Abstract. The pionic contribution to the \( g - 2 \) of the muon involves a certain integral over the the modulus squared of \( F_\pi(t) \), the pion electromagnetic form factor. We extend techniques that use cut-plane analyticity properties of \( F_\pi(t) \) in order to account for present day estimates of the pionic contribution and experimental information at a finite number of points in the space-like region. Using data from several experiments over a large kinematic range for \(|t|\), we find bounds on the expansion coefficients of \( F_\pi(t) \), sub-leading to the charge radius. The value of one of these coefficients in chiral perturbation theory respects these bounds. Furthermore, we present a sensitivity analysis to the inputs. A brief comparison with results in the literature that use observables other than the \( g - 2 \) and timelike data is presented.

1 Introduction

General principles such as analyticity and unitarity have been used to derive useful constraints on form factors (for a review see ref. [1]). In particular, useful lower bounds were obtained on the pionic contribution to the \((g - 2)\) of the muon (muon anomaly). For recent reviews on the current status of this quantity, see refs. [2,3]. Consider the following low-energy expansion for the pion electromagnetic form factor \( F_\pi(t) \),

\[
F_\pi(t) = F_\pi(0) + \frac{r^2}{6} t + c t^2 + d t^3 + \cdots, \tag{1}
\]

where \( r_\pi \) is the pion charge radius, \( c \) and \( d \) are Taylor coefficients, with units of GeV\(^{-4}\) and GeV\(^{-6}\) respectively. For a recent discussion, refer [4]. From general principles, discussed in the next section, and using the normalization \( F_\pi(0) = 1 \), immediately gives a lower bound of \( \approx 1.6 \times 10^{-9} \). Imposing the experimental value of \( r_\pi \) further improves the bound to \( 2.9 \times 10^{-9} \) [1]. Caprini [5] has more recently shown that if one were to assume that the pionic contribution is less than \( I = 75 \times 10^{-3} \), then these principles yield constraints on the higher expansion coefficients, \( c, d \) which translate into an allowed ellipse in the \( c - d \) plane. These results, as well as the results we present here, hold as long as the true pionic contribution is less than the value of \( I \) we have assumed. If the pionic contribution is indeed significantly smaller, then the true allowed region would be a proper subset of the region we isolate.

The inclusion of experimental data from the time-like region, the phase, the modulus, and the phase as well as the modulus each improves the bound on the muon anomaly [1]. Using \( I \) as an input, Caprini has used dispersive techniques and time-like data, and has considered other physical observables such as certain QCD polarization functions, in addition to the muon anomaly, to constrain further the allowed regions in the \( c - d \) plane [5]. We note that the parameter \( c \) itself has been determined to 2-loop accuracy in chiral perturbation theory [7] and has a value of 4.49 GeV\(^{-4}\), which is safely accommodated in the allowed ellipse of Caprini [5].

An important source of experimental information are the values of the electromagnetic form factor in the space-like region. These have been reported in electroproduction experiments conducted in the 1970’s (see refs. [8], [9], [10]). Raina and Singh [11] used this information to produce improved bounds on the muon anomaly (see also [12]). New experimental data is now available (see refs. [13], [14], [15] and [16]). In this work, we will make use of some of the data sets above.

Our main purpose in this work is to demonstrate that the framework of Raina and Singh can be effectively used to obtain constraints in the \( c - d \) plane, using the pionic contribution to the muon anomaly as an input. This is an algebraic framework, which is clear cut and transparent. It provides an important consistency check on the allowed regions isolated by Caprini.

In sec. 2 we briefly review the dispersive formalism and describe the implementation of space-like constraints and the method by which we isolate the region in the \( c - d \) plane. Here, we provide the theoretical framework and also a discussion on the present experimental status, as they are both required for this purpose. In sec. 3 we present our results using data from [8], [9], [10] and more recent data from [15] and [16]. We present a detailed discussion of our results and our conclusions in sec. 4.

