(n, \mathbb{M})$. □

**Corollary 11.3.** Let $\mathbb{P}$ be the set of all prime numbers. Due to Proposition 11.2 holds for all $n \in 2\mathbb{N}$ with $C(n, \mathbb{P}) \neq \emptyset$

$$C(n, \mathbb{P}) \subseteq C^*(n, \mathbb{P}).$$

**Proposition 11.4.** Let $M_{a,d} \subset \mathbb{N}$ the set like in (11.3). Then is for all $n \in M_{2a,d}$

$$C(n, M_{a,d}) \equiv C^*(n, M_{a,d}).$$

**Proof.** Because of $n \in M_{2a,d}$ for each member $x$ of $M_{a,d}$ holds that also $n - x$ is a member of $M_{a,d}$. Therefore there exists no $x \in M_{a,d}$ with $n - x \notin M_{a,d}$ and vice versa. But these would be the extensions of $C(n, M_{a,d})$. □

Next we look at xCoPs with the set $\mathbb{P}$ of all prime numbers as base set.

**Proposition 11.5.** Let be $n \in 2\mathbb{N}, n \geq 8$. Then the xCoP $C^*(n, \mathbb{P})$ contains all odd primes not greater than $n - 3$ and it holds

$$|C^*(n, \mathbb{P})| \geq \pi(n - 3) - 1 \geq 2.$$

**Proof.** The xCoP $C^*(n, \mathbb{P})$ contains only odd numbers because if $x$ would be even $> 2$ then must also $n - x$ be even and therefore both are not prime. The first member of each such xCoP is $[3]$. Its axis partner is $[n - 3]$ and is a member of the xCoP because $3$ is prime. Therefore contains $C^*(n, \mathbb{P})$ prime numbers between 3 and not greater than $n - 3$. Not contained in $C^*(n, \mathbb{P})$ are all axis points $[x] \in C(n)$ and their axis partner $[n - u]$ which both are not prime. Because $|C(n)|$ contains all natural numbers $1 \leq x \leq n - 1$ then $|C(n)|$ contains also all primes $3 \leq p \leq n - 3$. And these will be not excluded by the condition $\{x, n - x\} \cap \mathbb{P} \neq \emptyset$. Therefore $C^*(n, \mathbb{P})$ contains all primes between 3 and less or equal $n - 3$ and hence it holds

$$|C^*(n, \mathbb{P})| \geq \pi(n - 3) - 1 \geq 2$$

because $\pi(8 - 3) - 1 = 2$. □

**Corollary 11.6.** From Proposition 11.5 follows that for all $n \in 2\mathbb{N}, n \geq 8$ holds

$$C^*(n, \mathbb{P}) \neq \emptyset$$

since the all contain the points $[3]$ and $[5]$ at least.

**Corollary 11.7.** From Proposition 11.3 follows that for all $n \in 2\mathbb{N}, n \geq 8$ with $C(n, \mathbb{P}) \neq \emptyset$ holds

$$C(n, \mathbb{P}) \cap C^*(n, \mathbb{P}) \neq \emptyset$$

because also $C(n, \mathbb{P})$ contains primes not greater than $n - 3$, but not all necessarily.
Additional we need the following lemmata.

**Lemma 11.8.** Let \( M \subseteq \mathbb{N} \) and \( C^*(n, M) \) an xCoP. Then the weights of the xCoP are symmetrically distributed around \( \frac{n}{2} \).

*Proof.* This is true because

\[
x_{i+1} - x_i = n - n + x_{i+1} - x_i = (n - x_i) - (n - x_{i+1}) \quad \text{for } i = 1, 2, \ldots, \left\lfloor \frac{k}{2} \right\rfloor
\]

if \( x_1, x_2, \ldots, x_k \) are the weights of the points of xCoP.

\( \square \)

**Corollary 11.9.** From Lemma 11.8 follows immediately that if \( \frac{n}{2} \) is a member of \( M \) then has \( C^*(n, M) \) an odd number of points. Else the number is even.

**Lemma 11.10.** Let \( M \subseteq \mathbb{N} \) and \( C^*(n, M) \) an xCoP. Then the generators of its children are symmetrically distributed around the generator of the parent xCoP.

*Proof.* Analogously to the proof of Proposition 8.5 we get for two arbitrary axes \( L_{[u],[v]}, L_{[x],[y]} \in C^*(n, M), u < x \) of the xCoP the following children generators

\[
s_1 = u + x < s_2 = u + y < n < t_2 = v + x < t_1 = v + y
\]

and the following distances

\[
s_2 - s_1 = u + y - u - x \quad \text{and} \quad t_1 - t_2 = v + y - v - x
\]

and hence

\[
s_2 - s_1 = y - x = t_1 - t_2.
\]

Because the chosen axes are arbitrary and always the parent generator is located in the middle of such inequalities the distances between the children generators are symmetrically distributed around \( n \).

\( \square \)

The statements of both lemmata are also true for unextended CoPs.

**Corollary 11.11.** From the proof of Lemma 11.10 concludes that the number of children of any xCoP is even and hence every complete extended family has an odd number of members.

**Theorem 11.12.** Let \( m, n \in 2\mathbb{N} \) and \( C^*(m, \mathbb{P}) \) and \( C^*(n, \mathbb{P}) \) be two xCoPs with \( m < n \) and \( m \geq 16 \). If holds \( C(k, \mathbb{P}) \neq \emptyset \) for \( k \in 2\mathbb{N} \mid 8 \leq k < n \) then \( F_n(\mathbb{P}) \) contains all even integers \( 8 \leq x \leq 2n - 8 \) and it holds

\[
F_m(\mathbb{P}) \subseteq F_n(\mathbb{P}).
\]

Additionally holds \( |F_n(\mathbb{P})| = n - 7 \). This means that \( C^*(n, \mathbb{P}) \) has \( n - 8 \) children.

