Motivated by recent results from neutrino experiments, we study the neutrino masses and mixing in the framework of a SUSY $SU(5) \times A_4$ model. The hybrid of Type I and Type II seesaw mechanisms leads to the nonzero value of the reactor angle $\theta_{13} \neq 0$ and to the recently disfavored maximal atmospheric angle $\theta_{23} \neq 45^\circ$ by the NOvA experiment. The phenomenological consequences of the model are studied for both normal and inverted mass hierarchies. The obtained ranges for the effective Majorana neutrino mass $m_{\beta\beta}$, the electron neutrino mass $m_{\nu_e}$, and the $CP$ violating phase $\delta_{CP}$ lie within the current experimental allowed ranges where we find that the normal mass hierarchy is favored over the inverted one.

Key words: Neutrinos mixing, SUSY $SU(5) \times A_4$, Hybrid Seesaw.

1. INTRODUCTION

The neutrino oscillation experiments performed in the past two decades provided many decisive evidences of nonzero neutrino masses and large neutrino mixing \[ \[1-6\]. The atmospheric, solar, and reactor neutrino experiments have provided the measurements of the mass-squared differences $\Delta m^2_{ij}$ as well as the mixing angles $\theta_{ij}$; the current neutrino oscillation data can be found in the latest global fit analysis \[7-9\]. To understand the origin of these masses—which are very tiny—and mixing, we must go beyond the standard model (SM) that predicts massless neutrinos. Theoretically, the most prominent way to generate such tiny masses for neutrinos is through the famous seesaw mechanism, which requires the introduction of extra heavy fermions (Type I and Type III seesaws) or scalars (Type
II seesaw) into the SM \([10, 11]\), giving rise to neutrino masses of Majorana type. For the
neutrino mixing angles, it was not until 2012 that the reactor angle \(\theta_{13}\) was discovered to
be different from zero \([3]\), but unlike the other two mixing angles \(\theta_{12}\) and \(\theta_{23}\), its value is
relatively small. Furthermore, the NOvA experiment has disfavored recently the maximal
atmospheric neutrino mixing \(\sin^2 \theta_{23} = 0.5\) \([12]\); however, whether its value is less or greater
than \(\pi/4\) is yet to be discovered. In the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) ma-
trix that describes these angles, \(\theta_{13}\) always appears in combination with the Dirac phase,
and thus, the discovery of its nonzero value has a crucial influence on the Dirac \(CP\) violat-
ing (CPV) phase \(\delta_{CP}\) where its measurement is the ultimate objective of the long baseline
neutrino oscillation experiments \([13]\). The recent progress in neutrino physics motivated
theoretical as well as experimental physicists to search for new physics beyond the SM. This
concerns the preexisting theories and models such as supersymmetric grand unified theories
(SUSY GUTs) which unlike the non-SUSY GUTs solve the hierarchy problem and unifica-
tion of gauge couplings just by introducing supersymmetry; thus, they are adopted as one
of the most appealing extensions of the SM \([14]\). Moreover, an attractive way to outline the
observed neutrino mass hierarchies and mixing within SUSY-GUT models is through dis-
crete flavor symmetries. Indeed, several models beyond SM have used different non-Abelian
groups and described successfully all the neutrino mixing angles; see Table 3 of Ref. \([15]\)
and Ref. \([16]\). In fact, these non-Abelian discrete groups are widely adopted to describe the
large mixing angles in the lepton sector. In particular, these groups lead to a specific form of
the neutrino mass matrix which is consistent with tribimaximal mixing (TBM). This special
mixing induces \(\theta_{13} = 0\) and \(\theta_{23} = \pi/4\); however, it is now ruled out by the discovery of the
nonzero reactor angle as mentioned above. Thus a small deviation from TBM is required
to reconcile with the small value of \(\theta_{13}\) as well as a small deviation from the maximal value
of the atmospheric angle \(\theta_{23}\). In this regard, several ways have been proposed to generate
a small deviation of these mixing angles. For example, the deviation from TBM in flavor
symmetry-based models can arise from (i) the diagonalization of the charged lepton mass
matrix \([17]\), (ii) perturbing the vacuum expectation value (VEV) alignment \([18]\), (iii) the
Yukawa sector \([19]\), or (iv) the Majorana sector \([16, 20]\). These deviations are generally real-
ized by introducing next-to-leading-order effective operators while the leading contribution
is produced by one of the seesaw mechanisms. On the other hand, it was claimed in Ref.
\([21]\) that the required deviations from the TBM matrix can be interpreted as the interplay
of two different seesaw mechanisms making what is known as hybrid neutrino masses. This
hybrid has been used by many authors to account for the nonzero reactor angle \(\theta_{13} \neq 0\) in
the framework of the SM and GUTs; see, for example, Ref. [22].

In this paper we propose a neutrino model in the framework of a supersymmetric $SU(5)$ GUT extended by three right-handed neutrinos $N_i$ and a 15-dimensional Higgs $H_{15}$ transforming respectively as a triplet and a nontrivial singlet under $A_4$ flavor symmetry. The theoretical predictions of our proposal concerning the mixing angles and masses are compatible with the latest neutrino experimental data. The main line of our proposal is as follows: First, we consider SUSY $SU(5) \times A_4$ theory and generate the neutrino mass matrix by the hybrid seesaw mechanism. In this hybrid, the dominant mass contribution comes from Type I seesaw, leading to the TBM [23]. A small perturbation responsible for nonzero reactor angle $\theta_{13}$ and nonmaximal atmospheric angle $\theta_{23}$ is realized by the 15-dimensional $SU(5)$ Higgs that contains an $SU(2)_L$ Higgs triplet $\Delta_d$ via Type II seesaw mechanism. Then, we perform a numerical study, where we use the experimental allowed ranges of the mixing angles and the mass-squared differences, to examine the octant degeneracy of $\theta_{23}$ for both normal and inverted mass hierarchies. Next, we use the current neutrino oscillation data as well as the cosmological limit on the sum of neutrino masses to study the phenomenological consequences of our proposal for both normal and inverted mass hierarchies. We find that the allowed ranges of the effective Majorana neutrino mass $m_{ee}$, the sum of neutrino masses $\sum_{i=1}^{3} |m_i|$, the effective electron neutrino mass $m_\beta$, and the Dirac CPV phase $\delta_{CP}$ are within the current experimental data.

To perform this study, we use known results on SUSY $SU(5)$ as well as properties of the alternating group $A_4$. This flavor symmetry is generally admitted as the most natural and economical discrete group that captures the family symmetry as motivated in the literature [24]. The discrete $A_4$ possesses two generators $S, T$ and four irreducible representations that can be labeled by their characters as $1_{(1,1)}, 1_{(1,\omega)}, 1_{(1,\omega^2)},$ and $3_{(-1,0)}$. These four representations, which are related to the $A_4$ group order by the formula $1_{(1,1)}^2 + 1_{(1,\omega)}^2 + 1_{(1,\omega^2)}^2 + 3_{(-1,0)}^2 = 12$, are also used to host the matter and Higgs content of the SUSY $SU(5) \times A_4$ proposal. For general properties on $A_4$ group representations and their characters, see [25, 26].

This paper is organized as follows. In Sec. 2, we present the superfield content for the neutrino sector in SUSY $SU(5) \times A_4$. Then, we study the Dirac and Majorana neutrino mass matrices as well as the deviations of $\theta_{13}$ and $\theta_{23}$ from their TBM values. In Sec. 3, we study the phenomenological implications of the proposal and provide the predictions regarding the effective Majorana mass $m_{ee}$, the effective mass $m_\beta$, the sum $\sum_{i=1}^{3} |m_i|$, and the CPV phase $\delta_{CP}$. In Sec. 4, we give our conclusion. In order to make the paper more self-contained we add Appendix A on the charged sector where we show that a $U(1)$ flavor
symmetry is needed to control the couplings of the model. We also add in the same appendix a brief discussion on the well-known dangerous four- and five-dimensional operators leading to the rapid proton decay and show how they are suppressed in our model due to the flavor symmetry.

