Supplementary Text S1, Table S1, and Figures S1–S3

Text S1. Chemical analysis

Inorganic water-soluble ions in the samples were detected using an ion chromatograph (Dionex ICS-90, Sunnyvale, US). The anions, including F\textsuperscript{−}, Cl\textsuperscript{−}, NO\textsubscript{3}\textsuperscript{−}, and SO\textsubscript{4}\textsuperscript{2−}, were analyzed using an AS14A Column with an AMMS 300 Suppressor and were eluted with 3.5 mmol \textsuperscript{L}\textsuperscript{−1} Na\textsubscript{2}CO\textsubscript{3}-
1.0 mmol L$^{-1}$ NaHCO$_3$. The cations Na$^+$, NH$_4^+$, K$^+$, Mg$^{2+}$, and Ca$^{2+}$ were analyzed using a CS12A Column with a CSRS Ultra II Supresser and were eluted with 20 mmol L$^{-1}$ methanesulfonic acid.

A thermal-optical carbon aerosol analyzer (DRI Model 2001, Atmoslytic Inc., CA, USA) based on the thermal-optical transmittance method was used to determine the abundance of OC and EC. Full details of this instrument and analysis method can be found in Cheng et al (2009).

Teflon-membrane filters were analyzed by high-sensitivity X-ray fluorescence for Na, Mg, Al, Cl, K, Ca, Ti, V, Cr, Mn, Fe, Ni, Cu, Zn, Rb, Sb, Ba, Pb, etc (Cao et al. 2008).

Two typical anhydrosugars, levoglucosan (LG) and mannosan (MN), were measured by high-performance anion exchange chromatography with pulsed amperometric detection. Full details can be found in Zhang et al. (2010), but a brief description is provided here, as follows: A small punch from each quartz filter was extracted using 2.0 ml deionized water ($\Omega > 18.2$ M) under ultrasonic agitation for 1 h. The filter extracts were filtered to remove insoluble materials through Teflon syringe filters (pore size: 0.25 $\mu$m; PTFE, Whatman, USA) and were subsequently analyzed on a Dionex ICS-3000 system with a Dionex Carbopac MA1 analytical column (250 $\times$ 4 mm) using aqueous sodium hydroxide (NaOH) as eluent. The eluent was mixed in-line from 1000 mM NaOH and deionized water. A typical separation was carried out at eluent flow rate of 0.4 ml min$^{-1}$ for 60 min, including a 15 min equilibrium period (480 mM NaOH) before sample injection, a 30 min isocratic elution (480 mM NaOH) for separating most of the carbohydrates, and a 15 min gradient elution (from 480 to 650 mM NaOH). The limit of detection (LOD) for LG and MN was estimated to be 0.008 mg m$^{-3}$ and 0.004 mg m$^{-3}$, respectively, based on a signal-to-noise ratio of 3. The anhydrosugar contents in all field blanks
were lower than the LOD. The analytical errors of LG and MN were less than 10% (one relative standard deviation), based on analysis of replicate filter samples ($n = 8$).