*Proof.* Because the first three odd numbers \( \geq 3 \) all are primes the first three points which not lies on common axes or on a degenerated axis of all xCoPs are \([3], [5], [7]\) for \( m \geq 16 \). Ergo the first three generators of children of all such xCoPs are

\[
f_1 = 3 + 5 = 8, f_2 = 3 + 7 = 10 \quad \text{and} \quad f_3 = 5 + 7 = 12.
\]
Because of Lemma 11.10 we have only to prove that all even integers $8 \leq x < n$ are members of $F_n(P)$. Let $t$ be the cardinality of $F_n(P)$ and

$$s := \frac{t + 1}{2}.$$  

By virtue of Corollary 11.11 $t$ is an odd number and $F_n(P)$ has the parent generator $n$ in the middle and even children generators left and equal ones on the right side. Therefore $n$ is the $s^{th}$ element of $F_n(P)$

$$f_s = n.$$  

Since the second weight of all xCoPs is prime the point $[n - 5]$ is a member of $C^*(n, P)$ and $L[3][n-5]$ is not an axis and hence a principal axis for the child $C^*(n - 2, P)$. Hence the greatest member of $F_n(P)$ less than $n$ is

$$f_{s-1} = n - 2.$$  

Because of $C(k, P) \neq \emptyset$ for $k \in 2\mathbb{N} | 8 \leq k < n$ all such even numbers $k$ have at least one representation as sum of two primes. And by virtue of Proposition 11.5 the xCoP $C^*(n, P)$ contains all primes between 3 and not greater than $n - 3$. Therefore every even number between 8 and $n - 2$ has a representation as sum of two weights of $C^*(n, P)$ whose points don’t form an axis of $C^*(n, P)$. Therefore these even numbers are generators of children of the parent xCoP $C^*(n, P)$, hence the elements $f_1 = 8, f_2 = 10, \ldots, f_{s-1} = n - 2 \in F_n(P)$. This are

$$s - 1 = \frac{n - 2 - 8}{2} + 1 = \frac{n}{2} - 4$$

members. With it we can calculate

$$t = |F_n(P)| = 2s - 1 = n - 6 - 1 = n - 7.$$  

By virtue of Lemma 11.10 the members from $f_{s+1}$ until $f_t$ are the $s - 1$ even numbers $> n$. The greatest children generator is

$$f_t = n - 3 + n - 5 = 2n - 8.$$  

Therefore all even numbers between 8 and $2n - 8$ are the members of $F_n(P)$ and it holds $F_m(P) \subseteq F_n(P)$ because of $|F_m(P)| < |F_n(P)|$.

Between 8 and $2n - 8$ there are exactly $n - 7$ numbers. Hence $C^*(n, P)$ has $n - 8$ children. Out of the even numbers between 8 and $2n - 8$ there cannot be a child generator. 

It is easy to check that the xCoPs $C^*(2, P)$ until $C^*(10, P)$ have no children.

**Corollary 11.13.** Because of $F_m(P) \subseteq F_n(P)$ by $m < n$ all xCoPs $C^*(n, P)$ with $n \geq 12$ and $C(k, P) \neq \emptyset | 8 \leq k < n$ holds

$$\hat{O}_m^* \subseteq \hat{O}_n^*$$

if $m < n$, which means that all such two xCoPs are isomorphic with a high degree (see Definition 9.7).

**Corollary 11.14.** Due to [3] is a point of all xCoPs $C^*(n, P)$ for $n \geq 6$ all the xCoPs are connected (see Proposition 7.2).
Theorem 11.15. Let $n \in 2\mathbb{N}$, $C^*(n, \mathbb{P})$ be a $xCoP$ with $n \geq 8$ and $C(n, \mathbb{P}) \neq \emptyset$. Then exists an axis $L_{[x],[n-x]} \in C^*(n, \mathbb{P})$ such that $L_{[x],[n-x]}$ is also an axis of $C(n, \mathbb{P})$.

Proof. By virtue of Corollary 11.17 there exists a point $[x]$ which is member of $C^*(n, \mathbb{P})$ as well as of $C(n, \mathbb{P})$. Because $C(n, \mathbb{P})$ contains only points with prime weights $x$ must be prime and also $[n-x]$ is member of $C(n, \mathbb{P})$ and has a prime weight. But also $[n-x]$ must be a member of $C^*(n, \mathbb{P})$ because $x$ is prime and $x + (n-x) = n$. Hence we have an axis $L_{[x],[n-x]}$ which belongs to $C(n, \mathbb{P})$ as well as to $C^*(n, \mathbb{P})$.

Definition 11.16. Let $C^*(n, \mathbb{M})$ be a nonempty $xCoP$. We denote by

$$\nu^*(n, \mathbb{M}) := \# \{L_{[x]}, [y] \in C^*(n, \mathbb{M})\}$$

the number of real axes in the $xCoP$ $C^*(n, \mathbb{M})$.

Corollary 11.17. Let $\mathbb{M} \subset \mathbb{N}$ and $C^*(n, \mathbb{M})$ be a nonempty $xCoP$. Then holds

$$\nu^*(n, \mathbb{M}) = \# \{L_{[x]}, [y] \in C^*(n, \mathbb{M})\}$$

$$= \# \{L_{[x]}, [y] \in C(n) \mid \{x, y\} \cap \mathbb{M} \neq \emptyset\}$$

$$= \nu(n, \mathbb{M}) + \# \{L_{[x]}, [y] \in C(n) \mid x \in \mathbb{M}, y \notin \mathbb{M}\}$$

$$= \nu(n, \mathbb{M}) + \tilde{\nu}(n, \mathbb{M})$$

with $\tilde{\nu}(n, \mathbb{M}) := \# \{L_{[x]}, [y] \in C(n) \mid x \in \mathbb{M}, y \notin \mathbb{M}\}$ as the number of half-$\mathbb{M}$ axes of the $xCoP$ $C^*(n, \mathbb{M})$ and $\nu(n, \mathbb{M})$ like defined in Definition 12.3 the number of full-$\mathbb{M}$ axes.