1 Applications to form factors in semi-leptonic decays of such general methods in a modern context have also been recently considered [6].
2 Formalism

We recall the formalism presented in ref. [11]. The pion contribution to the muon anomaly is given by:

\[ a_\mu(\pi^+\pi^-) = \frac{1}{\pi} \int_{t_\pi}^{\infty} dt \rho(t)|F_\pi(t)|^2 \]  

(2)

where \( t_\pi = 4m_\pi^2 \) is the branch point of the pion form factor and

\[ \rho(t) = \frac{a^2m_\mu^2}{12\pi}(t - t_\pi)^{3/2}/t^{7/2}K(t) \geq 0 \]

(3)

where,

\[ K(t) = \int_0^1 du (1-u)u^2(1-u + \frac{m_\mu^2u^2}{t})^{-1}. \]

(4)

Using the following map from the \( t \)-plane, which is cut from \( t_\pi \) along the real \( t \) axis, to the complex \( z \)-plane (region \( |z| < 1 \)),

\[ \frac{z - 1}{z + 1} = \frac{t - t_\pi}{t_\pi}. \]

(5)

and the definitions:

\[ f(z) = F_\pi(t) \]  

(6)

\[ p(z) = \rho(t) \]

(7)

the pionic contribution to the muon anomaly can be written as

\[ a_\mu(\pi^+\pi^-) = \frac{1}{2\pi} \int_0^{2\pi} d\theta w(\theta)|f(e^{i\theta})|^2 \]

(8)

where,

\[ w(\theta) = 4m_\pi^2 \sec^2(\theta/2)\tan(\theta/2) \]  

\[ p(e^{i\theta}) \geq 0. \]

(9)

We now consider a function \( h(z) \) defined as:

\[ h(z) = f(z)w_\pi(z) \]

(10)

where,

\[ w_\pi(z) = \exp \left[ \frac{1}{4\pi} \int_0^{2\pi} d\theta \frac{e^{i\theta} + z}{e^{i\theta} - z} \ln w(\theta) \right]. \]

(11)

Then eqn. [8] can be written as:

\[ a_\mu(\pi^+\pi^-) = \frac{1}{2\pi} \int_0^{2\pi} d\theta |h(e^{i\theta})|^2 \]

(12)

Now \( h(z) \) is analytic within the unit circle \( |z| < 1 \) and for real \( z \), \( h(z) \) is real. Therefore \( h(z) \) can be expanded as follows:

\[ h(z) = a_0 + a_1z + a_2z^2 + \cdots \]

(13)

where \( a_0, a_1, \cdots \) are real coefficients. Therefore, in the analytic region, \( |z| \leq 1 \), \( a_\mu(\pi^+\pi^-) \) can be written as:

\[ a_\mu(\pi^+\pi^-) = a_0^2 + a_1^2 + \cdots \]

(14)

The expansion coefficients \( a_n \) can be obtained from a Taylor expansion of the function \( h(z) \) in terms of \( f(z) \) and \( w_\pi(z) \). The coefficients are given by

\[ a_0 = h(0) = w_\pi(0), \]

\[ a_1 = h'(0) = w'_\pi(0) + \frac{2}{3}t_\pi w_\pi(0), \]

\[ a_2 = \frac{h''(0)}{2!} = \frac{1}{2} \left[ w_\pi(0) \left( \frac{8}{3}t_\pi^2 - 32c t_\pi^2 \right) \right] \]

\[ + \frac{1}{2} \left[ 2w'_\pi(0) \left( \frac{2}{3}t_\pi^2 \right) + w''_\pi(0) \right], \]

(15)

and

\[ a_3 = \frac{h'''(0)}{3!} = \frac{1}{6} \left[ w_\pi(0) \left( 12t_\pi^2 t_\pi - 384c t_\pi^2 + 384d t_\pi^2 \right) \right] \]

\[ + \frac{1}{6} \left[ 3w'_\pi(0) \left( \frac{8}{3}t_\pi^2 - 32c t_\pi^2 \right) \right] \]

\[ + \frac{1}{6} \left[ 2w''_\pi(0) r_\pi t_\pi + w'''_\pi(0) \right]. \]

(16)

In our treatment, the expansion coefficients satisfy

\[ \sum_{i=0}^{\infty} a_i^2 = I \]

(19)

Given \( I \), eqn. [19] yields constraints on the expansion coefficients of the form factor. Including up to the second (third) derivative for \( F_\pi(t) \) results in constraints for \( c \) (\( c \) and \( d \) ). It may be pointed out that Caprini’s result on \( c \) and \( d \) shown in Fig. 1 (dashed lines) of ref. [5] is obtained precisely in this manner.

