Abstract

Selection against hybridization can cause mating traits to diverge between species in sympatry via reproductive character displacement (RCD). Additionally, selection against interspecific fighting can cause aggressive traits to diverge between sympatric species via agonistic character displacement (ACD). By directly affecting conspecific recognition traits, RCD and ACD between species can also incidentally cause divergence in mating and fighting traits among populations within a species [termed cascade RCD (CRCD) and cascade ACD]. Here, we demonstrate patterns consistent with male-driven RCD and ACD in 2 groups of darters (orangemouth darter clade Ceasia and rainbow darter Etheostoma caeruleum). In both groups, males that occur in sympatry (between Ceasia and E. caeruleum) have higher levels of preference for mating and fighting with conspecifics over heterospecifics than do males from allopatry. This is consistent with RCD and ACD. We also found patterns consistent with CRCD and cascade ACD among species of Ceasia. Ceasia males that are sympatric to E. caeruleum (but allopatric to one another) also have heightened preferences for mating and fighting with conspecific versus heterospecific Ceasia. In contrast, Ceasia males that are allopatric to E. caeruleum readily mate and fight with heterospecific Ceasia. We suggest that RCD and ACD between Ceasia and E. caeruleum has incidentally led to divergence in mating and fighting traits among Ceasia species. This study is unique in that male preferences evolve via both RCD (male preference for conspecific females) and ACD (male preference to fight conspecific males) which leads to subsequent divergence among allopatric lineages.

Key words: agonistic character displacement, behavioral isolation, cascade reinforcement, reinforcement, reproductive character displacement, speciation.
between species that results in decreased heterospecific interactions in sympatry. Although numerous studies have shown that RCD can incidentally lead to divergence in mating traits among populations within species via CRCD, whether selection against interspecific aggression can also cause divergence in agonistic traits among populations within species (i.e., cascade ACD, hereafter CACD) has yet to be determined.

Distinguishing between RCD and ACD is essential to determining the underlying selective pressure (i.e., heterospecific mating or fighting) and relative contribution of male–female and male–male interactions in driving speciation. However, disentangling the importance of RCD versus ACD to speciation can be difficult because many sexually selected traits are used in both female mate choice and male–male competition over mates (Alatalo et al. 1994; Berglund 1996; Sætre et al. 1997; Dijkstra et al. 2007; Saether et al. 2007; Lackey and Boughman 2013; Tinghitella et al. 2015). Here, we examine female mating preferences, male mating preferences, and male–male aggression (MA) to test for patterns consistent with RCD, ACD, CRCD, and CACD.

This study focuses on 2 groups of darters in the subgenus Oligocephalus: the orangethroat darter clade Ceasia and the rainbow darter Etheostoma caeruleum. Ceasia and E. caeruleum diverged approximately 22 million years ago (Near et al. 2011). Time calibrated gene trees indicate that Ceasia subsequently diversified 6–7 million years ago (Bossu et al. 2013). The Ceasia clade consists of 15 species, all of which are allopatric with respect to one another (Ces and Page 1997; Bossu and Near 2009). Phylogenetic and palaeogeographical analyses support allopatric divergence of this clade (Bossu et al. 2013). Twelve Ceasia species occur in sympatry with respect to E. caeruleum throughout their range, and 2 Ceasia species occur in allopatry with respect to E. caeruleum throughout their range (see Bossu and Near 2009; Page and Burr 2011). The one remaining Ceasia species (orangethroat darter Etheostoma spectabile) occurs in both sympathy and allopatry with respect to E. caeruleum (Figure 1). Within Ceasia, time since divergence does not differ significantly between lineages that occur in sympathy versus allopatry with respect to E. caeruleum (Bossu et al. 2013). Ceasia and E. caeruleum have similar male coloration, mating behavior, and ecology. There is little evidence that male coloration in either Ceasia or E. caeruleum is the target of female mate choice; females lack preferences for either male size or color pattern within species, and Ceasia females lack preferences for conspecific over heterospecific Ceasia and E. caeruleum males (Pyron 1995; Fuller 2003; Zhou et al. 2015; Moran et al. 2017). Instead, there is
Table 1. Collection locations for populations of each species examined in behavioral trials in the present study as well as in Moran et al. (2017)