Theorem 11.18. For the density of points by virtue of Definition 6.2 with $\mathbb{M} = \mathbb{N}$ and $\mathbb{H} = \mathbb{P}$ holds

$$\mathcal{D}(\mathbb{P}_{C(\infty)}) \sim \frac{1}{\log n}.$$

Proof. By virtue of Definition 6.2 and Corollary 11.17 holds with $\mathbb{M} = \mathbb{N}$ and $\mathbb{H} = \mathbb{P}$

$$\mathcal{D}(\mathbb{P}_{C(\infty)}) \sim \frac{\# \{L_{[x],[n-x]} \in C(n) \mid \{x, n-x\} \cap \mathbb{P} \neq \emptyset\}}{\nu(n, \mathbb{N})}$$

$$\sim \frac{\# \{L_{[x],[n-x]} \in C^*(n)\}}{\nu(n, \mathbb{N})}$$

$$\sim \frac{\nu^*(n, \mathbb{P})}{\nu(n, \mathbb{N})}$$

$$= \frac{\pi(n-3)-1}{n-1} \sim \frac{1}{\log n}.$$

Theorem 11.19 (Binary Goldbach Conjecture). For all $n \in 2\mathbb{N}, n \geq 6$ there exists at least one representation as sum of two primes.

Proof. First we note that the following statement is an analogon to the claim:
There is no \( x\text{CoP} \ C^*(n, \mathbb{P}) \) for \( n \in 2\mathbb{N}, n \geq 6 \) with only half–prime axes, because in this case there is no empty CoP for \( n \in 2\mathbb{N}, n \geq 6 \) and hence for each such \( n \) there exists at least one representation as sum of two primes (weights of axis points).

By virtue of Proposition 11.5 the weights of an \( x\text{CoP} \) contains all primes between 3 and not greater than \( n - 3 \). Let us assume contrarily that \( C^*(n_o, \mathbb{P}) \) is an \( x\text{CoP} \) with only half–prime axes and \( n_o \) is the least generator of such \( x\text{CoPs} \). This means that holds

\[
C(k, \mathbb{P}) \neq \emptyset \text{ for } 6 \leq k \leq n_o - 2.
\]

Because in virtue of our assumtion the weights of the last three points \([n_o - 3], [n_o - 5] \) and \([n_o - 7] \) cannot be prime we find in this case in \(||C^*(n_o, \mathbb{P})||\) only the primes between 3 and not greater than \( n_o - 9 \).

And because of \( \text{11.1} \) there is always an \([x] \in C^*(n_o, \mathbb{P})\) with \( x \in \mathbb{P} \) and an \( r \in 2\mathbb{N} | 2 \leq r \leq x - 3 \) such that \([x - r] \in C(n_o - r, \mathbb{P}) \). Then also holds

\[
L_{[x-r],[n_o-r-(x-r)]} = L_{[x-r],[n_o-x]} \in C(n_o - r, \mathbb{P}).
\]

And because of Theorem 2.20 holds for the point \([n_o - x] \in C^*(n_o, \mathbb{P})\), the axis partner of \([x] \), that \( n_o - x \) is prime. But this contradicts the premise that all axes are half-prime axes since also \( x \) is prime.

\[\square\]

This proof must be completed in order to remove “...”.

12. The Asymptotic Binary Goldbach and Lemoine Conjectures

The Goldbach conjecture was born in 1742 through a correspondence between the German mathematician Christian Goldbach and the Swiss mathematician Leonard Euler. There are two known versions of the problem: the binary case and the ternary situation. The binary version ask whether every even number greater than 6 can be represented as the sum of two primes, whereas the ternary version ask whether every odd number greater than 7 can be expressed as the sum of three primes. The ternary version, however, was very recently solved in the preprint [14] that compiled and build on several chain of works. Although the binary problem has not been solved yet, significant strides have been made on its variations. The first significant step in this direction can be found in (see [10]), which demonstrates that every even number can be expressed as the sum of at most \( C \) primes, where \( C \) is a practically computable constant. In the early twentieth century, G.H Hardy and J.E Littlewood assuming the Generalized Riemann hypothesis (see [7]), showed that the number of even numbers \( \leq X \) and violating the binary Goldbach conjecture is much less than \( X^{\frac{1}{2}+c} \), where \( c \) is a small positive constant. Using sieve theory techniques, Jing-run Chen [12] showed that every even number can either be written as a sum of two prime numbers or a prime number and a number which is a product of two primes. It is well known that almost all even numbers can be expressed as the sum of two prime numbers, with the density of even numbers representable in this fashion being one [9], [8]. It is also known that there exists a constant \( K \) such that any even number can be expressed as the sum of two prime numbers and a maximum of \( K \) powers of two, where \( K = 13 \) [13].
Lemoine’s conjecture, on the other hand, is the assertion that every odd number greater than 5 can be written as the sum of a prime number and a double of a prime number. More formally, the conjecture states

**Conjecture 12.1.** The equation

\[ 2n + 1 = p + 2q \]

always has a solution in the primes (not necessarily distinct) for all \( n > 2 \).

The conjecture was first posed by Émile Lemoine \[6\] in 1895 but was wrongly attributed to Hyman Levy \[11\], who had thought very deeply about it; hence, the name Lemoine or sometimes Levy conjecture. The conjecture is on par with other additive prime number problems like the binary Goldbach conjecture (see \[8\],\[9\],\[12\]) and the ternary Goldbach conjecture (see \[14\]). It is easy to see that the Lemoine conjecture is much stronger than and implies the ternary Goldbach conjecture.

We devised a method that we believe could be a useful tool and a recipe for analyzing issues pertaining to the partition of numbers in designated subsets of \( \mathbb{N} \) in our work \[15\], which was partially inspired by the binary Goldbach conjecture and its variants. The technique is fairly simple, and it is similar to how the points on a geometric circle can be arranged.