The constraints on the expansion coefficients of interest may be significantly improved through the inclusion of experimental information on the form factor. Our objective in this work is to study the effect of including experimental information coming from the space-like region. In order to meet this objective, we first extend the formalism that has been presented in ref. [11]. In that work, space-like constraints were used to obtain lower bounds on the muon anomaly, denoted as \( I_{\text{min}} \).

We observe that \( N \) space-like constraints are linear constraints that may be expressed as:

\[ A_n = \sum_{i=0}^{\infty} a_i c_i^{(n)} \]

(20)

where \( n = 1, 2, \cdots N \). Such constraints can be implemented through the technique of Lagrange multipliers, by setting up the Lagrangian

\[ L = \frac{1}{2} \sum_{i=0}^{\infty} a_i^2 + \sum_{n=1}^{N} \alpha_n (A_n - \sum_{i=0}^{\infty} a_i c_i^{(n)}) \]

(21)

where eqn. [24], we consider only finite number of expansion coefficients. The Lagrange equations yield:

\[ a_i = \sum_{n=1}^{N} \alpha_n c_i^{(n)} \]

(22)
and
\[ I = \sum_{n=1}^{N} \alpha_n \sum_{i=0}^{\infty} a_i c_i^{(n)}. \] (23)

It then follows that
\[ I_{\text{min}} = \sum_{n=1}^{N} \alpha_n A_n, \] (24)

where
\[ A_n = \sum_{m=1}^{N} \alpha_m \sum_{i=0}^{\infty} c_i^{(m)} c_i^{(n)}. \] (25)

All the \( \alpha_n \)'s may be eliminated to yield a determinantal equation for \( I \)
\[
\begin{vmatrix}
I & A_1 & A_2 & \ldots \\
A_1 & \sum c_i^{(1)} c_i^{(1)} & \sum c_i^{(1)} c_i^{(2)} & \ldots \\
A_2 & \sum c_i^{(2)} c_i^{(1)} & \sum c_i^{(2)} c_i^{(2)} & \ldots \\
& \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
& \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\end{vmatrix} = 0. \] (26)

For the case at hand, where we wish to specify \( a_0, a_1, a_2, a_3 \) and the value at space-like points \( h(x_i), i = 1, 2, 3, \ldots \), where \( x_i \) is real, the determinantal equation reads,
\[
\begin{vmatrix}
I & a_0 & a_1 & a_2 & a_3 & h(x_1) & h(x_2) & \ldots \\
a_0 & 1 & 0 & 0 & 0 & 1 & 1 & \ldots \\
a_1 & 0 & 1 & 0 & 0 & x_1 & x_2 & \ldots \\
a_2 & 0 & 0 & 1 & 0 & x_2 & x_3 & \ldots \\
a_3 & 0 & 0 & 0 & 1 & x_3 & x_4 & \ldots \\
h(x_1) & 1 & x_1 & x_2 & x_3 & (1-x_1^2)^{-1} & (1-x_1x_2)^{-1} & \ldots \\
h(x_2) & 1 & x_2 & x_3 & x_4 & (1-x_2x_1)^{-1} & (1-x_2^2)^{-1} & \ldots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \\
\end{vmatrix} = 0. \] (27)

In the above merely retaining the first two rows and columns gives the first bound of Palmer, given in the Introduction, while retaining the first three rows and columns yields the second of Palmer’s bounds. Raina and Singh [11] use the value of \( F_\pi(0) = 1 \) and \( r_\pi \) to obtain the lower bound to \( a_\mu(\pi^+\pi^-) \). This amounts to dropping out the rows and columns corresponding to \( a_2 \) and \( a_3 \) in eqn. (27) which are related to the expansion coefficients \( c \) and \( d \). Instead, providing an input to \( I \) in eqn. (27) gives us an allowed region in the \( c-d \) plane. Dropping the row and column corresponding to \( a_3 \) would result in determining an allowed region for \( c \) alone, which we pursue in the next section for purposes of illustration.