| Range map population number | Geography | Species | Collection location | Drainage information | Source of behavioral data |
|-----------------------------|----------|---------|---------------------|----------------------|--------------------------|
| 1                           | Allopatric | E. caeruleum | 42.426825, –85.428370 | Prairieville Creek, Kalamazoo River, Barry County, MI | Present study |
| 2                           | Sympatric | E. spectabile | 40.054447, –88.089887 | Unnamed tributary, Salt Fork of Vermillion River, Champaign County, IL | Present study and Moran et al. (2017) |
| 3                           | Sympatric | E. caeruleum | (Same as above) | (Same as above) | Present study and Moran et al. (2017) |
| 4                           | Allopatric | E. spectabile | 40.027663, –88.577180 | Unnamed tributary, Sangamon River, Piatt County, IL | Present study |
| 5                           | Allopatric | E. pulchellum | 38.952839, –95.517654 | Deer Creek, Kansas River, Shawnee County, KS | Present study Moran et al. (2017) |
| 6                           | Sympatric | E. fragi | 36.304214, –91.927684 | Rose Branch tributary of Strawberry River, Fulton County, AR | Moran et al. (2017) |
| 7                           | Sympatric | E. uniporum | 36.250560, –91.359318 | Unnamed tributary of Spring River, Sharp County, AR | Moran et al. (2017) |
| 8                           | Sympatric | E. caeruleum* | 36.065396, –91.610420 | Mill Creek tributary of Strawberry River, Sharp County, AR | Moran et al. (2017) |
| 9                           | Sympatric | E. burri | 37.146415, –90.907459 | North Fork Webb Creek, Black River Drainage, Wayne County, MO | Moran et al. (2017) |

Notes: Sympatry and allopatry refer to the geographic relationship between Ceasia and E. caeruleum (all species of Ceasia are allopatric from one another). Range map population number refers to numbers shown in Figure 1.

*Etheostoma caeruleum study population used in sympatric comparisons with Ceasia species from the Ozarks region (i.e., E. fragi, E. uniporum, and E. burri) in Moran et al. (2017).

strong evidence that male coloration is under intrasexual selection and functions as an aggressive signal in male–male competition over access to females (Zhou and Fuller 2016; Moran et al. 2017).

Several recent studies have indicated that RCD and ACD are likely occurring in this system. First, hybridization occurs between Ceasia and E. caeruleum in nature (Bossu and Near 2009; Moran et al. 2017), and their hybrids have reduced fitness (Zhou 2014; Moran R, unpublished data), providing the potential for RCD to occur via reinforcement (Brown and Wilson 1956; Coyne and Orr 2004). Second, in pairings between 4 species of Ceasia and sympatric E. caeruleum, males preferentially mate and fight with conspecifics, suggesting RCD and ACD (Figure 1 and Table 1; Moran et al. 2017). Third, a pattern consistent with RCD was observed in a no-choice mating experiment which found that allopatric pairings of female E. spectabile and male E. caeruleum yielded more eggs than sympatric pairings (Zhou and Fuller 2014). Zhou and Fuller (2014) is the only study to date to compare sympatric and allopatric pairings between a Ceasia species and E. caeruleum, but the no-choice assay they used was not able to measure the contribution of each sex to behavioral isolation in sympatry. Furthermore, Zhou and Fuller (2014) did not consider male competition, and could not test for ACD.

A unique aspect of this study system is that it allows us to test for patterns consistent with RCD and ACD at 2 taxonomic levels within Ceasia: populations within a species, and closely related species within a recently diverged clade. We first tested for RCD and ACD between populations of a single species of Ceasia as a function of sympatry with E. caeruleum. We next asked whether RCD and ACD are present between species of Ceasia as a function of sympathy with E. caeruleum. Most studies involving RCD and ACD have considered differences in mating traits between populations within a pair of species as a function of sympathy versus allopatry. However, RCD can also influence species diversification at a macroevolutionary scale (Pfenning and Pfennig 2012; Grether et al. 2017). Over time, CRCD and CACD can cause isolated populations within a species to diverge from one another to such an extent that they merit classification as distinct, allopatric species. The outcome of this process can result in a complex of closely related, allopatric species that exhibit enhanced mating trait divergence with one another (via CRCD/ACD), and with a more distantly related sympatric species (via RCD/ACD). In this manner, CRCD and CACD can fuel hierarchical “speciation cascades” among allopatric lineages at multiple taxonomic levels simultaneously (Pfenning and Ryan 2006). We hypothesize that this scenario is ongoing in the Ceasia–E. caeruleum system.