2. SU(5) GUT with $A_4$ Flavor Symmetry

In this section, we first describe the superfield content of our $SU(5) \times A_4$ GUT proposal. Then, we use a hybrid seesaw mechanism to study the deviation of the $\theta_{13}$ and $\theta_{23}$ angles in this proposal. After that, we study the mass-squared differences as functions of the space parameters of the model and the $\theta_{23}$ and $\theta_{13}$ mixing angles.

2.1. Implementing $A_4$ in Neutrino Sector

In supersymmetric $SU(5)$ GUT, matter superfields are unified into two irreducible representations of $SU(5)$ namely $10^i_m$ and $\bar{5}^i_m$ where $i = 1, 2, 3$ refers to the three possible generations of matter. On the other hand, the Higgs doublets $H_u$ and $H_d$ of the minimal supersymmetric standard model (MSSM) sit in representations $5_{H_u} = H_5$ and $\bar{5}_{H_d} = H_{\bar{5}}$.

Here we focus our attention on the neutrino sector in SUSY $SU(5)$ GUT promoted by an $A_4$ flavor symmetry. Thus, we give only the superfield content needed to generate the mass terms for the neutrinos. In our construction of SUSY $SU(5) \times A_4$ GUT, we proceed as follows:

(i) First, we extend the fermion sector of $SU(5)$ GUT by adding three right-handed neutrinos $N_i$ which are $SU(5)$ gauge singlets and sit together in the $A_4$ triplet $3_{-1,0}$. These $N_i$’s allow us to use the Type I seesaw formula $m_\nu^I = -m_D M^{-1}_R m_D^T$ to generate light neutrino masses. One $A_4$ flavon triplet superfield $\Phi$ is added to get a neutrino mass matrix $m_\nu^I$ consistent with the leading order TBM pattern. The addition of one flavon in the neutrino sector is actually the minimal setup if we consider only the four-dimensional $SU(5) \times A_4$ models that describe successfully all the mixing angles. Some of these models that used at least three flavon superfields in the neutrino sector are given in Ref. [27].

(ii) Second, we extend the Higgs sector of SUSY $SU(5)$ GUT by adding a $15$-dimensional Higgs $15_{\Delta_d} \equiv H_{15}$ which contains a $Y = 2$ $SU(2)_L$ Higgs triplet $\Delta_d$. This leads to a Majorana mass matrix $M_\nu^{II}$ via the Type II seesaw mechanism as exhibited by the Yukawa coupling $\bar{5}_m \otimes 15_{\Delta_d} \otimes \bar{5}_m$. When added to $m_\nu^I$, the matrix $M_\nu^{II}$ will play the role of a
perturbation inducing a deviation from the TBM values. Notice that $H_{15}$ has been first used in non-SUSY $SU(5)$ without flavor symmetry to achieve the gauge coupling unification and the generation of tiny neutrino masses\cite{28}. Notice also that the deviation from TBM by Type II seesaw mechanism with discrete flavor $A_4$ has also been considered in SM to reconcile with the experimental value of $\theta_{13}$\cite{29}. In our SUSY $SU(5) \times A_4$ proposal which extends this approach to supersymmetric GUT models building, we took into account the latest experimental results on neutrino masses and mixing, and we successfully produced the nonzero value of $\theta_{13}$ as well as the nonmaximal value of $\theta_{23}$.

So the superfield content of our proposal is as follows: (a) matter containing three generations of $\mathbf{5}_m$ denoted as $F_i$, $\mathbf{10}_m^i$ denoted as $T_i$, and the three right-handed neutrinos $N_i$. Below, we will mainly focus on $F_i$ and $N_i$ couplings relevant for neutrino sector, while the contribution of the $\mathbf{10}_m^i$'s in the charged lepton and quark sectors will be discussed in Appendix A. (b) The Higgs sector containing: (i) the two usual Higgses $H_5$ and $H_{\bar{5}}$ as well as the added $H_{15}$ and $H_{15}$; the $H_5$ and $H_{\bar{5}}$ are required by supersymmetry. (ii) The usual 24-dimensional adjoint Higgs $H_{24}$ needed to break the $SU(5)$ group to the standard model gauge group. (iii) An extra flavon chiral superfield $\Phi$ to generate the TBM matrix.

These superfields are the minimal set we need to generate neutrino masses and mixing compatible with experimental data. The quantum numbers of these superfields under $SU(5) \times A_4$ are as listed in Table I.

| Fields | $F_i$ | $T_1$ | $T_2$ | $T_3$ | $N_i$ | $H_5$ | $H_{\bar{5}}$ | $\Phi$ | $H_{15}$ |
|--------|-------|-------|-------|-------|-------|-------|-----------|-------|---------|
| $SU(5)$ | $\mathbf{5}_m^i$ | $\mathbf{10}_m^1$ | $\mathbf{10}_m^2$ | $\mathbf{10}_m^3$ | $\mathbf{1}_i^l$ | $5_{H_u}$ | $5_{H_d}$ | $1$ | $15_{\Delta d}$ |
| $A_4$ | $3_{-1,0}$ | $1_{(1,\omega)}$ | $1_{(1,\omega^2)}$ | $1_{(1,1)}$ | $3_{-1,0}$ | $1_{(1,1)}$ | $1_{(1,\omega)}$ | $3_{-1,0}$ | $1_{(1,\omega)}$ |

**TABLE I:** Superfield content and their quantum numbers under $SU(5) \times A_4$.

Besides $N_i$ and $\Phi$, which are gauge singlets, $T_i$, $F_i$, $H_5$, and $H_{15}$ are given in standard model representations as follows:

$$
\begin{align*}
SU(5) & \rightarrow SU(3)_c \times SU(2)_L \times U(1)_Y \\
\mathbf{5}_m^i & : (3, 1)_{2/3} + (1, 2)_{-1} = (D^c_i, L_i) \\
5_{H_u} & : (3, 1)_{-2/3} + (1, 2)_1 = (T_{u}, H_{u}) \\
15_{\Delta d} & : (1, 3)_2 + (3, 2)_{1/3} + (6, 1)_{-4/3} = (\Delta_d, \Delta'_d, \Delta''_d) \\
\mathbf{10}_m^i & : (3, 2)_{1/3} + (\bar{3}, 1)_{-4/3} + (1, 1)_2 = (Q_i, U^c_i, E^c_i)
\end{align*}
$$

(2.1)
where the decompositions of $5_{H_d}$ and $\overline{15}_{\Delta_u}$ are understood.

### 2.2. Deviation of $\theta_{13}$ and $\theta_{23}$ in $SU(5) \times A_4$ hybrid seesaw

We start with the leading approximation where the neutrino mass matrix is generated through Type I seesaw mechanism and is consistent with TBM predicting the mixing angles: $\sin^2 \theta_{12} = \frac{1}{3}$, $\sin^2 \theta_{23} = \frac{1}{2}$, and $\sin^2 \theta_{13} = 0$. Then, we make use of the 15-dimensional $SU(5)$ Higgs $15_{\Delta_d}$ that contains an $SU(2)_L$ Higgs triplet $\Delta_d$ leading to Majorana mass term via Type II seesaw mechanism. Hence, the total neutrino mass matrix combines both Type I and Type II seesaws, allowing a reconciliation with the experimental values of the mixing angles $\theta_{13}$ and $\theta_{23}$.