In the next subsection, we provide a discussion on the present day experimental information that is utilized in our study. This information spans an impressive range of energies, viz. \( |t| \). While in principle there is no limit to the number of constraints, in practice the uncertainties in the experimental determination and sensitivity of the determinantal equation limits this number. The reason for such restrictions is the extreme sensitivity of the matrices to these experimental uncertainties as their dimensions increase. This sensitivity is particularly acute for small values of \( |t| \). As a result, at such values we are able to implement at most two constraints, while data from higher energies allows us to implement up to three constraints. However, the data from smaller values of \( |t| \) provide more stringent bounds for fixed number of constraints. Thus we see a rather complex interplay between the energy regime that we can use and the number of constraints we are able to implement.

### 2.1 Space-like data

We will begin with the data in the space-like region that was used in the work of Raina and Singh [11], that came from measurements in the seventies. We refer to these as the Brown data and Bebek data respectively. The data we use from these sets is given in Tables 1-2. The tables also list the values of \( z(t) = x(t) \), which is the map from the \( t \) plane to the disc \( |z| \leq 1 \) \((x(t) \in \text{the range } \{-1 \leq x(t) \leq 0\})\), for the chosen data points and the corresponding value of \( h(z) = h(x) \) (refer eqn. (10)). To make our notations clear, we refer to the data points corresponding to a particular \( |t| \) as \( x_1, x_2 \) and so on, in the ascending order of magnitude of \( |t| \). The tables also show the experimental errors in the data.

More recent data come from four sources. The first of these is ref. [13] which is from a Fermilab experiment (F1). Here the range is \( 0.03 \text{GeV}^2 \leq -t \leq 0.07 \text{GeV}^2 \). Even at the high end, we are way below the lowest energy of Brown. The next set of data come from another Fermi lab experiment (F2) (ref. [14]), covering the range of \( 0.037 \text{GeV}^2 \leq -t \leq 0.094 \text{GeV}^2 \). The CERN NA7 experiment provides very accurate data [15] in the range \( 0.014 \text{GeV}^2 \leq -t \leq 0.26 \text{GeV}^2 \) (by Amendolia et al). There is an overlap region between this last set and the Brown data and the two are consistent. The final data we use come from the JLab experiments (Tadevosyan et al., ref. [16]).

In our study we choose to work with recent data from Amendolia et al. [15] that cover both the low and intermediate energy range (note that the data from [13] cover a smaller energy range; hence our choice) and the data from the JLab experiments (Tadevosyan et al., ref. [16]) that cover a higher range of \( |t| \). Using really small \( |t| \) values lead to numerical instabilities as the entries in the determinant (eqn. (27)) become small.

Tables 1-4 show the data that is used in our analysis to constrain the expansion coefficients \( c \) and \( d \) of the form factor \( F_\pi(t) \). The data from various experiments are chosen so as to give reliable numerical results. We find data in lower \( |t| \) to constrain the expansion coefficients better but we cannot include more than two space-like constraints; while the higher \( |t| \) region gives a weaker bound, which can be improved by increasing the number of space-like constraints.
3 Results

In our results, we use \( I = 75 \times 10^{-9} \) as an input, as quoted in \(^5\). This value is certainly greater than a recent estimate for the hadronic contribution to \( a_\mu^{\text{had}} = 69.2 \times 10^{-9} \) given in \(^5\). Pionic contribution is expected to be around 70% of the total hadronic value. Our value for \( I \) gives a conservative upper bound to the pionic contribution to \( a_\mu \).