To test for RCD and ACD, we measured preferences for mating and fighting with conspecifics in pairings between E. spectabile and E. caeruleum that occur in sympathy versus allopatry with respect to one another. This allowed us to examine whether patterns consistent with RCD and ACD are present at the population level within E. spectabile and E. caeruleum. Additionally, we measured preferences for mating and fighting with conspecifics in pairings between Etheostoma pulchellum and E. caeruleum that occur in allopatry with respect to one another (Figure 1 and Table 1). Because E. pulchellum and E. caeruleum do not co-occur, these species should show a reduced level of bias against mating and fighting with one another compared with species of Ceasia and E. caeruleum that do co-occur. Measuring mating and fighting biases in allopatric pairings of Ceasia and E. caeruleum thus serves as a critical test against which we can compare levels of behavioral preferences in sympatric pairings of Ceasia and E. caeruleum that were previously reported by Moran et al. (2017).

We also investigated whether patterns consistent with CRCD and CACD are present among Ceasia species. Males within the
4 Ceasia species examined by Moran et al. (2017; Figure 1 and Table 1), which all occur in sympathy with respect to E. caeruleum, prefer conspecific over heterospecific Ceasia females and bias their aggression preferentially toward conspecific over heterospecific Ceasia males. This divergence in male mating and fighting traits among Ceasia species is not associated with differences in male color pattern or genetic distance. Therefore, RCD and ACD between Ceasia and E. caeruleum may have incidentally contributed to species divergence within the Ceasia clade via CRCD and CACD. To test this hypothesis, we examine preferences for mating and fighting with conspecifics (over a heterospecific member of the Ceasia clade) in pairings between E. spectabile and E. pulchellum that occur in allopatry with respect to E. caeruleum. We then ask whether E. spectabile and E. pulchellum have lower levels of preference for mating and fighting with conspecifics compared with that previously observed between pairs of Ceasia species that occur in sympathy with respect to E. caeruleum (Moran et al. 2017).

Materials and Methods

Mating system details

During the spring spawning season, Ceasia and E. caeruleum travel to shallow gravel riffles in headwater streams (Hubbs and Strawn 1957; Hubbs 1985). Females look for a suitable place to lay eggs by performing “nosedig” in which they jab their snout into the gravel. One to several males swim in tandem with a female as she searches for a spawning location. Males fight aggressively to ward off rival males by actively chasing them off and/or by flaring their dorsal and anal fins in a threat display. When the female is ready to spawn, she dives into the substrate, leaving only her head and caudal fin fully visible. Spawning initiates when a male positions himself above the female, and they release sperm and eggs into the substrate. Spawning often involves multiple males mating simultaneously with 1 female, and males sometimes exhibit sneaking behavior. Females will ovulate clutches of up to 200 eggs throughout the spawning season, but only release a few eggs per spawning bout (Heins et al. 1996; Fuller 1998). Hence, the female must spawn multiple times to fertilize all the eggs from a given clutch.

Study species/populations and collection locations

All Ceasia species occur in allopatry with respect to one another. Throughout the rest of this paper, the terms “allopatric” and “sympatric” refer to the geographic relationship between Ceasia and E. caeruleum (not between Ceasia species). To test for RCD and ACD between E. spectabile and E. caeruleum, we examined preferences for mating and fighting with conspecifics over heterospecifics in pairings between allopatric E. spectabile and allopatric E. caeruleum versus pairings between sympatric E. spectabile and sympatric E. caeruleum (Figure 1 and Table 1). We also tested for a pattern consistent with RCD and ACD in pairings between allopatric E. pulchellum and allopatric E. caeruleum (Figure 1 and Table 1). Finally, we tested for a pattern consistent with CRCD and CACD among Ceasia species by pairing allopatric E. spectabile with allopatric E. pulchellum (Figure 1 and Table 1).

We used 2 types of behavioral assays (“dichotomous male choice (MC) assay” and “male competition assay,” detailed below) to compare preferences for engaging in mating and fighting with conspecifics versus heterospecifics. We then compared these behavioral measurements to those documented in pairings between sympatric Ceasia and sympatric E. caeruleum, and pairings between sympatric Ceasia species, in Moran et al. (2017; Figure 1 and Table 1).

Fish were collected with a kick seine in March 2016 and April 2017 and transported back to the laboratory at the University of Illinois at Urbana-Champaign in aerated coolers. Fish were separated into stock aquarium according to population and sex, and were fed daily ad libitum with frozen bloodworms. Stock aquaria were maintained at 19°C and fluorescent lighting was provided to mimic the natural photoperiod.

Testing for RCD and ACD between Ceasia and E. caeruleum

Dichotomous MC assay

We first used a dichotomous MC assay to test for RCD in male mate choice. Each trial included a focal male E. spectabile or E. pulchellum with a conspecific female and a heterospecific (E. caeruleum) female (Figure 2A). This assay allowed males to choose between (1) sympatric E. spectabile and sympatric E. caeruleum, (2) allopatric E. spectabile and allopatric E. caeruleum, and (3) allopatric E. pulchellum and allopatric E. caeruleum females (n = 12 each). RCD predicts that preferences for conspecific mates should be higher in sympatric E. spectabile focal males than both allopatric E. spectabile and allopatric E. pulchellum focal males.