#### 2.2.1. TBM from Type I seesaw mechanism

The Type I seesaw formula incorporates both Dirac and Majorana mass matrices where the Dirac mass matrix $m_D$ is obtained from the superpotential term involving the couplings among the superfields $N_i$, $F_i$, and $H_5$ while the Majorana mass matrix $M_R$ is obtained from the superpotential involving the coupling of right-handed neutrinos $N_i$ with themselves. As we mentioned before, both $F_i$ and $N_i$ live in the $A_4$ triplet $3_{−1,0}$ while the Higgs $H_5$ is assigned to the trivial singlet. The leading order superpotential for neutrino Yukawa couplings respecting gauge and $A_4$ symmetries is given by

$$W_D = \lambda_1 N F H_5,$$  \hspace{1cm} (2.2)  

where $\lambda_1$ is a Yukawa coupling constant. Using the tensor product of $A_4$ irreducible representations in the Altarelli-Feruglio basis $[25,30]$, the superpotential (2.2) reads

$$W_D = \lambda_1 (N_1 F_1 H_5 + N_2 F_3 H_5 + N_3 F_2 H_5).$$  \hspace{1cm} (2.3)  

When the Higgs doublet develops its VEV as the usual $\langle H_u \rangle = v_u$, we get the Dirac mass matrix of neutrinos as

$$m_D = v_u \begin{pmatrix} \lambda_1 & 0 & 0 \\ 0 & 0 & \lambda_1 \\ 0 & \lambda_1 & 0 \end{pmatrix}. \hspace{1cm} (2.4)$$  

As for the Majorana mass matrix, the superpotential respecting gauge and flavor symmetries of our model are given by

$$W_R = m_R N N + \lambda_2 N N \Phi,$$  \hspace{1cm} (2.5)
where we have added the second term involving the flavon $\Phi$ to satisfy the TBM texture and to generate appropriate masses for the neutrinos. This term—which is at the renormaliziable level—will contribute to all the entries in the Majorana mass matrix. By using the multiplication rules of $A_4$, the superpotential $W_R$ develops into

$$W_R = m_R (N_1 N_1 + N_2 N_2 + N_3 N_3) + \frac{\lambda_2}{3} (2N_1 N_2 - N_2 N_3 - N_3 N_1) \Phi_1 + \frac{\lambda_3}{3} (2N_3 N_3 - N_1 N_2 - N_2 N_1) \Phi_3 + \frac{\lambda_3}{3} (2N_2 N_2 - N_1 N_3 - N_3 N_1) \Phi_2$$

(2.6)

and by taking the VEV of the flavons $\Phi$ as $\langle \Phi_1 \rangle = \langle \Phi_2 \rangle = \langle \Phi_3 \rangle = \nu_\Phi$, we find the Majorana neutrino mass matrix $M_R$ given by

$$M_R = m_R \begin{pmatrix} 1 + 2\alpha & -\alpha & -\alpha \\ -\alpha & 2\alpha & 1 - \alpha \\ -\alpha & 1 - \alpha & 2\alpha \end{pmatrix} \text{ with } \alpha = \frac{\lambda_2 \nu_\Phi}{3m_R}$$

(2.7)

The light neutrino mass matrix is obtained using Type I seesaw mechanism formula $m^I_{\nu} = -m_D M^{-1}_R m_D^T$ with the Dirac mass matrix as in Eq. (2.4), and we find

$$m^I_{\nu} = -m_0 \begin{pmatrix} a & b & b \\ b & c & a + b - c \\ b & a + b - c & c \end{pmatrix},$$

(2.8)

where we have adopted the following parametrization

$$a = \frac{\alpha + 1}{3\alpha + 1}, \quad b = \frac{\alpha}{3\alpha + 1}, \quad c = \frac{3\alpha^2 + 2\alpha}{9\alpha^2 - 1}, \quad m_0 = \frac{\lambda_2^2 \nu^2_\Phi}{m_R^2}$$

(2.9)

Moreover, the values of the parameters $a$ and $b$ are related as $a = 1 - 2b$; this property will be used in our numerical study. The matrix $m^I_{\nu}$ respects the well-known $\mu - \tau$ reflection symmetry [31], and the condition among the elements $(m^I_{\nu})_{11} + (m^I_{\nu})_{12} = (m^I_{\nu})_{22} + (m^I_{\nu})_{23}$ required to diagonalize $m^I_{\nu}$ by the TBM matrix as $m^I_{\nu} = U^T_{TBM} m_\nu U_{TBM} = \text{diag}(m_1, m_2, m_3)$ where the $U_{TBM}$ is given by

$$U_{TBM} = \begin{pmatrix} -\sqrt{2}/3 & 1/\sqrt{3} & 0 \\ -1/\sqrt{6} & 1/\sqrt{3} & -1/\sqrt{2} \\ 1/\sqrt{6} & 1/\sqrt{3} & 1/\sqrt{2} \end{pmatrix}.$$ 

(2.10)

2.2.2. Deviation using Type II seesaw mechanism

Now we turn to study the deviation from TBM, which consists of inducing a small perturbation in the neutrino mass matrix. This deviation is motivated by the fact that the
current experimental data on solar and atmospheric mixing angles are inadequate with the TBM values. The current $3\sigma$ ranges of the three mixing angles obtained from the global analysis in Ref. [9] are given by

$$0.271 \leq \sin^2 \theta_{12} \leq 0.345,$$

$$0.385(0.393) \leq \sin^2 \theta_{23} \leq 0.635(0.640),$$

$$0.01934(0.01953) \leq \sin^2 \theta_{13} \leq 0.02393(0.02408)$$

(2.11)

for a normal (inverted) mass hierarchy. As mentioned above, the perturbation is carried out through Type II seesaw, which implies the introduction of a scalar $SU(2)_L$ triplet $\Delta_d$ belonging to the 15-dimensional representation $H_{15}$ of the $SU(5)$ gauge group. The $SU(5) \times A_4$-invariant superpotential induces the Yukawa coupling involving $\Delta_d$ as

$$W^{II} = \lambda_3 \delta m_\nu \delta m_{15 \Delta_d} = \lambda_3 F F H_{15}.$$  

(2.12)

Using the VEV $\langle \Delta_d \rangle = v_{\Delta_d}$ of the $SU(2)_L$ triplet component of $H_{15} \equiv 15_{\Delta_d}$, the Majorana neutrino mass matrix reads as follows:

$$M^{II}_\nu = m_0 \begin{pmatrix} 0 & 0 & \varepsilon \\ 0 & \varepsilon & 0 \\ \varepsilon & 0 & 0 \end{pmatrix}$$  

with  

$$\varepsilon = \lambda_3 \frac{v_{\Delta_d}}{m_0},$$

(2.13)

where we factored this matrix by $m_0$ to form a dimensionless deviation parameter $\varepsilon$ as well as to ease the hybridization between the seesaw mechanisms. Even though the tiny mass of neutrinos is encoded in the VEV of the Higgs triplet—which is expressed as the ratio of the Higgs doublets VEVs and the Higgs triplet mass [11]—in ordinary seesaw Type II models, in the present paper we will discuss its contribution only through the deviation parameter $\varepsilon$ as we will see later when we perform a numerical study concerning the oscillation parameters. In addition, it is well known that the phenomenological constraint from the $\rho$ parameter that measures the ratio between the neutral and charged currents [32] restricts the VEVs of the Higgs multiplets higher than dimension two [33]. As in our model the calculation of the $\rho$ parameter requires taking into consideration at least three kinds of Higgs superfields—namely an $SU(2)$ triplet that belongs to $15_{\Delta_d}$ with hypercharge $Y = 2$, an $SU(2)$ triplet that belongs to $\overline{15}_{\Delta_u}$ with $Y = -2$, and an $SU(2)$ triplet that belongs to $24_H$ with $Y = 0$—we leave detailed investigations to future work.

Now, we turn to the total neutrino mass matrix generated by the hybrid seesaw mechanism that consists of combining the contribution of Type II seesaw in Eq. (2.13) and the
one arisen from the Type I seesaw in Eq. (2.8) as \( m_\nu = m^I_\nu + M^{II}_\nu \) with

\[
m_\nu = m_0 \begin{pmatrix}
-a & -b & \varepsilon - b \\
-b & \varepsilon - c & c - b - a \\
\varepsilon - b & c - b - a & -c
\end{pmatrix},
\]

(2.14)

where \( a, b, \) and \( c \) are as given in Eq. (2.9). The neutrino mass matrix is diagonalized by a transformation such as \( m_\nu^{\text{diag}} = \tilde{U}^T m_\nu \tilde{U} \) where the system of eigenvectors and eigenvalues can be developed as power series of \( \varepsilon \); we find up to order \( O(\varepsilon^2) \), the matrix \( \tilde{U} \) given in terms of its eigenvectors as

\[
\tilde{U} = \begin{pmatrix}
\frac{1}{\sqrt{6}} - \frac{\sqrt{2}}{3\varepsilon} & \frac{1}{\sqrt{3}} - \frac{\varepsilon}{2\sqrt{2}(a-c)} \\
\frac{1}{\sqrt{6}} + \frac{\sqrt{2}}{3\varepsilon} & \frac{1}{\sqrt{3}} - \frac{\varepsilon}{4\sqrt{2}(a-c)} \\
\frac{1}{\sqrt{6}} & \frac{1}{\sqrt{2}} + \frac{\varepsilon}{4\sqrt{2}(a-c)}
\end{pmatrix} + O(\varepsilon^2)
\]