We begin by constraining only the expansion coefficient \( c \) which amounts to dropping out the row and column corresponding to \( a_3 \) in eqn. \(^{27}\). We determine the bounds on \( c \) in stages, starting with only the pion charge radius \( r_\pi \) and the normalization of \( F_\pi(t) \) at \( t = 0 \) (i.e., no space-like constraints) and then incorporate space-like constraints successively. The results are shown in fig. 1, where we have used data from tables 1, 2, 3 and 4. For any data set, we start with the smallest value of \(|t|\) for one space-like constraint and include more constraints in increasing magnitude of \(|t|\). All the data sets show the trend that inclusion of more space-like constraints in this manner, improve the bounds on \( c \). The largest range for \( c \) in units of GeV\(^{-4} \) is obtained when no space-like constraints are used. This agrees with the result of Caprini (fig.1 in \(^3\)). Note however, that for data from larger values of \(|t|\), the bound on \( c \) is significantly weaker, compared to data from smaller values of \(|t|\) for a fixed number of space-like constraints.

It is worth investigating the sensitivity of the bounds to the errors in the input data. The Brown data shifts the bounds on \( c \) to negative values when two space-like constraints are used. This shift is sensitive to the error bounds on \( F_\pi \). If we use as input \( F_\pi(t_1) + 0.028 \) (table 2) for the first constraint and \( F_\pi(t_2) - 0.013 \) for the second constraint, then the upper bound on \( c \) is positive. Here, \( t_1 \) and \( t_2 \) represent the first and second data point respectively in table 2. We present further sensitivity analysis later in this section. Similarly for the data from Amendolia et.al \(^15\), we see that one space-like constraint can be incorporated using central values for \( F_\pi(t) \); but varying this input over the error bounds given in table 4, we can use up to two constraints (not shown here). Unless otherwise specified, all results presented in this section use the central values of the form factor data given in tables 1, 2, 3 and 4.

Including constraints from \( a_3 \) results in a relationship between the expansion coefficients \( c \) and \( d \) which we shall now explore. Fig. 2 shows the allowed region in the \( c - d \) plane using only the normalization condition on \( F_\pi(t) \) and the value of \( r_\pi \). Analogous to the study of the bounds on \( c \), we can include space-like constraints to impose stringent bounds on the expansion coefficients \( c \) and \( d \), that are reflected by smaller allowed regions in the \( c - d \) plane.

### Table 1. Space-like data from Bebek et al. \(^{10}\)

| \( t(-Q^2) [\text{GeV}^2] \) | \( F_\pi(t) \) | \( x(t) \) | \( h(x) \times 10^{-5} \) |
|----------------|-------------|---------|----------------|
| 1 -0.620     | 0.453 ± 0.014 | -0.499  | 3.057 |
| 2 -1.216     | 0.292 ± 0.026 | -0.606  | 2.035 |
| 3 -1.712     | 0.246 ± 0.017 | -0.655  | 1.716 |

### Table 2. Space-like data from Brown et al. \(^9\)

| \( t(-Q^2) [\text{GeV}^2] \) | \( F_\pi(t) \) | \( x(t) \) | \( h(x) \times 10^{-5} \) |
|----------------|-------------|---------|----------------|
| 1 -0.294     | 0.606 ± 0.028 | -0.372  | 3.775 |
| 2 -0.795     | 0.380 ± 0.013 | -0.540  | 2.608 |

### Table 3. Space-like data from Tadevosyan et al. \(^{10}\)

| \( t(-Q^2) [\text{GeV}^2] \) | \( F_\pi(t) \) | \( x(t) \) | \( h(x) \times 10^{-5} \) |
|----------------|-------------|---------|----------------|
| 1 -0.600     | 0.433 ± 0.017 | -0.494  | 2.915 |
| 2 -1.000     | 0.312 ± 0.016 | -0.576  | 2.163 |
| 3 -1.600     | 0.233 ± 0.014 | -0.645  | 1.626 |

### Table 4. Space-like data from Amendolia et al. \(^{15}\)

| \( t(-Q^2) [\text{GeV}^2] \) | \( F_\pi(t) \) | \( x(t) \) | \( h(x) \times 10^{-5} \) |
|----------------|-------------|---------|----------------|
| 1 -0.131     | 0.807 ± 0.015 | -0.242  | 4.454 |
| 2 -0.163     | 0.756 ± 0.016 | -0.275  | 4.286 |
Fig. 1. Constraints on $c$ starting with just information on $F_\pi(0) = 1$ and $r^2_\pi$ and incorporating space-like constraints. Note that the allowed values of $c$ decrease as we include more space-like constraints.