Behavioral trials occurred in 38 L test aquaria filled with 5 cm of naturally colored aquarium gravel. To minimize disturbance to the fish, test aquaria were covered with black opaque plastic on 3 sides. We used unique fish in each trial, chosen haphazardly from stock tanks. Females in each trial were size matched to within 10% of their total body length. Each trial began by placing the 3 fish being tested into a test aquarium and allowing them to acclimatize for 5 min. The trial then began and lasted 30 min. Each trial was broken up into 60 30-s blocks (Zhou et al. 2015; Moran et al. 2017).

We examined male mate choice by measuring focal male pursuit of each female in each trial. Male pursuit of a female is highly predictive of spawning in Ceasia and in E. caeruleum (Zhou et al. 2015; Moran et al. 2017). A male was scored as having pursued a female during a 30-s block if he spent a minimum consecutive time of 5-s within one body length of the female. We calculated a focal male mate choice behavioral variable from this data as described in Table 2.

We performed analyses using proportional data (i.e., the behavioral variables described in Table 2) that varied from 0 to 1. A score of 1 indicates only conspecific interactions occurred, 0.5 indicates an equal number of interactions between conspecifics and heterospecifics, and 0 indicates only heterospecific interactions occurred. However, for ease of interpretation, we graphed the raw number of behaviors observed.

We used analysis of variance (ANOVA) to test for RCD in male mating preference by asking whether focal male mate choice differed among the focal Ceasia study populations (i.e., sympatric E. spectabile, allopatric E. spectabile, and allopatric E. pulchellum). We included focal male mate choice as the dependent variable, and focal male population identity as the independent variable. We then used post hoc t-tests to directly compare populations. We also asked whether focal male mate choice differed from a null expectation of 0.5 (equal amounts of time spent with each female) in each population using one-sample t-tests.

Male competition assay

We conducted a second type of assay in which males could compete with one another to test for RCD and ACD. This assay paired (1)
in these species is complex and varies within populations (Zhou et al. 2014), allowing us to distinguish conspecific males. Males in each trial were size matched within 10% of their total body length to control for any larger differences in color pattern and competitive ability associated with body size (Zhou et al. 2014). In each trial, we measured the behavior of the focal female, the focal male, and the rival male. Due to low collection numbers, some allopatric E. caeruleum males were used twice, but never more than once on the same day or with the same Ceasia study population.

To test for ACD, we recorded the number of aggressive behaviors (i.e., fin flares and attacks) that both males in a trial directed toward the other male. We calculated 4 behavioral variables to quantify male aggressive bias toward conspecific males: focal male fin flare bias, focal male attack bias, rival male fin flare bias, and rival male attack bias (see Table 2). We asked whether these behavioral variables differed in sympatric versus allopatric pairings. To examine focal male Ceasia aggressive behavior, we conducted 2 separate ANOVAs with focal male fin flare bias and focal male attack bias as the dependent variables, and focal Ceasia male identity (sympatric E. spectabile, allopatric E. spectabile, or allopatric E. pulchellum) as the independent variable in both analyses. Similarly, to examine the aggressive behavior of E. caeruleum rival males relative to Ceasia rival males, we conducted ANOVAs with rival male fin flare bias and rival male attack bias as dependent variables, and focal Ceasia male identity as the independent variable. Additionally, we made pairwise comparisons among groups using post hoc 2-sample t-tests.

To test for RCD in male mate preference, we split each male competition trial into 60 30-s blocks (as in the dichotomous MC trials), and counted the number of 30-s blocks in which each male pursued the female. Unlike the dichotomous MC assay, the male competition assay considers the preference of male E. caeruleum for E. spectabile and E. pulchellum females. We calculated rival male mate choice as described in Table 2. As focal males were always paired with conspecific females in the male competition trials, we did not measure focal male mate choice in these trials. The male competition assay presented males with a no-choice situation, where they could choose whether to pursue a female. This assay also examined male mate preference in the presence of a male competitor, which is closer to what a male would experience in nature during the spawning season. We asked whether rival male mate choice differed between sympatric and allopatric trial sets. We conducted an ANOVA with rival male mate choice as the dependent variable and trial set (i.e., sympatric E. spectabile, allopatric E. spectabile, or allopatric E. pulchellum as the focal pair) as the independent variable, followed by pairwise post hoc 2-sample t-tests.