In an effort to make our work more self-explanatory, we have chosen to provide a little background of the method of circles of partition from \[15\] in the following sequel.

**Definition 12.2.** Let \( n \in \mathbb{N} \) and \( M \subseteq \mathbb{N} \). We denote with \( C(n, M) = \{ [x] \mid x, n - x \in M \} \) the Circle of Partition generated by \( n \) with respect to the subset \( M \). We will abbreviate this in the further text as CoP. We call members of \( C(n, M) \) as points and denote them by \( [x] \). For the special case \( M = \mathbb{N} \) we denote the CoP shortly as \( C(n) \). We denote with \( \| [x] \| := x \) the weight of the point \( [x] \) and correspondingly the weight set of points in the CoP \( C(n, M) \) as \( \|C(n, M)\| \). Obviously holds \( \|C(n)\| = \{1, 2, \ldots, n - 1\} \).

**Definition 12.3.** We denote the line \( L_{[x],[y]} \) joining the point \( [x] \) and \( [y] \) as an axis of the CoP \( C(n, M) \) if and only if \( x + y = n \). We say the axis point \( [y] \) is an axis partner of the axis point \( [x] \) and vice versa. We do not distinguish between \( L_{[x],[y]} \) and \( L_{[y],[x]} \), since it is essentially the same axis. The point \( [x] \in C(n, M) \) such that \( 2x = n \) is the center of the CoP. If it exists then we call it as a degenerated axis \( L_{[x]} \) in comparison to the real axes \( L_{[x],[y]} \). We denote the assignment of an axis \( L_{[x],[y]} \) to a CoP \( C(n, M) \) as

\[ L_{[x],[y]} \hat{\in} C(n, M), \]

which means \( [x], [y] \in C(n, M) \) with \( x + y = n \).

Important properties of CoPs are

- Each axis is uniquely determined by points \( [x] \in C(n, M) \).
- Each point of a CoP \( C(n, M) \) except its center has exactly one axis partner.
We denote the assignment of an axis $L_{[x],[y]}$ resp. $L_{[x]}$ to a CoP $C(n,M)$ as
$L_{[x],[y]} \in C(n,M)$, which means $[x],[y] \in C(n,M)$ and $x + y = n$ resp.
$L_{[x]} \in C(n,M)$, which means $[x] \in C(n,M)$ and $2x = n$
and the number of real axes of a CoP as
$$\nu(n,M) := \# \{ L_{[x],[y]} \in C(n,M) \mid x < y \}. \quad \text{(12.1)}$$
Obviously holds
$$\nu(n,M) = \left\lfloor \frac{k}{2} \right\rfloor, \text{ if } |C(n,M)| = k.$$

12.1. The Squeeze Principle. In this section we introduce the squeeze principle and its consequences if the set of all odd prime numbers is the base set of CoPs.

Theorem 12.4 (The squeeze principle). Let $B \subset M \subset N$ and $C(m,B)$ and $C(m+t,B) \neq \emptyset$ for $t \geq 4$. If there exists $L_{[x],[y]} \in C(m+t,M)$ with $x \in B$ and $x < y$ such that
$$y > w = \max \{ u \in |C(m,M)| \mid u \in B \} > m - x, \quad \text{(12.2)}$$
then there exists $C(s,B) \neq \emptyset$ such that $m < s < m + t$.

Proof. In virtue of (12.2) holds $w \in B$. As required the axis $L_{[x],[y]} \in C(m+t,M)$ exists with $x \in B$ such that $m - w < x < y$. Then we have the inequality
$$m = w + (m - w) < \underline{x} + w = w + (m + t - y) = m + t + (w - y)$$
$$< m + t, \text{ since } y > w \quad \text{(12.3)}$$
and $m - w < x = m + t - y$ holds $y - w < t$. With $s = w + x$ there is an axis $L_{[x],[w]} \in C(s,B)$ and it follows that $C(s,B) \neq \emptyset$ with $m < s < m + t$. \hfill \Box

Theorem 12.4 can be viewed as a basic tool-box for studying the possibility of partitioning numbers of a particular parity with components belonging to a special subset of the integers. It works by choosing two non-empty CoPs with the same base set and finding further non-empty CoPs with generators trapped in between these two generators. This principle can be used in an ingenious manner to study the broader question concerning the feasibility of partitioning numbers with each summand belonging to the same subset of the positive integers. We launch the following proposition as an outgrowth of Theorem 12.4.

Proposition 12.5 (The interval binary Goldbach partition detector). Let $P$ be the set of all prime numbers and $C(m,P),C(m+t,P) \neq \emptyset$ by $t \geq 4$. If there exists $L_{[x],[y]} \in C(m+t,N)$ with $x \in P$ and $x < y$ such that
$$y > w = \max \{ u \in |C(m,N)| \mid u \in P \} > m - x \quad \text{(12.4)}$$
then there must exists $m < s < m + t$ such that $C(s,P) \neq \emptyset$.

Proof. This is a consequence of Theorem 12.4 by taking $M = N$ and $B = P$. \hfill \Box

Proposition 12.6 (Interval Goldbach partition). Let $P$ be the set of all prime numbers and $C(m,P),C(m+t,P) \neq \emptyset$ for $t \geq 4$. If $m - 1 \in P$ then there exist some $s \equiv 0(\text{mod } 2)$ with $m < s < m + t$ such that $C(s,P) \neq \emptyset$. 