(2.15)

and eigenvalues

\[
m_1 = m_0 \left( b - a - \frac{\varepsilon}{2} \right), \quad m_2 = -m_0 \left( a + 2b - \varepsilon \right), \quad m_3 = m_0 \left( b + a - 2c + \frac{\varepsilon}{2} \right)
\]

(2.16)

Consequently, the mixing angles \( \theta_{13} \) and \( \theta_{23} \) become

\[
\sin \theta_{13} = \left| \frac{\varepsilon}{2\sqrt{2}(a-c)} \right|, \quad \sin \theta_{23} = \left| \frac{\varepsilon}{4\sqrt{2}(a-c)} + \frac{1}{\sqrt{2}} \right|
\]

(2.17)

while the solar angle maintains its TBM (maximal) value \( \sin \theta_{12} = 1/\sqrt{3} \). We have now a nonvanishing reactor angle \( \theta_{13} \) and a small shift from the TBM value for the atmospheric angle \( \theta_{23} \).

### 2.3. Mass-squared differences and mixing angles

Concerning neutrino masses, the current neutrino oscillation experiments are only sensitive to mass-squared differences where we distinguish between two mass hierarchies: normal mass hierarchy (NH) where \( m_1 < m_2 < m_3 \) and inverted mass hierarchy (IH) where \( m_3 < m_1 < m_2 \). Their 3\( \sigma \) experimental ranges are given by

\[
0.0000703 \leq \Delta m^2_{21} \leq 0.0000809, \\
(0.002399)0.002407 \leq |\Delta m^2_{31}| \leq 0.002643(0.002635)
\]

(2.18)
with $l = 1$ ($l = 2$) for NH (IH). In our proposal, by using the masses in Eq. (2.16), the solar $\Delta m_{21}^2$ and atmospheric $\Delta m_{31}^2$ mass-squared differences up to first order in $\varepsilon$ are expressed as

$$
\begin{align*}
\Delta m_{21}^2 &= 3m_0^2 \left( b^2 - be + 2ab - a\varepsilon \right), \\
\Delta m_{31}^2 &= 2m_0^2 \left( b - c \right) \left( 2a - 2c + \varepsilon \right), \\
\Delta m_{32}^2 &= m_0^2 \left( 3a\varepsilon - 2ab - 2c\varepsilon - 3b^2 + 5b\varepsilon - 4c \left( a + b - c \right) \right).
\end{align*}
$$

(2.19)

By using the mixing angles in Eq. (2.17), we show in the left panel (right panel) of Fig. 1 the correlation among the parameters $\sin \theta_{23}$, $\varepsilon$, and $\sin \theta_{13}$ for the NH case (IH case). The experimental inputs of the mass squared differences $\Delta m_{31}^2(\Delta m_{32}^2)$ as well as their expressions given in Eq. (2.19) are taken into account. Before we discuss the ranges of the oscillation parameters, we should notice that the recent measurement of the atmospheric angle from the NOvA experiment disfavored the maximal value $\theta_{23} = 45^\circ$ [12], while experiments like T2K [5] and IceCube [34] still prefer maximal mixing. In the case of nonmaximal mixing, there are two different octants of $\theta_{23}$: the lower octant (LO) with $\theta_{23} < 45^\circ$ and the higher octant (HO) with $\theta_{23} > 45^\circ$. The NOvA experiment provided two degenerate ranges for the normal mass hierarchy [12]: $\sin^2 \theta_{23} = 0.404^{+0.030}_{-0.022}$ (LO) and $\sin^2 \theta_{23} = 0.624^{+0.022}_{-0.030}$ (HO).

Back to Fig. 1, we observe that while the entire $3\sigma$ range of $\sin \theta_{13}$ is allowed, the ranges of the atmospheric angle become more restrained. In the left panel (normal hierarchy), we observe that both octants of the atmospheric angle are allowed and we have

$$
0.629 \lesssim \sin \theta_{23}(\text{LO}) \lesssim 0.637, \quad 0.776 \lesssim \sin \theta_{23}(\text{HO}) \lesssim 0.784.
$$

(2.20)
These intervals correspond to
\[ 0.03 \lesssim \varepsilon(\text{LO}) \leq 0.1, \quad 0.01 \lesssim \varepsilon(\text{HO}) \leq 0.1. \tag{2.21} \]

In the right panel (inverted hierarchy), we have for both octants of the atmospheric angle
\[ 0.629 \lesssim \sin \theta_{23}(\text{LO}) \lesssim 0.637, \quad 0.777 \lesssim \sin \theta_{23}(\text{HO}) \lesssim 0.784, \tag{2.22} \]
which correspond to the following intervals of the deviation parameter:
\[ 0.015 \lesssim \varepsilon(\text{LO}) \leq 0.1, \quad 0.013 \lesssim \varepsilon(\text{HO}) \leq 0.1. \tag{2.23} \]

In our proposal, it is clear that the maximal atmospheric angle, which corresponds to \( \sin \theta_{23} \simeq 0.7 \) in both panels of Fig. 1 is excluded. In fact, this is due to the contribution of the Higgs triplet \( \Delta_d \in 15_{\Delta_d} \) (encoded in the parameter \( \varepsilon \)) which led to the Majorana mass matrix \( [2.13] \) via Type II seesaw mechanism, allowing us to explain the nonzero reactor angle \( \theta_{13} \neq 0 \) as well as providing a deviation of the atmospheric angle from its maximal value. All the allowed regions predicted in our model for \( \sin \theta_{23} \) in the case of normal hierarchy are within the ranges of LO and HO provided by the NOvA experiment. To plot the above figures, we have taken \( |a| \lesssim 1 \) and \( |b| \lesssim 1 \) which is clear from Eq. \( [2.9] \) while the parameter \( c \) is allowed to vary freely. Moreover, as the parameter of deviation \( \varepsilon \) has to be small, we have taken its range to be around \( \mathcal{O}(1/10) \). We have also fixed \( m_0 \) in the range \( [0, \frac{1}{10}] \) since it is well known that the mass of the right-handed neutrinos—proportional to \( m_R \)—lies at a scale beyond the reach of present experiments, and it is usually taken at the GUT scale in grand unified theories.

As a follow-up to the above discussion, it is clear that the intervals of the parameters \( a, b, \) and \( c \)—expressed as a function of \( \alpha = (\lambda_2 v_\Phi/3m_R) \)—are fixed according to Eq. \( [2.9] \). However, in order to find their restricted ranges compatible with the oscillation experiments, we plot in Fig. 2 the correlation among them by using the 3\( \sigma \) experimental values of the mixing angles and the mass-squared differences as well as Eqs. \( [2.17] \) and \( [2.19] \). Hence, we observe that for both mass hierarchies, the allowed ranges for the parameter \( b \) is around \( [0, 0.9997] \), while the parameters \( a \) and \( c \) vary in the ranges \( [-1, 1] \) and \( [-1.47, 1.43] \), respectively. These new ranges will be used as inputs to perform a numerical study concerning the phenomenology of neutrino in the next section.

### 3. PHENOMENOLOGICAL IMPLICATIONS

In this section, by using the model parameters that are restricted by the 3\( \sigma \) experimental values of the mixing angles and the mass-squared differences, we show by means of scatter
plots for both hierarchies the physical observables $m_{ee}$ and $m_\beta$ related respectively to neutrinoless double beta decay and tritium beta decay experiments, and we also provide scatter plot predictions on the sum of neutrino masses as well as on the Dirac $CP$ violating phase.