Finally, we tested for RCD in female mating preferences. The setup of the male competition assay was equivalent to a dichotomous female choice (FC) assay. We counted the number of nosedigs a female performed towards the rival male in each trial. Females typically perform nosedigs directly before spawning, and this behavior is often used to measure female mating preferences in darters (Fuller 2003; Williams and Mendelson 2011; Zhou et al. 2015; Zhou and Fuller 2016). We asked whether focal female mate choice (Table 2) differed among sympatric E. spectabile, allopatric E. spectabile, and allopatric E. pulchellum using ANCOVA. The model included focal female mate choice as the dependent variable and focal female identity as the independent variable. We included the proportion of time that conspecific rival males pursued the focal female as a covariate in the analysis, as male pursuit has been shown to predict female nosedigs and spawning (Zhou et al. 2015; Moran et al. 2017). We also used ANCOVA to test for focal female mate preference
for conspecific rival males versus \(E. \text{ caeruleum}\) rival males. The number of nosedigs the focal female directed toward each rival male was the independent variable, the rival male’s identity (conspecific or \(E. \text{ caeruleum}\)) was the dependent variable, and the proportion of time the rival male spent in pursuit of the female was included as a covariate. We note that although the females’ ability to exert mating preferences may be precluded by the outcome of male contests, male competition over females is pervasive in these species, so this assay reflects what females most frequently encounter in nature.

### Testing for CRCD and CACD between \(Ceasia\) species

#### Dichotomous MC assay

To test for patterns consistent with CRCD within \(Ceasia\), we paired allopatric \(E. \text{ spectabile}\) with allopatric \(E. \text{ pulchellum}\) in a dichotomous MC assay. We conducted this assay in the manner described above to test for RCD, but here the heterospecific female was an allopatric \(E. \text{ spectabile}\) or allopatric \(E. \text{ pulchellum}\), in place of an allopatric \(E. \text{ caeruleum}\) (Figure 2D). We performed trials in which allopatric \(E. \text{ spectabile}\) acted as the focal male and conspecific female, with \(E. \text{ pulchellum}\) as the heterospecific female, and vice versa (\(n = 12\) each). CRCD predicts no significant difference between allopatric \(E. \text{ spectabile}\) and allopatric \(E. \text{ pulchellum}\) in focal male mate choice (Table 2). To compare focal male mate choice between these species, we conducted ANOVAs that included focal male mate choice as the dependent variable and focal male identity (allopatric \(E. \text{ spectabile}\) or allopatric \(E. \text{ pulchellum}\)) as the independent variable. We also tested whether focal male mate choice for the conspecific female differed from a null expectation of 0.5 (equal amounts of time spent with each female) using one-sample \(t\)-tests.

#### Male competition assay

We also conducted a male competition assay between allopatric \(E. \text{ spectabile}\) and allopatric \(E. \text{ pulchellum}\) to test for patterns consistent with CRCD and CACD. Earlier work showed that \(Ceasia\) males that are sympatric with \(E. \text{ caeruleum}\) prefer to mate and fight with conspecifics over heterospecifics (Moran et al. 2017). Here, we asked whether \(Ceasia\) males that are allopatric with respect to \(E. \text{ caeruleum}\) lacked such preferences. We performed trials in which both allopatric \(E. \text{ spectabile}\) and allopatric \(E. \text{ pulchellum}\) acted as the focal pair and as the heterospecific rival male in turn (\(n = 12\) each; Figure 2E). CRCD and CACD predict that allopatric \(E. \text{ spectabile}\) and allopatric \(E. \text{ pulchellum}\) should show similarly low levels of preference for mating and fighting with conspecifics over heterospecifics. We measured rival male mate choice, and focal female mate choice, focal male fin flare bias, focal male attack bias, rival male fin flare bias, and rival male attack bias as described in Table 2. We conducted ANOVAs as described above for the male competition trials that tested for RCD and ACD, but with the appropriate species (i.e., \(E. \text{ spectabile}\) or \(E. \text{ pulchellum}\)) in place of \(E. \text{ caeruleum}\) as the heterospecific rival male.

We used ANOVA to test for RCD, ACD, CRCD, and CACD in both sets of dichotomous MC and male competition assays. Repeating all analyses using generalized linear models with a quasi-binomial error function and logit link function yielded qualitatively identical results.