Proof. Under the requirements \( C(m, \mathbb{P}), C(m + t, \mathbb{P}) \neq \emptyset \) for \( t \geq 4 \) and with \( w \) in virtue of (12.4), we choose \( L_{[3],[p]} \in C(m + t, \mathbb{N}) \) so that \( w = m - 1 \) and \( y > w \) since \( y = m + t - 3 > m \) for \( t \geq 4 \) and \( m - 1 \in \mathbb{P} \). The inequality holds

\[
y - w = y - (m - 1) \leq (m + t - 3) - (m - 1) < t
\]

and the conditions in Proposition 12.5 are satisfied, so that there exists some \( s \equiv 0 \text{(mod 2)} \) with \( m < s < m + t \) such that \( C(s, \mathbb{P}) \neq \emptyset \), f.i. \( s = 3 + m - 1 = m + 2 \) with \( L_{[3],[m-1]} \in C(m + 2, \mathbb{P}) \).

Proposition 12.7. Let \( \mathbb{P} \) be the set of all prime numbers and \( C(m, \mathbb{P}), C(m + t, \mathbb{P}) \neq \emptyset \) for \( t \geq 4 \) such that \( m - 1 \in \mathbb{P} \). Then there are finitely many \( s \equiv 0 \text{(mod 2)} \) with \( m < s < m + t \) such that \( C(s, \mathbb{P}) \neq \emptyset \).

Proof. The result is obtained by iterating repeatedly on the generators \( s \equiv 0 \) (mod 2) with \( m < s < m + t \) such that \( C(s, \mathbb{P}) \neq \emptyset \).

Theorem 12.8 (Conditional Goldbach). Let \( \mathbb{P} \) be the set of all prime numbers and \( m \in 2\mathbb{N} \) such that \( C(m, \mathbb{P}) \neq \emptyset \) for \( m \) sufficiently large. If for all \( t \geq 4 \) there exists \( L_{[x],[y]} \in C(m + t, \mathbb{N}) \) with \( x \in \mathbb{P} \) and \( y > w \) such that

\[
y > w = \max\{u \in ||C(m, \mathbb{N})|| \mid u \in \mathbb{P}\} > m - x,
\]

then there are CoPs \( C(s, \mathbb{P}) \neq \emptyset \) for all (sufficiently large) \( s \in 2\mathbb{N} \mid s > m \).

Proof. It is known that there are infinitely many even numbers that can be written as the sum of two primes, so that for \( m \in 2\mathbb{N} \) sufficiently large with \( C(m, \mathbb{P}) \neq \emptyset \) then \( t \geq 4 \) can be chosen arbitrarily large so that \( C(m + t, \mathbb{P}) \neq \emptyset \). Under the requirements and appealing to Proposition 12.5 there must exist some \( s \equiv 0 \) (mod 2) with \( m < s < m + t \) such that \( C(s, \mathbb{P}) \neq \emptyset \). Now we continue our arguments on the intervals of generators \([m, s]\) and \([s, s + r]\). If there exist some \( u, v \in 2\mathbb{N} \) such that \( m < u < s \) and \( s < v < s + r \), then we repeat the argument under the requirements (for arbitrary \( t \)) to deduce that \( C(u, \mathbb{P}) \neq \emptyset \) and \( C(v, \mathbb{P}) \neq \emptyset \). We can iterate the process repeatedly so long as there exists some even generators trapped in the following sub-intervals of generators \([m, u], [u, s], [s, v], [v, v + r]\) where \( v + r = m + t \) for \( t \geq 4 \). Since \( t \) can be chosen arbitrarily so that \( C(m + t, \mathbb{P}) \neq \emptyset \), the assertion follows immediately.

Now we use the squeeze principle to solve the Lemoine conjecture in analogy to its using for the binary Goldbach conjecture above.

Proposition 12.9 (The first interval Lemoine partition detector). Let \( \mathbb{P} \) and \( 2\mathbb{P} \) be the set of all prime numbers and their doubles, respectively, and \( C(m, \mathbb{P} \cup 2\mathbb{P}), C(m + t, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \) by \( t \geq 4 \). If there exists \( L_{[x],[y]} \in C(m + t, \mathbb{N}) \) with \( x \in \mathbb{P} \) and \( y > w \) such that

\[
y > w = \max\{u \in ||C(m, \mathbb{N})|| \mid u \in \mathbb{P} \cup 2\mathbb{P}\} \in 2\mathbb{P} > m - x \tag{12.5}
\]

then there must exist \( m < s < m + t \) such that \( C(s, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \).

Proof. This is a consequence of Theorem 12.3 by taking \( M = \mathbb{N} \) and \( B = \mathbb{P} \cup 2\mathbb{P} \).
Lemma 12.12. Elementary results which will feature prominently in our arguments.

Proof. From 1938 (see [8]) that the binary Goldbach conjecture is true for almost all prime numbers and their doubles, respectively, and $C(m, \mathbb{P} \cup 2\mathbb{P}), C(m + t, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$ for $t \geq 4$. If there exists $L_{[x], [y]} \in C(m + t, \mathbb{N})$ with $x \in 2\mathbb{P}$ and $x < y$ such that

$$y > w = \max \{ u \in |C(m, \mathbb{N})| \mid u \in \mathbb{P} \cup 2\mathbb{P} \} \in \mathbb{P} > m - x \quad (12.6)$$

then there must exist $m < s < m + t$ such that $C(s, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$.

Proof. The proof is the same as in Proposition 12.5.

Theorem 12.11. Conditional Lemoine. Let $\mathbb{P}$ and $2\mathbb{P}$ be the set of all prime numbers and their doubles, respectively, and $m \in 2\mathbb{N} + 1$ such that $C(m, \mathbb{P}) \neq \emptyset$ for $m$ sufficiently large. If for all $t \geq 4$ there exists $L_{[x], [y]} \in C(m + t, \mathbb{N})$ with $x \in \mathbb{P}$ and $x < y$ such that

$$y > w = \max \{ u \in |C(m, \mathbb{N})| \mid u \in \mathbb{P} \cup 2\mathbb{P} \} \in \mathbb{P} > m - x,$$

or there exists $L_{[x], [y]} \in C(m + t, \mathbb{N})$ with $x \in 2\mathbb{P}$ and $x < y$ such that

$$y > w = \max \{ u \in |C(m, \mathbb{N})| \mid u \in \mathbb{P} \cup 2\mathbb{P} \} \in \mathbb{P} > m - x$$

then there are CoPs $C(s, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$ for all (sufficiently large) $s \in 2\mathbb{N} + 1 \mid s > m$.