### 3.1. Neutrinoless double beta decay

One of the most known neutrino mass related experiments is the neutrinoless double beta decay ($0\nu\beta\beta$) process, which has not been observed yet. Its discovery would prove that neutrinos are Majorana particles, and it would also prove that the lepton number $L$ is violated. The decay amplitude for the $0\nu\beta\beta$ process is proportional to the effective Majorana neutrino mass given by

$$|m_{ee}| = \left| \sum_{i=1}^{3} U_{ei}^2 m_i \right|,$$

where $m_i$ are the three neutrino masses and $U_{ei}$ are the elements of the first row of the PMNS matrix [36]. In our proposal, this mixing matrix is given by

$$\tilde{U}_d = \tilde{U} \cdot \text{diag}(1, e^{i\alpha}, e^{i\beta}),$$

where $\alpha$ and $\beta$ are the Majorana $CP$ violating phases and $\tilde{U}$ is given in Eq. (2.15). Currently, the most recent bounds of $m_{ee}$ come from the KamLAND-Zen [37] and GERDA [38] experiments; they are respectively given by

$$|m_{ee}| < 0.061 - 0.165 \text{ eV}, \quad |m_{ee}| < 0.15 - 0.33 \text{ eV}.$$
To study the variation the effective Majorana mass $m_{ee}$ with the lightest neutrino mass in our model for both hierarchies, we replace $U_{ei}$ in Eq. (3.1) by the elements of the first row of $\tilde{U}_d$; the effective Majorana mass takes the form

$$|m_{ee}| = \left| \frac{2m_1}{3} + \frac{m_2}{3} e^{2i\alpha} + \frac{m_3}{8} \frac{e^2}{(a-c)^2} e^{2i\beta} \right|.$$  \hspace{1cm} (3.4)

Furthermore, for the NH case where $m_1$ is the lightest neutrino mass, we substitute $m_2$ by $\sqrt{\Delta m_{21}^2 + m_1^2}$ and $m_3$ by $\sqrt{\Delta m_{31}^2 + m_1^2}$, and for the IH case where $m_3$ is the lightest neutrino mass, we substitute $m_2$ by $\sqrt{m_3^2 - \Delta m_{32}^2}$ and $m_1$ by $\sqrt{m_3^2 - \Delta m_{32}^2 - \Delta m_{21}^2}$. The explicit forms of $m_i$ and $\Delta m_{ij}^2$ as a function of parameter space of the model are as shown in Eqs. (2.16) and (2.19). By using the above definitions and the limits from experiments—see Eq. (3.3)—we plot in Fig. 3 $m_{ee}$ as a function of the lightest neutrino mass for both mass hierarchies where the Majorana phases $\alpha$ and $\beta$ are allowed to vary in the range $[0 - 2\pi]$; we find that the $3\sigma$ allowed regions for the effective Majorana mass are $m_{ee} (\text{eV}) \in [0.00017, 0.06084]$, which corresponds to $m_1 (\text{eV}) \in [0.00012, 0.08267]$ for the normal hierarchy, and $m_{ee} (\text{eV}) \in [0.02286, 0.05878]$, which corresponds to $m_3 (\text{eV}) \in [0.00144, 0.05879]$ for the inverted hierarchy. For both hierarchies, the obtained regions of $m_{ee}$ are within the current experimental data and may be reached in future neutrinoless double-beta decay experiments \cite{39}. In particular, the obtained ranges can be tested in future experiments like KamLAND-Zen, which plans to reach a sensitivity below 50 meV on $|m_{ee}|$, and thus, it will start to constrain the inverted mass hierarchy region \cite{40}.

---

FIG. 3: Left: The effective Majorana mass as a function of the lightest neutrino mass for NH. Right: Same as in the left panel but for IH. The horizontal gray band in both panels indicates an upper limit on the sum of the three light neutrino masses from Planck Collaboration.
3.2. Tritium beta decay

The tritium beta decay is the most sensitive direct way to measure the absolute neutrino mass scale ignoring the nature of neutrinos \[41\]. The limit (at 95\% C.L.) from the Troitsk and Mainz experiments of the effective electron neutrino mass are, respectively, given by \( m_\beta < 2.12 \text{ eV} \) and \( m_\beta < 2.3 \text{ eV} \) \[42, 43\], while the current generation of neutrino mass measurement comes from the KATRIN experiment with a sensitivity of \( m_\beta < 0.2 \text{ eV} \) (at 90 \% C.L.) \[44\]. The quantity \( m_\beta \) (or \( m_{\nu_e} \)) is defined in terms of the mass eigenvalues \( m_i \) and mixing matrix elements \( U_{ei} \): \( m_\beta^2 = \sum_{i=1}^{3} U_{ei}^2 \cdot m_i^2 \). In terms of our model parameters, it is expressed as

\[
m_\beta = \left( \frac{2m_1^2}{3} + \frac{m_2^2}{3} + \frac{m_3^2}{8} \frac{\varepsilon^2}{(a - c)^2} \right)^{\frac{1}{2}}.
\]

(3.5)

Similar to the discussion of the effective Majorana neutrino mass, in the NH (IH) case, we

use the same definitions for \( m_2 \) and \( m_3 \) (\( m_1 \) and \( m_2 \)). Then, we plot in Fig. 4 the effective electron neutrino mass \( m_\beta \) as a function of the lightest neutrino mass \( m_i \). The cyan region (green region) is obtained by varying all the input parameters in their 3\( \sigma \) ranges for NH (IH) while our model values are presented by the orange points (the red points). Hence, we find that the effective electron neutrino mass lies in the range \( 0.0214 \lesssim m_\beta(\text{eV}) \lesssim 0.0298 \) for NH and \( 0.0488 \lesssim m_\beta(\text{eV}) \lesssim 0.0882 \) for IH, while their corresponding lightest neutrino masses are constrained in the range \( 0.0206 \lesssim m_1(\text{eV}) \lesssim 0.0291 \) for NH and \( 0.0058 \lesssim m_3(\text{eV}) \lesssim 0.0729 \) for IH. The extracted ranges of \( m_\beta \) are compatible with the above mentioned experiments for both mass hierarchies. However, the expected future sensitivity from Project 8 \[45\] is as low as 0.04 eV, which means that only the range corresponding to NH is allowed.

FIG. 4: \( m_\beta \) as a function of the lightest neutrino mass \( m_i \) for both mass hierarchies.
3.3. Sum of neutrino masses

Although the absolute mass scale of the neutrinos remains unknown, the sum of the three light neutrino masses $\sum_{i=1}^{3} |m_i|$ is constrained by a cosmological upper bound given by the Planck Collaboration’s limit $\sum_{i=1}^{3} |m_i| < 0.17$ eV \[46\]. In our model, the sum of neutrino masses is expressed in terms of the model parameters as

$$m_\Sigma = \sum_{i=1}^{3} |m_i| = m_0 (\varepsilon - 2c - a).$$  \hspace{1cm} (3.6)

Using the $3\sigma$ ranges of mass-squared differences \[2.18\] and mixing angles \[2.11\], we show in

![Graph showing the sum of neutrino masses as a function of the lightest neutrino mass $m_i$, present in both cases NH and IH, and the horizontal and vertical bands in gray correspond to the bounds excluded by cosmology.]

**FIG. 5:** Sum of neutrino masses as a function of the lightest neutrino mass $m_i$, present in both cases NH and IH, and the horizontal and vertical bands in gray correspond to the bounds excluded by cosmology.