---

**Table 2. Definition of the behavioral variables measured in the dichotomous MC assay and the male competition assay**

| Variable | Definition | RCD | ACD | CRCD | CACD |
|----------|------------|-----|-----|------|------|
| Dichotomous MC assay (2 females, 1 male) | | | | | |
| Focal Male Mate Choice | Number of time blocks spent pursuing the conspecific divided by the total number of time blocks spent pursuing either female. | Yes | NA | Yes | NA |
| Male competition assay (2 males, 1 female) | Proportion of time blocks the focal female was pursued by conspecific versus heterospecific rival males across 2 trials = Number of time blocks conspecific rival male pursued the female/sum of time blocks the conspecific and heterospecific rivals pursued the female. | Yes | NA | Yes | NA |
| Rival Male Mate Choice | Proportion of nosedigs towards conspecific versus heterospecific rival males across 2 trials = Number of nosedigs toward conspecific rivals/ (sum of nosedigs toward conspecific and heterospecific rivals); the analysis of this variable was corrected for male pursuit. | No | NA | No | NA |
| Focal Female Mate Choice | Proportion of time blocks spent pursuing the conspecific divided by the total number of time blocks spent pursuing either female. | Yes | NA | Yes | NA |
| Focal Male Fin Flare Bias | Proportion of fin flares toward conspecific versus heterospecific rivals across 2 trials = Number of fin flares to conspecific rival/sum of fin flares to conspecific and heterospecific rivals. | NA | Yes | NA | Yes |
| Focal Male Attack Bias | Proportion of attacks toward conspecific versus heterospecific rivals across 2 trials = Number of attacks on conspecific rival/sum of attacks on conspecific and heterospecific rivals. | NA | Yes | NA | Yes |
| Rival Male Fin Flare Bias | Proportion of nosedigs performed by conspecific versus heterospecific rivals across 2 trials = Number of nosedigs by conspecific rival toward the focal male/sum of nosedigs by conspecific and heterospecific rivals toward the focal male. | NA | Yes | NA | Yes |
| Rival Male Attack Bias | Proportion of attacks performed by conspecific versus heterospecific rivals across 2 trials = Number of attacks by conspecific rival toward the focal male/sum of attacks by conspecific and heterospecific rivals toward the focal male. | NA | Mixed\(^a\) | NA | Yes |

**Notes:** We indicate whether we observed a pattern consistent with predictions for RCD, ACD, CRCD, and CACD for each behavioral variable, or whether the behavioral variable was not applicable (NA) to testing a given prediction.

\(^a\)Allopatric \(E. \text{ caeruleum}\) males tended to attack allopatric \(E. \text{ spectabile}\) males more than sympatric \(E. \text{ caeruleum}\) males attacked sympatric \(E. \text{ spectabile}\) males, but no other differences were found.
Table 3. Results of ANOVA testing for RCD in focal Ceasia male mate choice between conspecific females and E. caeruleum females in dichotomous MC male trials

| Focal male mate choice                                      | df  | Test statistic | P     |
|------------------------------------------------------------|-----|---------------|-------|
| Focal Ceasia population identity                           | 2, 33 | 45.21        | <0.00001 |
| Sympatric E. spectabile versus allopatric E. spectabile    | 22  | 11.38        | <0.00001 |
| Sympatric E. spectabile versus allopatric E. pulchellum    | 22  | 8.10         | <0.00001 |
| Allopatric E. spectabile versus allopatric E. pulchellum   | 220 | -0.38        | 0.71   |

Notes: We asked focal male mate choice differed among focal Ceasia males in 3 study populations: sympatric E. spectabile, allopatric E. spectabile, and allopatric E. pulchellum. Pairwise post-hoc t-test results are also shown for the analysis.

Behavioral isolation indices

We used the MA, male mate choice, and female mate choice data from both sets of male competition assays (i.e., those testing for RCD and ACD, and those testing for CRCD and CACD) to calculate 3 behavioral isolation indices following Moran et al. (2017). Behavioral isolation indices were calculated individually for each trial and then averaged across all replicates within each species comparison. These indices allow for a comparison of levels of preference for mating and fighting with conspecifics over heterospecifics at a macroevolutionary scale among Ceasia–E. caeruleum and Ceasia–Ceasia species pairs. Indices range from 0 (complete preference for heterospecifics) to 1 (complete preference for conspecifics), with 0 indicating no preference for conspecifics versus heterospecifics (Stalker 1942; Martin and Mendelson 2016; Moran et al. 2017).

We calculated MA indices for each species pair as:

$$MA = \frac{a_c - a_h}{a_c + a_h}$$

where $a_c$ and $a_h$ represent the combined number of fin flares and attacks performed between conspecific males and between heterospecific males, respectively.

We calculated MC indices as:

$$MC = \frac{m_c - m_h}{m_c + m_h}$$

where $m_c$ and $m_h$ represent the proportion of time in each trial that conspecific males and heterospecific males spent pursuing the Ceasia female.