Proof. It is known that there are infinitely many odd numbers that can be written as the sum of a prime and a double of a prime, so that for $m \in 2\mathbb{N} + 1$ sufficiently large with $C(m, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$ then $t \geq 4$ can be chosen arbitrarily large such that $C(m + t, \mathbb{P}) \neq \emptyset$. Under the requirements and appealing to Proposition 12.5 and Proposition 12.10 there must exist some $s \equiv 1 \mod 2$ with $m < s < m + t$ such that $C(s, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$. Now we continue our arguments on the intervals of generators $[m, s]$ and $[s, s + r]$. If there exist some $u, v \in 2\mathbb{N} + 1$ such that $m < u < s$ and $s < v < s + r$, then we repeat the argument under the requirements (for arbitrary $t$) to deduce that $C(u, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$ and $C(v, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$. We can iterate the process repeatedly so long as there exists some odd generators trapped in the following sub-intervals of generators $[m, u], [u, s], [s, v], [v, v + r]$ where $v + r = m + t$ for $t \geq 4$. Since $t$ can be chosen arbitrarily so that $C(m + t, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$, the assertion follows immediately.

12.2. Application to the Binary Goldbach Conjecture. In this section we apply the notion of the quotient complex circles of partition and the squeeze principle to study the binary Goldbach conjecture in the very large. Despite Estermann’s proof from 1938 (see [8]) that the binary Goldbach conjecture is true for almost all positive integers, we can use our tool to establish and prove independently the binary Goldbach conjecture in an asymptotic sense. We lay down the following elementary results which will feature prominently in our arguments.

Lemma 12.12. (The prime number theorem). Let $\pi(m)$ denote the number of prime numbers less than or equal to $m$ and $p_{\pi(m)}$ denotes the $\pi(m)$th prime number. Then we have the asymptotic relation

$$p_{\pi(m)} \sim m \left(1 - \frac{\log \log m}{\log m}\right).$$
Proof. This is an easy consequence by combining the two versions of the prime number theorem
\[ \pi(m) \sim \frac{m}{\log m} \quad \text{and} \quad p_k \sim k \log k \]
where \( p_k \) denotes the \( k \)th prime number. Since with \( k = \pi(m) \) we get
\[ p_k = p_{\pi(m)} \sim \frac{m}{\log m} \log \left( \frac{m}{\log m} \right) \]
\[ = \frac{m}{\log m} (\log m - \log \log m) \]
\[ = m \left( 1 - \frac{\log \log m}{\log m} \right). \]

Obviously holds with the variable denotations from the previous section
\[ w = \max\{ u \in ||C(m, N)|| \mid u \in \mathbb{P} \} = p_{\pi(m)}. \quad (12.7) \]

Lemma 12.13 (Bertrand’s postulate). There exists a prime number in the interval \((k, 2k)\) for all \( k > 1 \).

The formula in Lemma 12.12 obviously suggests that the \( \pi(m)^{th} \) prime number satisfies and implies the asymptotic relation \( p_{\pi(m)} \sim m \). While this is valid in practice, it does not actually help in measuring the asymptotic of the discrepancy between the maximum prime number less than \( m \) and \( m \). It gives the misleading impression that this discrepancy has absolute difference tending to zero in the very large. We reconcile this potentially nudging flaw by doing things slightly differently.

Lemma 12.14 (The little lemma). Let \( \mathbb{P} \) be the set of all prime numbers and \( m \in \mathbb{N} \) be sufficiently large such that \( C(m, \mathbb{P}) \neq \emptyset \). Then for all \( x \in \mathbb{P} \) satisfying \( \frac{m \log \log m}{\log m} < x < \frac{m \log(m \log m)}{\log m} \) the asymptotic relation and inequalities
\[ m - w \sim \frac{m \log \log m}{\log m} \]
and
\[ 0 \lesssim |w - (m + t - x)| \lesssim t \]
hold for \( t \geq 4 \).

Proof. Appealing to the prime number theorem, we obtain with (12.7) the asymptotic inequalities
\[ m - w = m - p_{\pi(m)} \]
\[ \sim m - m \left( 1 - \frac{\log \log m}{\log m} \right) \]
\[ = \frac{m \log \log m}{\log m} \]
for all sufficiently large \( m \in 2\mathbb{N} \) and
\[
m + t - x > m + t - \frac{m \log(\log m)^2}{\log m} = m(1 - \frac{\log(\log m)^2}{\log m}) + t \\
\sim m + t > p_{\pi(m)} = w
\]
and
\[
|w - (m + t - x)| = |m + t - x - p_{\pi(m)}| < |m + t - \frac{m \log \log m}{\log m} - p_{\pi(m)}| \\
\sim |m + t - \frac{m \log \log m}{\log m} - m(1 - \frac{\log \log m}{\log m})| = t
\]
for \( t \geq 4 \).

We are now ready to prove the binary Goldbach conjecture for all sufficiently large even numbers. The following result is a culmination and to a larger extent a mishmash of ideas espoused in this paper.

**Theorem 12.15 (Asymptotic Goldbach theorem).** Every sufficiently large even number can be written as the sum of two prime numbers.

**Proof.** The claim is equivalent to the statement:

For every sufficiently large even number \( n \) holds \( C(n, \mathbb{P}) \neq \emptyset \).