Fig. 2. Constraints on $c$ and $d$ using the normalization $F_\pi(0) = 1$ and the pion charge radius $r_\pi$. 
Fig. 3. Constraints on $c$ and $d$ using one space-like constraint. Here we start with the smallest $|t|$ value and the corresponding value of $h(z) = h(x_1)$ and study the variation of the bounds on $c$ and $d$ as we use data from higher the $|t|$ region.

Fig. 4. Constraints on $c$ and $d$ as the number of space-like constraints are increased. Here the space-like data is taken from refs. [10], [16].
Fig. 5. Constraints on \( c \) and \( d \) as the number of space-like constraints are increased. Here the space-like data is taken from refs. [9], [15].

Fig. 3 shows the variation in the bounds on \( c \) and \( d \) for one space-like constraint, where data from different \(|t|\) region is used. In the figure, \( h(x_1) \) is the value of \( h(x) \) as defined in eqn. (10) corresponding to the smallest value of \( t \) in each data set (refer tables [11]-[14]). Similarly \( h(x_2) \) is the constraint at a higher \(|t|\) value taken in the ascending order of magnitude. It may be readily observed that the most stringent bounds are obtained when data from smallest values of \(|t|\) are used, and they improve as the number of constraints are increased, as noted earlier.

Fig. 4 (as well as fig. 5) shows that increasing the number of space-like constraints improves the bounds on the expansion coefficients \( c \) and \( d \). We observe that the allowed range for \( c \) corresponds to that in fig. 1. Using the central values tabulated in tables [11]-[14] we see that we are able to use up to three space-like constraint with the data from Bebek et al. [10] and the recent data from Tadevosyan et al. [16], while we are able to incorporate only two space-like constraints with the data from Brown et al. [9] and one with the data from Amendolia et al. [15]. The best estimate for the bounds on the Taylor coefficient \( c \) and \( d \) is obtained for the data from Bebek et al. [10].

But varying the Bebek data within the error bounds, we see that there is overlap with the bounds obtained with the data from Tadevosyan et al. [16], as seen in fig. 6. In fig. 6, the label “max” refers to the data taken from the tables [11]-[14] with the corresponding error bounds added, i.e. at the upper limit of the error bound, central refers to the central values and “min” refers to central value minus the error bound, i.e., the lower limit of the error bound. We see that an overlap between the bounds obtained from the different data set occurs when the data are close to the upper error bound. In fact at the upper error bound, the data from Tadevosyan et al. gives better bounds on the expansion coefficients compared to the data from Bebek et al. At the central value of \( F_{\pi}(t) \), the data from Bebek et al. does better while at the lower end, the data from Bebek et al., no longer yields stable result, while the data from Tadevosyan et al. still gives reasonable bounds. We find that despite small differences in the allowed regions, the fact that the allowed regions are essentially the same offers an important consistency check on the form factor determinations by each of the experiments.

As seen from the our results so far, the bounds on the Taylor coefficients vary due to the errors in the data presented in the tables [11]-[14] hence it is important to examine the sensitivity of our results to the inputs. We have made a systematic study of the sensitivity by varying, (a) the input value of \( r_\pi \), (b) the input value of \( I \), and (c) varying the experimental determinations of \( F_{\pi}(t) \) within their quoted errors, and in each instance keeping all other inputs fixed.

Variations in the bounds on \( c \) and \( d \) for one space-like constraint from [10], [15], when the value of \( r_\pi \) is var-
ied within the error bounds quoted therein, is shown in fig. (7). We see that the bounds do not vary much as $r_\pi$ is varied within the allowed errors of a few percent. Fig. (8) shows the variations in the bounds of $c$ and $d$ as the value of $I$ is changed. Lower $I$ values result in a subspace of the region allowed for the coefficients at higher $I$ values. We expect this behavior as our method gives only an allowed region for the coefficients. This explicitly demonstrates that as long as the true pionic contribution is lower than the values we have used, the allowed region lies within the isolated ellipse.