As previous studies have indicated that male pursuit of a female is highly correlated with female nosedigs (a measure of female mating preference), FC indices controlled for male pursuit of the female. We calculated the FC indices as:

$$FC = \frac{f_c - f_h}{p_c - p_h}$$

where $f_c$ and $f_h$ represent the number of nosedigs females performed toward conspecific males and toward heterospecific males, respectively. $p_c$ and $p_h$ represent the number of 30-s blocks in which conspecific males and heterospecific males were scored as having pursued the female during a trial, respectively.

We used ANOVA to make 2 sets of comparisons among the 3 types of behavioral isolation indices (i.e., MA, MC, and FC). First, we tested for differences between Ceasia and E. caeruleum pairs that occur in sympathy versus allopatry with respect to one another. RCD predicts higher MC and FC indices in Ceasia–E. caeruleum pairings that occur in sympathy versus allopatry, indicating enhanced mate preference for conspecifics. Similarly, divergent ACD predicts higher MA indices in Ceasia–E. caeruleum pairs that occur in sympathy versus allopatry. This would indicate that sympatric males bias their aggression more toward conspecifics over heterospecifics.

Second, we tested for differences between Ceasia and E. caeruleum species pairs that occur in sympathy versus allopatry with respect to E. caeruleum. RCD predicts higher MC and FC indices in Ceasia–E. caeruleum pairings that occur in sympathy with respect to E. caeruleum, indicating enhanced mate preference for conspecific over heterospecific Ceasia. Likewise, CACD predicts higher MA indices in Ceasia–E. caeruleum pairings that occur in sympathy with respect to E. caeruleum. This would indicate that Ceasia males that occur in sympathy with respect to E. caeruleum bias their aggression more toward conspecific males versus heterospecific Ceasia males.

For all analyses, we used Type III sums of squares using the “car” package in R (version 3.4.0). Raw data have been deposited in Dryad (doi:10.5061/dryad.g8d1v).

Results

RCD between Ceasia and E. caeruleum

The dichotomous MC trials revealed a pattern consistent with RCD in focal Ceasia male mate preference. RCD predicts that MC for conspecifics should be heightened in Ceasia populations/species that are sympatric with respect to E. caeruleum. Focal male mate choice was 2× higher in sympatric E. spectabile compared with allopatric E. spectabile and allopatric E. pulchellum, but did not differ between allopatric E. spectabile and allopatric E. pulchellum (Table 3 and Supplementary Figure S1a). In addition, focal male mate choice was much greater than the null expectation of 0.5 in trials with sympatric E. spectabile serving as the focal male (mean ± SE: 0.97 ± 0.01; one-sample t-test: $t_{11} = 51.58, P < 0.00001$). Conversely, focal male mate choice did not differ from 0.5 in trials where allopatric E. spectabile and allopatric E. pulchellum served as the focal male (Supplementary Figure S1b, c; allopatric E. spectabile mean ± SE: 0.51 ± 0.04; one-sample t-test: $t_{11} = 0.17, P = 0.87$; E. pulchellum mean ± SE: 0.53 ± 0.05; one-sample t-test: $t_{11} = 0.60, P = 0.56$).

RCD in male mate preference was also indicated in the male competition trials, which compared E. caeruleum rival male preference for the focal Ceasia female with that of the conspecific Ceasia rival male. RCD predicts that sympatric E. caeruleum males should be less likely to pursue Ceasia females than allopatric E. caeruleum males. Rival male mate choice differed significantly between sympatric and allopatric E. caeruleum (Supplementary Table S1). In trials where sympatric E. spectabile served as the focal Ceasia pair, conspecific rival males were much more likely to pursue the focal female compared with the sympatric E. caeruleum rival males (Supplementary Figure S2a). In both trials where allopatric
E. spectabile and E. pulchellum served as the focal Ceasia pair, conspecific rival males and allopatric E. caeruleum rival males spent roughly the same amount of time pursuing the focal female (Supplementary Figure S2b, c). Hence, allopatric E. caeruleum males chose to pursue allopatric E. spectabile and allopatric E. pulchellum females. Sympatric E. caeruleum males largely ignored sympatric E. spectabile females.

We did not find support for RCD in female mating preferences in the male competition trials. When male pursuit was included as a covariate in the analysis, focal female mate choice did not differ among the sympatric E. spectabile, allopatric E. spectabile, and allopatric E. pulchellum trials (Table 4). Females did not exert preference for conspecific males over E. caeruleum males, regardless of sympathy with respect to E. caeruleum (Supplementary Table S2).