Fig. 5 the dependence of the sum of the light neutrino masses as a function of the lightest neutrino mass for both mass hierarchies. The green region (cyan region) is obtained by varying all the input parameters in their $3\sigma$ ranges for normal hierarchy (inverted hierarchy) while our model values are presented by the orange points (the red points). Hence we find that the sum of the light neutrino masses lies in the range $0.0702 \lesssim m_\Sigma \text{(eV)} \lesssim 0.1670$ for NH and $0.1064 \lesssim m_\Sigma \text{(eV)} \lesssim 0.1698$ for IH, while their corresponding lightest neutrino masses are constrained in the range $0.0081 \lesssim m_1 \text{(eV)} \lesssim 0.0480$ for NH and $0.0078 \lesssim m_3 \text{(eV)} \lesssim 0.0406$ for IH. Thus, for both mass hierarchies, the sum of neutrino masses gets more restricted as compared to the Planck limit, and these ranges may be tested in future cosmological observations.
3.4. Dirac CP violation

The Dirac CPV phase $\delta_{CP}$ is one among the unknown quantities in the physics of neutrino, and its measurement becomes more important when recent experiments reported the nonzero value of the reactor angle $\theta_{13}$ as they are related in the PMNS matrix. Moreover, estimations on the CPV phase $\delta_{CP}$ can be obtained by considering the Jarlskog invariant quantity $J_{CP}$ which is defined as $J_{CP} = \text{Im}\{U_{\mu 3}U_{e3}^*U_{e3}U_{\mu 3}^*\}$ and by using the PMNS matrix. It is expressed as

$$J_{CP} = \cos \theta_{12} \sin \theta_{12} \cos \theta_{23} \sin \theta_{23} \cos \theta_{13}^2 \sin \theta_{13} \sin \delta_{CP},$$

(3.7)

where the allowed ranges at 3σ of $\sin \theta_{12}$, $\sin \theta_{23}$, and $\sin \theta_{13}$ are given in Eq. (2.11) while the allowed 3σ ranges of CPV phase $\delta_{CP}$ are giving by [9]

$$0 \leq \delta_{CP} \leq 2\pi \text{ for NH }, \quad 0.8\pi \leq \delta_{CP} \leq 2.17\pi \text{ for IH.}$$

(3.8)

We show in Fig. 6 the behavior of $J_{CP}$ as a function of $\delta_{CP}$ with $\sin \theta_{23}$ presented in the

![Palettes for NH (left panel) and IH (right panel). The ranges of $J_{CP}$ and their corresponding Dirac CPV $\delta_{CP}$ as well as the ranges of $\sin \theta_{23}$ for both HO and LO are as shown in Table II. Therefore, the left panel shows that for the values around $\delta_{CP} = 0.5\pi$ and $\delta_{CP} = 1.5\pi$, the $CP$ is maximally violated when the magnitude of $J_{CP}$ is maximal ($J_{CP} \approx -0.034$ and $J_{CP} \approx 0.034$) while in the right panel it is maximally violated ($J_{CP} \approx -0.034$ and $J_{CP} \approx 0.019$) around the values $\delta_{CP} = 0.8\pi$ and $\delta_{CP} = 1.5\pi$.]

FIG. 6: Left: Scatter plot of $\sin \theta_{23}$ in the ($J_{CP}, \delta_{CP}$) plane for normal hierarchy. Right: Same as in left panel for IH.
| JCP       | δCP       | sinθ_{23}  | Color regions          |
|-----------|-----------|------------|------------------------|
| NH(HO)    | [−0.034, 0.034] | [0, 1.91π] | [0.776, 0.784] | Blue and dark blue |
| NH(LO)    | [−0.034, 0.034] | [0, 1.93π] | [0.629, 0.637] | Dark orange         |
| IH(HO)    | [−0.034, 0.019] | [0.8π − 2.08π] | [0.779, 0.784] | Blue and dark blue |
| IH(LO)    | [−0.034, 0.019] | [0.8π − 2.14π] | [0.629, 0.637] | Dark orange       |

TABLE II: Allowed ranges of J_{CP} for both mass hierarchies and both octants and their corresponding δ_{CP} and sinθ_{23} ranges extracted from Fig. 6.

4. CONCLUSION

In this work, we have constructed a renormalizable hybrid seesaw neutrino model in the framework of SUSY SU(5) GUT extended by a discrete A_4 family symmetry. The dominant TBM pattern is obtained from Type I seesaw mechanism while Type II seesaw is responsible for a small deviation from TBM. Both seesaws are controlled by the action of the A_4 flavor symmetry through its algebraic properties. We found that the predictions of our proposal concerning the mixing angles and masses are consistent with the recent measurements. In particular, we showed that the deviation by Type II seesaw leads to a nonmaximal atmospheric angle θ_{23} as reported recently by the NOvA experiment and a nonvanishing reactor angle θ_{13}. Thus, we made a full analysis depending on the octant of θ_{23}.

We also studied the phenomenological consequences of our proposal where we showed through scatter plots the allowed ranges for the physical observables and model parameters which we have restricted by using the 3σ ranges of the neutrino oscillation parameters for both mass hierarchies. We found also that the sum of neutrino masses and CPV phase are within the allowed experimental regions. Furthermore, we found that the ranges of the physical observables involving the effective Majorana neutrino mass m_{ββ} and the electron neutrino mass m_{β} are preferred in the case of normal mass hierarchy. For the latter, the obtained range of m_{β} in the inverted mass hierarchy case is forbidden by future sensitivity from Project 8.
APPENDIX A: CHARGED FERMION SECTORS AND PROTON DECAY

In this appendix, we provide a brief study of the charged lepton sector to show the possibility to use an $A_4$ assignment for the remaining $SU(5)$ superfield content that does not affect the neutrino mixing. However, it is well known in GUTs that because the quarks and leptons are unified in the same group representations, the charged lepton and the down quark masses are derived from the same superpotential. Thus we also provide in this appendix a concise discussion of the quark sector fixing up the unwanted mass relations between down quarks and charged leptons

$$m_e = m_d , \quad m_\mu = m_s , \quad m_\tau = m_b.$$  \hspace{1cm} (A.1)

We begin by assigning the quantum numbers to the rest of the chiral superfields of our $SU(5) \times A_4$ proposal. Thus, in addition to the superfields relevant for the neutrino sector—see Table I—the matter $10^i_m = (U^c_i, E^c_i, Q_i)$ of the three generations $i = 1, 2, 3$ live in the $A_4$ representations $1_{(1,\omega)}$, $1_{(1,\omega^2)}$, and $1_{(1,1)}$, respectively. As discussed in the neutrino sector above, one flavon superfield is necessary to accommodate the observed neutrino oscillation parameters. Similarly, to generate appropriate masses for the three generations of up quarks and down quarks (as well as charged leptons), two extra flavons are needed in the superpotential of up quarks $W_u$; these are denoted by $\chi$ and $\varphi$. On the other hand, three extra flavons are required in the superpotential of down quarks and charged leptons $W_{e,d}$; these are denoted as $\rho$, $\eta$, and $\sigma$. The $A_4$ irreducible representations of these new flavons are as given in Table III. Furthermore, in order to achieve the correct mass hierarchy and to get rid of the unwanted couplings, we add an additional global $U(1)$ symmetry where its charge assignments for all the superfields in our proposal are as given in the last rows of Tables III and IV. In fact, these $U(1)$ quantum numbers are identified by taking into account the

| Flavons | $\Phi$ | $\chi$ | $\varphi$ | $\rho$ | $\sigma$ | $\eta$ |
|---------|--------|--------|-----------|-------|---------|-------|
| SU(5)   | 1      | 1      | 1         | 1     | 1       | 1     |
| $A_4$   | $3_{-1,0}$ | $1_{(1,\omega)}$ | $1_{(1,\omega^2)}$ | $3_{-1,0}$ | $3_{-1,0}$ | $3_{-1,0}$ |
| U(1)    | 0      | -4     | 2         | 7     | 8       | 5     |

TABLE III: Flavon superfields needed in the quark and charged lepton sectors and their quantum numbers under $SU(5) \times A_4 \times U(1)$. 

preexisting $SU(5) \times A_4$ invariant Yukawa couplings in the neutrino sector. Indeed, the flavon $\Phi$ must carry a zero $U(1)$ charge in order to preserve both couplings given in the Majorana superpotential (2.5). However, since the nonrenormalizable terms up to order $\mathcal{O}(1/\Lambda^2)$ are needed in the charged fermion sectors as we will see below, this zero $U(1)$ charge for the flavon $\Phi$ enables its coupling with the operators $F_i F_i H_{15}$ and $N_i F_i H_5$ via the following higher dimensional operators:

$$F_i F_i H_{15} \left( \frac{\Phi}{\Lambda} \right), \quad N_i F_i H_5 \left( \frac{\Phi}{\Lambda} \right). \quad (A.2)$$