Fig. (9) shows the variations bounds on $c$ and $d$ for the data from Amendolia et al. [15] and Bebek et al. [10] for one space-like constraint (smallest magnitude of $|t|$ in the tables 1 and 4). The data are varied within their experimental bounds and the results are depicted in fig. (9). We see that the bounds on the expansion coefficients are most sensitive to errors in the data from lower $|t|$. Having said that, it is our view that one may read-off reliable ranges for both $c$ and $d$ in light of this sensitivity analysis. However an analogous sensitivity test that we have carried out for two space-like constraints for the data from Amendolia et al. [15] leads to a complete loss of coherence. This is an unavoidable numerical difficulty in the determinant that arises due to the fact that the entries are small and closely spaced. Therefore we can conclude that for low $|t|$ information we are unable to obtain reliable results for more than one constraint.

We explore this sensitivity of the bounds to the data taken from the low $|t|$ region using one space-like constraint from [15] and varying this constraint over the given error bounds (Table 1) and study the corresponding variations in the bounds on $c$ alone. This is seen in fig. (10) where the circles represent the maximum and the squares represent the minimum of the bounds. The filled symbols stand for the bounds obtained from the data at lower value of $|t|$ and the open symbols represent those from the data at higher value of $|t|$. Fig. (11) shows similar variations in the bounds on $c$ when one as well as two space-like constraints (ref. table 3) for the data taken from [16] are varied over the error bounds. Note that the data from [16] lie at higher $|t|$ value compared to the data from [15]. When two space-like constraints are used, we fix one constraint at the central value and vary the other over the error bounds quoted in [16] and plot the maximum and minimum of the bounds as a function of the constraint that is varied. From figs. (10) and (11), we see that data from lower $|t|$ value in each set constraints the coefficients better for one space-like constraint. Also the sensitivity to the error bounds is greater for a set at lower $|t|$ compared to the set at higher value of $|t|$. We also note that two space-like constraints are more sensitive to the variations in $F_\pi(t)$ compared to one space-like constraint, as can be seen in fig. (11).

Relative errors in the bounds on $c$ as one space-like constraint is varied over the quoted error bounds com-
pared to the bounds obtained from the central value is shown in fig. (12) for the data sets from Amendolia et al. and Tadevosyan et al.. We see that relative errors are smaller for the data from Tadevosyan et al., once again emphasizing our earlier observation that the sensitivity of the Taylor coefficients to the errors in the determination of $F_\pi(t)$ is greater for the data from the low $|t|$ region compared to those from the high $|t|$ region.

Fig. 7. Variations in the bounds on $c$ and $d$ when the value of $r_\pi$ is changed. This has been carried out for one space-like constraint for the data set by Amandolia et al. [15]

Fig. 8. Variations in the bounds on $c$ and $d$ when the value of $I$ is changed. This has been carried out for one space-like constraint for the data set by Amandolia et al. [15].

Fig. 9. Variations in the bounds on $c$ and $d$ when the data for $F_\pi(t)$ from tables [1] and [4] are varied within their error bounds. Here “central” refers to the value without the errors and “min” to lowest value and “max” to the highest value within the error bounds. Note that the bounds are more sensitive to the errors in the data from the small $|t|$ region.

4 Discussion and Conclusions

In this work we have considered the constraints on the pion electromagnetic form factor coming from present day estimates of the pionic contributions to the muon anomaly, and from space-like data which is available over a fairly extended kinematic regime. We have adopted the framework of Raina and Singh and have extended it to obtain constraints on $c$ and $d$, the expansion coefficients sub-leading to the charge radius of the pion. We have used data available in the 1970’s (also used in ref. [11]) and more recent data which spans significantly lower values of $|t|$, as well as very recent data coming from Tadevosyan et al. which are at higher $|t|$ values, which lie in the range of Bebek et al.