It is known that there are infinitely many even numbers \( m > 0 \) with \( C(m, \mathbb{P}) \neq \emptyset \). Let us choose \( m \in 2\mathbb{N} \) sufficiently large such that \( C(m, \mathbb{P}) \neq \emptyset \) and choose \( t \geq 4 \) such that \( C(m + t, \mathbb{P}) \neq \emptyset \). Let us choose a prime number \( x < m \log \log m \log m \) such that \( x > m - \frac{m \log \log m}{\log m} \), since by Bertrand’s postulate (Lemma 12.13) there exists a prime number \( x \) such that \( x \in (k, 2k) \) for every \( k > 1 \). Then we get for the axis partner \( |y| \) of the axis point \( |x| \) of \( L_{[x], [y]} \in C(m + t, \mathbb{N}) \) the inequality
\[
y = m + t - x > m + t - \frac{m \log(\log m)^2}{\log m} = m(1 - \frac{\log(\log m)^2}{\log m}) + t \\
\sim m + t > p_{\pi(m)} = w
\]
for \( t \geq 4 \) and by appealing to Lemma 12.14 also the following asymptotic inequalities
\[
m - w \sim \frac{m \log \log m}{\log m} < x
\]
and
\[
|y - w| = |(m + t - x) - w| = |m - w + t - x| \leq |x + t - x| = t.
\]
Then the requirements in Theorem 12.8 are fulfilled asymptotically with

\[ y \gtrapprox w \quad \text{and} \quad x \gtrapprox m - w \quad \text{and} \quad 0 \lesssim |y - w| \lesssim t \]

and the result follows by arbitrarily choosing \( t \geq 4 \) so that \( C(m + t, \mathbb{P}) \neq \emptyset \) and adapting the proof in Theorem 12.8. \( \square \)

12.3. Application to the Lemoine Conjecture. In this section we apply the notion of the quotient complex circles of partition and the squeeze principle to study Lemoine’s conjecture in the very large. We begin with the following preparatory elementary results.

**Lemma 12.16.** Let \( \pi(m) \) denotes the number of prime numbers less than or equal to \( m \) and \( p_{\pi(m)} \) denotes the \( \pi(m) \)th prime number. Then we have the asymptotic relations

\[
p_{\pi(m)} \sim m \left( 1 - \frac{\log \log m}{\log m} \right) \sim 2p_{\pi(m/2)}.
\]

**Proof.** The left asymptotic relation is proved in Lemma 12.12. Now we replace in its result \( m \) by \( m/2 \) and get

\[
2p_{\pi(m/2)} \sim 2^{m/2} \left( 1 - \frac{\log \log m}{\log m} \right) \\
= m \left( 1 - \frac{\log(\log m - \log 2)}{\log(\log m - \log 2)} \right) \\
\sim m \left( 1 - \frac{\log \log m}{\log m} \right).
\]

Obviously holds with the variable denotations from the previous section

\[ w = \max\{u \in ||C(m, \mathbb{N})|| \mid u \in \mathbb{P} \cup 2\mathbb{P}\} = p_{\pi(m)} \quad (12.8) \]

provides \( w \in \mathbb{P} \) and

\[ w' = \max\{u \in ||C(m, \mathbb{N})|| \mid u \in \mathbb{P} \cup 2\mathbb{P}\} = 2p_{\pi(m/2)} \quad (12.9) \]

provides \( w' \in 2\mathbb{P} \).

**Lemma 12.17 (The first little lemma).** Let \( \mathbb{P} \) and \( 2\mathbb{P} \) be the set of all prime numbers and their doubles, respectively, and \( m \in \mathbb{N} \) be sufficiently large such that \( C(m, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \). Then for all \( x' \in 2\mathbb{P} \) with \( x' = 2x \) for \( x \in \mathbb{P} \) satisfying

\[
\frac{m \log \log m}{2 \log m} < x < \frac{m \log \log m}{\log m}
\]

the asymptotic relation and inequalities

\[
m - w \sim \frac{m \log \log m}{\log m}
\]

and

\[
0 \lesssim |w - (m + t - x')| \lesssim t
\]

hold for \( t \geq 4 \).
Proof. Due to Lemma 12.13 there is a prime between \( m \log \log m \) and \( \frac{m \log \log m}{2 \log m} \).

Appealing to the prime number theorem, we obtain with (12.8) the asymptotic inequalities

\[
m - w = m - p_{\pi(m)} \\
\sim m - m \left( 1 - \frac{\log \log m}{\log m} \right) \\
= \frac{m \log \log m}{\log m}
\]

for all sufficiently large \( m \in 2\mathbb{N} + 1 \) and

\[
m + t - x' = m + t - 2x > m + t - \frac{2m \log \log m}{\log m} \\
= m \left( 1 - \frac{\log \log m}{\log m} \right) + t \\
\sim m + t \geq p_{\pi(m)} = w
\]

and

\[
|w - (m + t - x')| = |m + t - x' - p_{\pi(m)}| \\
< |m + t - \frac{m \log \log m}{\log m} - p_{\pi(m)}| \\
\sim \left| m + t - \frac{m \log \log m}{\log m} - m \left( 1 - \frac{\log \log m}{\log m} \right) \right| \\
= t
\]

for \( t \geq 4 \). \( \square \)

**Lemma 12.18** (The second little lemma). Let \( \mathbb{P} \) be the set of all prime numbers and their doubles, respectively, and \( m \in \mathbb{N} \) be sufficiently large such that \( C(m, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \). Then for all \( x \in \mathbb{P} \) satisfying

\[
\frac{m \log \log m}{\log m} < x < \frac{m \log \log m}{2 \log m}
\]

the asymptotic relation and inequalities

\[
m - w' \sim \frac{m \log \log m}{\log m}
\]

and

\[
0 \lesssim |w' - (m + t - x)| \lesssim t
\]

hold for \( t \geq 4 \).
Proof. Due to Lemma 12.13 there is a prime between \( \frac{m \log \log m}{\log m} \) and \( \frac{m \log(m \log m)^2}{\log m} \). Appealing to the prime number theorem, we obtain with (12.9) the asymptotic inequalities
\[
m - w' = m - 2p_{\pi(m)}^\frac{1}{2} \sim m - m \left(1 - \frac{\log \log m}{\log m}\right) = m \frac{\log \log m}{\log m}
\]
for all sufficiently large \( m \in 2\mathbb{N} + 1 \) and
\[
m + t - x > m + t - \frac{m \log(m \log m)^2}{\log m} = m \left(1 - \frac{\log(m \log m)^2}{\log m}\right) + t \sim m + t \geq p_{\pi(m)} \sim 2p_{\pi(m)} = w'
\]
and
\[
|w' - (m + t - x)| = |m + t - x - 2p_{\pi(m)}^\frac{1}{2}| < |m + t - \frac{m \log \log m}{\log m} - 2p_{\pi(m)}^\frac{1}{2}| \sim \left|m + t - \frac{m \log \log m}{\log m} - m \left(1 - \frac{\log \log m}{\log m}\right)\right| = t
\]
for \( t \geq 4 \). \hfill \square