These couplings which destroy the form of neutrino mass matrix (2.14) that led to the desired oscillation parameters must be suppressed. This is possible if we assume that $\nu_\Phi \ll \Lambda$, which is acceptable according to Eqs. (2.7) and (2.9). On the other hand, even if the VEV of the flavon $\Phi$ is around the cutoff scale—say $\Phi \simeq \Lambda$—this would just give terms that are relative to the leading ones: $F_i F_i H_{15}$ and $N_i F_i H_5$. Moreover, it is well known that the $SU(5)$ GUT predicts the mass relations in Eq. (A.1), which are not acceptable for the first and second generations due to their disagreement with the experimental data [35]. Nevertheless, the well known Georgi-Jarlskog (GJ) mechanism [48] overcomes this issue by introducing an additional Higgs in the 45-dimensional $SU(5)$ representation leading to the mass relations

$$3m_e = m_d, \quad m_\mu = 3m_s, \quad m_\tau = m_b. \quad (A.3)$$

In our proposal, this 45 Higgs denoted as $H_{45}$ is placed in an $A_4$ triplet$^1$—$\tilde{H}_{45} = (H_{45}, 0, 0)^T$—while its charge under the additional $U(1)$ symmetry is $q_{U(1)} = -5$. Recall that this Higgs

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline
Fields & $F_i$ & $N_i$ & $H_5$ & $H_5$ & $H_{15}$ & $T_1$ & $T_2$ & $T_3$ & $H_{15}$ \\
\hline
SU(5) & $\tilde{5}_m$ & $1^i$ & $5_{H_u}$ & $5_{H_d}$ & $15_{\Delta_d}$ & $10^1_m$ & $10^2_m$ & $10^3_m$ & $\tilde{15}_H$ \\
\hline
$A_4$ & $3_{-1,0}$ & $3_{-1,0}$ & $1_{(1,1)}$ & $1_{(1,\omega)}$ & $1_{(1,\omega)}$ & $1_{(1,\omega^2)}$ & $1_{(1,1)}$ & $3_{-1,0}$ & \\
\hline
U(1) & $-2$ & 0 & 2 & $-4$ & 4 & 1 & $-2$ & $-1$ & 4 \\
\hline
\end{tabular}
\caption{Matter and Higgs content of the model and their quantum numbers under $SU(5) \times A_4 \times U(1)$.}
\end{table}

\footnote{Notice that the choice of putting the 45-dimensional Higgs $H_{45}$ in an $A_4$ triplet is to ensure the invariance of its coupling with $T_2 F_i$ without having to add other flavon triplets.}
$H_{55}$ is antisymmetric in $SU(5)$ indices and satisfies the following relations [48]:

\[
(H_{55})_{ab}^{cd} = -(H_{55})_{bc}^{da}, \quad (H_{55})_{a}^{ab} = 0,
\]

\[
\langle (H_{55})_{i}^{45} \rangle = v_{45}, \quad i = 1, 2, 3, \quad \langle (H_{55})_{4}^{45} \rangle = -3v_{45}.
\]  

(A.4)

With the $A_4 \times U(1)$ charge assignments shown in Table IV, the usual renormalizable Yukawa couplings $Y_1 T_1 F_i H_5$, $Y_2 T_2 F_i H_5$, and $Y_3 T_3 F_i H_5$ are not invariant under $A_4$ flavor symmetry and they are carrying the $U(1)$ charges $-5$, $-8$, and $-7$, respectively. Thus, to restore the invariance under the $A_4 \times U(1)$ symmetry, each one of these couplings requires a different $A_4$ triplet flavon superfield, namely $\eta$, $\sigma$, and $\rho$ with $U(1)$ charges 5, 8, and 7, respectively. Therefore, the $A_4 \times U(1)$ invariant superpotential of the down quarks and charged leptons involving the three flavons $\eta$, $\sigma$, and $\rho$ as well as well the Higgs $H_{55}$ is given by

\[
W_{d,e} = \frac{Y_1}{\Lambda} T_1 (F_i \eta) H_5 + \frac{Y_2}{\Lambda} T_2 (F_i \sigma) H_5 + \frac{Y_3}{\Lambda} T_3 (F_i \rho) H_5 + Y_{45} T_2 F_i \tilde{H}_{55},
\]  

(A.5)

where $Y_1$, $Y_2$, $Y_3$, and $Y_{45}$ are the Yukawa mass matrices and $\Lambda$ represents the cutoff scale of the model. Notice that the coupling $T_2 F_i \tilde{H}_{45} (\frac{\rho}{\Lambda})$ is also allowed by the symmetries of the model, but again its suppression is guaranteed by the condition $v_\Phi \ll \Lambda$. Using $A_4$ tensor products, the superpotential $W_{d,e}$ develops into

\[
W_{d,e} = \frac{Y_1}{\Lambda} T_1 F_2 \eta H_5 + \frac{Y_2}{\Lambda} T_2 F_1 \sigma H_5 + \frac{Y_3}{\Lambda} T_3 (F_3 \rho) H_5 + Y_{45} T_2 F_2 H_{55},
\]  

(A.6)

The masses arise from the breaking of $A_4 \times U(1)$ family symmetry as well as the breaking of the electroweak symmetry. Therefore, by taking the flavon triplet VEVs along the directions

\[
\langle \sigma \rangle = v_\sigma (1, 0, 0)^T, \quad \langle \rho \rangle = v_\rho (1, 0, 0)^T, \quad \langle \eta \rangle = v_\eta (1, 0, 0)^T,
\]  

(A.7)

the Higgs doublet $H_d$ responsible for the electroweak symmetry breaking as usual $\langle H_d \rangle = v_d$, and the Higgs 45 as in Eq. (A.4), we obtain the mass matrices for down-type quarks $M_d$ and charged leptons $M_e$

\[
M_d = \begin{pmatrix} 0 & Y_1 r & 0 \\ Y_2 h & Y_{45} v_{45} & 0 \\ 0 & 0 & Y_3 t \end{pmatrix}, \quad M_e = \begin{pmatrix} 0 & Y_2 h & 0 \\ Y_1 r & -3Y_{45} v_{45} & 0 \\ 0 & 0 & Y_3 t \end{pmatrix},
\]  

(A.8)

where $r = v_d v_\sigma / \Lambda$, $h = v_d v_\rho / \Lambda$, and $t = v_d v_\rho / \Lambda$. By assuming $Y_{45} v_{45} \gg Y_1 r \approx Y_2 h$, we diagonalize the mass matrices $M_d$ and $M_e$ where we find that the masses of down-type
quarks and charged leptons are respectively given by

\[
m_d = \frac{Y_d^2 r^2}{Y_{45} v_{45}}, \quad m_s = \frac{Y_s^2 r^2}{Y_{45} v_{45}} + \frac{Y_d^2 r^2}{3 Y_{45} v_{45}}, \quad m_\tau = |Y_\tau t|, \quad m_m = \frac{Y_m^2 r^2}{Y_{45} v_{45}}, \quad m_\mu = \frac{Y_\mu^2 r^2}{Y_{45} v_{45}} + \frac{Y_d^2 r^2}{3 Y_{45} v_{45}}, \quad m_b = |Y_b t|, \quad (A.9)
\]

where these masses imply the Georgi-Jarlskog relations given in Eq. (A.3). Notice that these mass relations are admissible at the GUT scale at leading order and can be improved assuming the SUSY threshold corrections and appropriate values of \( \tan \beta = \frac{v_u}{v_d} \); for more details on the SUSY threshold corrections procedure see Refs. [49, 50]. On the other hand, an alternative way to go beyond the \( b-\tau \) unification in GJ predictions at high scale is through higher dimensional effective operators [49, 51]. These operators involve additional Higgses in \( 24_H \) or \( 75_H \) and a nontrivial \( SU(5) \) messenger fields \( X \) and \( \overline{X} \) allowing for relations such as \( m_\tau = \frac{3}{2} m_b \). All possible relations between down-quark and the charged lepton masses are listed in Table 1 of Ref. [49] and Table 2 of Ref. [51]. One of these GUT scale relations using fermion and scalar messenger fields is studied in the framework of \( SU(5) \times A_4 \) in Ref. [52].