As mentioned in the Introduction, Caprini [5] has used timelike data to obtain constraints on the Taylor coefficients. By systematically considering the inclusion of only the phase, the ellipse with no constraints was found to shrink considerably using as an observable the QCD polarization function (see figs. (1) and (2) in [5]). This analysis employs an optimal technique, resulting in an integral equation of the Fredholm type that was solved numerically. The ellipse was found to shrink even further when both the phase as well as the modulus information were used even though the technique was non-optimal (see
Questions remain about its validity due to certain mathematical difficulties, as discussed by Caprini. The best estimates for the bounds on \( c \) and \( d \) is obtained using the data from Bebek et al. [10] for three space-like constraints. In fig. 11, we compare our best result with those obtained by Caprini using only the phase from the timelike region. Using space-like data we get the following range for the expansion coefficients: \(-1 \text{ GeV}^{-4} \lesssim c \lesssim 11 \text{ GeV}^{-4} \) and \(-132 \text{ GeV}^{-6} \lesssim d \lesssim 220 \text{ GeV}^{-6} \). On the other hand Caprini has a range of \([-14 \text{ GeV}^{-4}, 44 \text{ GeV}^{-4}]\) and \([-236 \text{ GeV}^{-6}, 594 \text{ GeV}^{-6}]\) for \( c \) and \( d \) respectively using only the phase of timelike data. It is interesting to note that the overlap region between the two determinations, ours using space-like data and the muon anomaly and Caprini’s using the phase of timelike data and the QCD polarization observable, accommodates comfortably the value of \( c \) from chiral perturbation theory. We note here that similar bounds obtained using the central values of the Tadevosyan data (ref. table 3) using three space-like constraints does not accommodate the value of \( c \) obtained from chiral perturbation theory, but varying the data at the upper end of the error bound, as in fig. 6, the allowed region does include this value.

Our conclusions are that the constraints are weaker than those obtained by Caprini using both phase and modulus of data from the timelike region (see fig.(3) in [6]), while they are more stringent than those obtained with only the phase of the timelike data. Here we note again, that the latter of these treatments is rigorous and the results may be taken as reliable. On the other hand, the results obtained from using both the modulus and phase while appearing more stringent are on a less rigorous foot-
We have also carried out a sensitivity analysis by varying the estimate for the pionic contribution over a significant range, varying the charge radius over its presently known errors, and also by varying the experimental data that we use over its errors, for the values of $|t|$ that we have chosen. Our conclusions are that in the small $|t|$ region, the system is very sensitive and as a result, we have been unable to implement anything more than one space-like constraint. For larger values, we are able to include two and even three constraints.

Of related interest, is the extreme sensitivity of the system when bounds are being derived on the muon anomaly from space-like data, as recognized earlier by Pantea and Raszillier [17]. The issue was of some significance because several space-like constraints were being used to obtain these bounds. Our circumstances are somewhat mitigated by the fact that we are using significantly smaller number of constraints, as the determinantal equations we are solving are already of rather large dimensions. By studying the sensitivity of the bounds, we are confident that our results remain stable.

It is conceivable that as data improves one may obtain better constraints on $c$ and $d$, where it is numerically feasible, that can then be used as inputs for high precision, self-consistent form factor determinations. We also note at this point that our work takes into account only the information present in the space-like region. It would be worth-while to properly formulate the problem so that the information available in the timelike region could be incorporated together with a comprehensive error analysis.

A theory of error functionals has been developed by Raina and Singh [18] in the context of finding a lower bound for the muon anomaly, that could in principle be extended for the problem at hand, which is beyond the scope of this work. Therefore, future investigations could combine highly accurate phase and modulus timelike information coming from recent experiments and the techniques developed by Caprini for the phase problem, together with a suitable extension of the error functional method, to produce stringent constraints on $c$ and $d$.

We are indebted to I. Caprini for careful reading and comments on the manuscript and several patient discussions. We also thank G. Colangelo, H. Leutwyler, B. Moussallam and A. Upadhyay for discussions. BA thanks the Department of Science and Technology, Government of India, for support. BA also thanks V. Singh for drawing attention to refs. [1], [11] and [13].