We are now ready to prove the Lemoine conjecture for all sufficiently large odd numbers. It is a case-by-case argument and a culmination of ideas espoused in this paper.

**Theorem 12.19 (Asymptotic Lemoine theorem).** Every sufficiently large odd number can be written as a sum of a prime number and a double of a prime number.

**Proof.** The claim is equivalent to the statement:

For every sufficiently large odd number \( n \in 2\mathbb{N} + 1 \) holds \( C(n, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \) since only the sum of an odd and an even number provides an odd number and therefore each axis \( \mathbb{L}_{[x],[y]} \in C(m, \mathbb{P} \cup 2\mathbb{P}) \) has an odd and an even axis point.

It is known that there are infinitely many odd numbers \( m > 0 \) with \( C(m, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \). Let us choose \( m \in 2\mathbb{N} + 1 \) sufficiently large such that \( C(m, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \) and choose \( t \geq 4 \) such that \( C(m + t, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset \). Now, we distinguish and examine two special cases as below:

- The case
  \[
w = \max\{u \in ||C(m, \mathbb{N})|| \mid u \in \mathbb{P} \cup 2\mathbb{P}\} = p_{\pi(m)}
\]
- The case
  \[
w' = \max\{u \in ||C(m, \mathbb{N})|| \mid u \in \mathbb{P} \cup 2\mathbb{P}\} = 2p_{\pi(m)}^\frac{1}{2}
\]
In the case
\[ w = \max\{ u \in ||C(m, N)|| \mid u \in \mathbb{P} \cup 2\mathbb{P} \} = p_{\pi(m)} \]
then we choose a prime number \( x < \frac{m \log \log m}{\log m} \) such that \( x > \frac{m \log \log m}{2 \log m} \), since by Bertrand’s postulate (Lemma 12.13) there exists a prime number \( x \) such that \( x \in (k, 2k) \) for every \( k > 1 \) and set \( 2x = x' \in 2\mathbb{P} \). Then we get for the axis partner \([y]\) of the axis point \([x']\) of \( L_{[x'],[y']} \in C(m + t, N) \) the inequality
\[
y' = m + t - x' > m + t - \frac{m \log(\log m)^2}{\log m} = m \left(1 - \frac{\log(\log m)^2}{\log m}\right) + t \\
\sim m + t \geq p_{\pi(m)} = w
\]
for \( t \geq 4 \) and by appealing to Lemma 12.17 also the following asymptotic inequalities
\[
m - w \sim \frac{m \log \log m}{\log m} < x'
\]
and
\[
|y' - w'| = |(m + t - x') - w| = |m - w + t - x'| \lesssim |x' + t - x'| = t.
\]
Then the requirements in Theorem 12.11 are fulfilled asymptotically in this case with
\[
y' \gtrsim w \text{ and } x' \gtrsim m - w \text{ and } 0 \lesssim |y' - w| \lesssim t.
\]
In the case
\[ w' = \max\{ u \in ||C(m, N)|| \mid u \in \mathbb{P} \cup 2\mathbb{P} \} = 2p_{\pi(m/2)} \]
then we choose a prime number \( x < \frac{m \log(\log m)^2}{\log m} \) such that \( x > \frac{m \log \log m}{\log m} \), since by Bertrand’s postulate (Lemma 12.13) there exists a prime number \( x \) such that \( x \in (k, 2k) \) for every \( k > 1 \). Then we get for the axis partner \([y]\) of the axis point \([x]\) of \( L_{[x],[y]} \in C(m + t, N) \) the inequality
\[
y = m + t - x > m + t - \frac{m \log(\log m)^2}{\log m} = m \left(1 - \frac{\log(\log m)^2}{\log m}\right) + t \\
\sim m + t \geq p_{\pi(m)} \sim 2p_{\pi(m/2)} = w'
\]
for \( t \geq 4 \) and by appealing to Lemma 12.18 also the following asymptotic inequalities
\[
m - w' \sim \frac{m \log \log m}{\log m} < x
\]
and
\[
|y - w'| = |(m + t - x) - w'| = |m - w' + t - x| \lesssim |x + t - x| = t.
\]
Then the requirements in Theorem 12.11 are fulfilled asymptotically in this second case with
\[
y \gtrsim w' \text{ and } x \gtrsim m - w' \text{ and } 0 \lesssim |y - w'| \lesssim t.
\]
The result follows by arbitrarily choosing $t \geq 4$ so that $C(m + t, \mathbb{P} \cup 2\mathbb{P}) \neq \emptyset$ and adapting the proof in Theorem 12.11. □

Theorem 12.15 as well as Theorem 12.19 is equivalent to the statement: there must exist some positive constant $N$ such that for all $m \geq N$, then it is always possible to partition every even number $m$ as a sum of two primes resp. odd number as a sum of a prime and a double of a prime. This result - albeit constructive to some extent - looses its constructive flavour so that we cannot carry out this construction to cover all odd numbers, since we are unable to obtain any quantitative (lower) bound for the threshold $N$. At least, we are able to get a handle on the conjecture asymptotically.