Regarding the up-type quark sector, besides the top quark mass which is preferred to arise from a renormalizable coupling, the remaining up and charm quark masses are derived from higher dimensional Yukawa couplings involving flavon superfields. Indeed, in our model, two different flavons \( \chi \) and \( \varphi \) couple to the first and second generations, respectively. Thus, the superpotential of the up-type quarks respecting gauge and flavor symmetries takes the form

\[
W_u = \frac{Y_u}{\Lambda} T_1 T_1 H_5 \chi + \frac{Y_c}{\Lambda} T_2 T_2 H_5 \varphi + Y_t T_3 T_3 H_5, \quad (A.10)
\]

where \( y_u, y_c \), and \( y_t \) are the Yukawa coupling constants for up-, charm-, and top-type quarks. As usual, the up-type quark masses arise from the breaking of the flavor and electroweak symmetries. Thus, when the flavons \( \varphi \) and \( \chi \) and the Higgs \( H_u \) develop their VEVs as

\[
\langle \varphi \rangle = v_\varphi, \quad \langle \chi \rangle = v_\chi, \quad \langle H_u \rangle = v_u, \quad (A.11)
\]

we obtain a diagonal mass matrix of the up-type quarks given by

\[
M_{up} = v_u \begin{pmatrix}
Y_u v_\chi / \Lambda & 0 & 0 \\
0 & Y_c v_\varphi / \Lambda & 0 \\
0 & 0 & Y_t
\end{pmatrix}, \quad (A.12)
\]

with the mass eigenvalues as

\[
m_u = Y_u v_\chi / v_u, \quad m_c = Y_c v_\varphi / v_u, \quad m_t = Y_t v_u. \quad (A.13)
\]
The large mass of the top quark is obtained at tree level, while the mass hierarchy among the first two generations of up-type quarks can be obtained by assuming a hierarchy between the VEVs of the flavons $\chi$ and $\varphi$.

As for the mixing in the quark sector, it is defined as $|U_Q| = |U^\dagger_{up} U_d|$ where $U_d$ is the matrix that diagonalizes the mass matrix of down quarks $M_d$ while $U_{up}$ is the one that diagonalizes the mass matrix of up quarks $M_{up}$. Since this latter is diagonal (A.12), $U_{up}$ is just the identity matrix, and thus, the total mixing matrix is the one that diagonalizes the mass matrix of the down quarks $M_d$ (A.8); we find

$$U_Q = U_d = \begin{pmatrix} \frac{-Y_{45}v_{45} - E}{2Y_1 r} & \frac{-Y_{45}v_{45} + E}{E Y_1 r} & 0 \\ \frac{2}{Y} & \frac{2}{Z} & 0 \\ 0 & 0 & 1 \end{pmatrix}$$  \hspace{1cm} (A.14)

with

$$F = \sqrt{Y_{45}^2 v_{45}^2 + 4Y_1^2 r^2}, \quad Z = \sqrt{4 + \left(\frac{Y_{45}v_{45} + F}{Y_1 r}\right)^2}, \quad E = \sqrt{4 + \left(\frac{Y_{45}v_{45} - F}{Y_1 r}\right)^2}. \hspace{1cm} (A.15)$$

Notice that the zero entries in the mixing matrix (A.14) can be seen to be a first approximation to the mixing matrix $V_{CKM}$ of the quark sector [35]. The nonzero values of this entries can be obtained by considering higher dimensional operators involving flavon superfields in the quark sector. As for the mixing in the charged lepton sector, the diagonalization of the mass matrix $M_e$ in Eq. (A.8) is given by

$$U_e \simeq \begin{pmatrix} \frac{3Y_{45}v_{45} - L}{G Y_1 r} & \frac{3Y_{45}v_{45} + L}{K Y_1 r} & 0 \\ \frac{2}{G} & \frac{2}{K} & 0 \\ 0 & 0 & 1 \end{pmatrix}$$  \hspace{1cm} (A.16)

with

$$L = \sqrt{9Y_{45}^2 v_{45}^2 + 4Y_1^2 r^2}, \quad G = \sqrt{4 + \left(-\frac{3Y_{45}v_{45} + L}{Y_1 r}\right)^2}, \quad K = \sqrt{4 + \left(\frac{3Y_{45}v_{45} + L}{Y_1 r}\right)^2}. \hspace{1cm} (A.17)$$

From this matrix, it is clear that the charged lepton mixing angles $\theta_{13}^l$ and $\theta_{23}^l$ are both equal to zero; thus in our model the mixing from the charged lepton sector does not affect the mixing angles of the neutrino sector given in Eq. (2.17). Notice by the way that the total mixing in the lepton sector $U_{PMNS} = U_e^\dagger \bar{U}$ is proportional to $\bar{U}$ with a small shift of the mixing angle $\theta_{12}^l$.

We end this appendix by giving comments concerning the well-known four- and five-dimensional operators that contribute to fast proton decay in supersymmetric $SU(5)$ GUT...
models. In this respect, the dangerous proton decay terms arise from the dimension four \( \lambda^{ijk}10^i_m\bar{5}_m^i\bar{5}_m^j \) and dimension five \( \lambda^{ijkl}10^i_m10^j_m\bar{5}_m^k \) operators. These operators are dangerous in the sense that they lead to proton decay rates far larger than the experimental limits. As regards to the former operators, they contribute to the proton decay through the term violating baryon number \((U^c_1D^c_1D^c_1)\) combined with the term \((Q_iL^c_jD^c_k)\) that violates the lepton number with family indices as \(i, j = 1, 2\) and \(k = 2, 3\). In fact, these operators which are renormalizable can be avoided by imposing the usual \(R\) parity as in the case of the MSSM \[53\]. However, in our \(SU(5) \times A_4 \times U(1)\) proposal, these four-dimensional operators that are given by

\[
10^i_m\bar{5}_m^i\bar{5}_m^j \rightarrow T_1F_jF_j + T_2F_jF_j + T_3F_jF_j
\]

(A.18)

are prevented by the additional \(U(1)\) symmetry. On the other hand, in flavor symmetries based models there are additional nonrenormalizable couplings which involve flavon fields and can generate proton decay operators. In our model, these nonrenormalizable operators up to order \(\mathcal{O}(1/\Lambda^2)\) look like \((1/\Lambda)10^i_m\bar{5}_m^i\bar{5}_m^j \Omega\) with \(\Omega = \varphi, \chi, \rho, \sigma, \eta\) as the various flavon superfields used throughout the different sectors studied in this work. It is easy to check from Tables \[III\] and \[IV\] that these couplings are also not allowed as they are not invariant under the \(U(1)\) symmetry.

Regarding the five-dimensional couplings \(\lambda^{ijkl}10^i_m10^j_m10^k_m\bar{5}_m^l\), they are mediated by the heavy color triplet Higgsino and it is well known that their dressing diagrams\(^2\) to form six-dimensional operators are the most disturbing operators that lead to fast proton decay in SUSY \(SU(5)\) models \[53, 56\]. These operators that are derived from the renormalizable up and down Yukawa couplings \(\lambda TTH_5\) and \(\lambda' TFH_5\) are absent in our model since they behave, respectively, as nontrivial singlets and triplet under the \(A_4\) flavor symmetry. However, the last couplings—which are required to generate masses for the charged fermions—are allowed through their interactions with the flavon superfields as given in the Yukawa couplings (A.10) and (A.6). Thus, our model contains higher order operators of the kind \(\frac{1}{M_T}TTTF \left(\frac{\Omega}{\Lambda}\right)^n\) where \(M_T\) is the mass of the colored Higgs triplet and \(n = 1, 2\); for \(n = 1\) we have \(\Omega = \eta\), and for \(n = 2\) the relevant combinations are \(\Omega^2 = \sigma\chi, \rho\chi, \eta\varphi\). Hence, the suppression of these operators compared to the usual five-dimensional couplings \(TTTF\) is now enhanced by the factors \(\left(\frac{\Omega}{\Lambda}\right)^n\) coming from the flavon superfields required by \(A_4\) invariance, thus

\(^2\) The dressing procedure of five-dimensional operators consists of converting two scalars (sfermions) in the \(TTTF\) couplings to two fermions by a loop diagram through the exchange of winos and Higgsinos—these are the dominant contributions to the operators \(qqql\) and \(u^c u^c d^c e^c\), respectively. For more details and examples on such diagrams see, for instance, Ref. \[54\].
leading to highly suppressed proton decay. We should note, however, that to provide precise
predictions for the proton decay rate, the renormalization group equations (RGEs) for the
gauge couplings at one loop must be taken into account [57]; this clearly goes beyond the
scope of this paper.