ACD between Ceasia and E. caeruleum

The aggressive behavior of focal Ceasia males in the male competition trials was consistent with divergent ACD. Divergent ACD predicts that Ceasia males that are sympatric with respect to E. caeruleum should bias their aggression toward conspecific rival males over E. caeruleum rival males. Focal male fin flare bias and focal male attack bias were higher for sympatric E. spectabile compared with allopatric E. spectabile and allopatric E. pulchellum (Table 5). Sympatric E. spectabile focal males directed 9× more fin flares toward conspecific (versus E. caeruleum) rival males (Supplementary Figure S1d). Similarly, sympatric E. spectabile focal males attacked conspecific rival males 6× more than they attacked sympatric E. caeruleum rival males (Supplementary Figure S1g). On average, both allopatric E. spectabile and allopatric E. pulchellum focal males directed an equal number of fin flares (Supplementary Figure S1e, f) and attacks (Supplementary Figure S1h, i) toward conspecific rival males and allopatric E. caeruleum rival males.

We also found a pattern consistent with divergent ACD in E. caeruleum male aggressive behavior. Divergent ACD predicts that sympatric E. caeruleum rival males should show higher levels of aggression toward focal male Ceasia compared with allopatric E. caeruleum rival males. Rival male fin flare bias showed a pattern like that found with focal Ceasia males (Supplementary Table S3). Sympatric E. caeruleum rival males were much less likely to flare their fins toward E. spectabile focal males compared with allopatric E. caeruleum rival males (Supplementary Figure S2d, f).

Conversely, rival male attack bias did not differ between sympatric and allopatric E. caeruleum (Supplementary Table S3). Both sympatric and allopatric E. caeruleum rival males directed a low number of attacks toward the focal Ceasia males (Supplementary Figure S2g, i). Thus, while allopatric E. spectabile and allopatric E. pulchellum focal males did not bias their aggression more toward conspecific rival males (versus allopatric E. caeruleum rival males; see previous paragraph), allopatric E. caeruleum rival males typically preferred not to attack allopatric E. spectabile and allopatric E. pulchellum focal males.

CRCD between Ceasia species

CRCD predicts that males from Ceasia species that are sympatric with respect to E. caeruleum should show higher levels of male mate preference for conspecific females over heterospecific Ceasia females, despite the fact that the 2 Ceasia species are allopatric with respect to one another. Moran et al. (2017) showed that in Ceasia species that are sympatric with respect to E. caeruleum, male mate preference for conspecific over heterospecific Ceasia females was surprisingly high. This study shows that male Ceasia (i.e., E. spectabile

Table 4. Results ANCOVA testing for RCD in focal Ceasia female mate choice between conspecific rival males and E. caeruleum rival males in male competition trials

| Focal female mate choice | df | Test statistic | P  |
|--------------------------|----|---------------|----|
| Focal Ceasia population identity | 2, 32 | 0.09 | 0.92 |
| Male pursuit | 1, 32 | 0.74 | 0.40 |

Notes: We asked whether focal female mate choice differed among focal Ceasia females in 3 study populations: sympatric E. spectabile, allopatric E. spectabile, and allopatric E. pulchellum. Male pursuit of the female was included as a covariate in the analysis.

Figure 3. Patterns of RCD and ACD between Ceasia and E. caeruleum. Behavioral isolation indices (with 95% confidence intervals) for (A) MA, (B) MC, and (C) FC for comparisons between Ceasia species and E. caeruleum. Allopatric comparisons (i.e., those including Ceasia and E. caeruleum that occur in allopatry with respect to one another) are shown in black. Sympatric comparisons (i.e., those including Ceasia and E. caeruleum that occur in sympatry with respect to one another) are shown in white. Grouping bars are also used to indicate allopatric species pairs (left) versus sympatric species pairs (right). Significance levels from ANOVAs comparing allopatric and sympatric species pairs are shown.
and *E. pulchellum* that are allopatric with respect to *E. caeruleum* do not prefer conspecific over heterospecific *Ceasia* females. In dichotomous MC trials, focal male mate choice did not differ between allopatric *E. spectabile* and allopatric *E. pulchellum* (*F*<sub>1,22</sub> = 0.29; *P* = 0.60; Supplementary Figure S3a, b). Additionally, focal male mate choice did not differ from a null expectation of 0.5 in allopatric *E. spectabile* (mean ± SE: 0.42 ± 0.04; one-sample *t*-test: *t*<sub>11</sub> = −1.94, *P* = 0.08) or in allopatric *E. pulchellum* (mean ± SE: 0.45 ± 0.04; one-sample *t*-test: *t*<sub>11</sub> = −1.28, *P* = 0.23). Similarly, in the male competition trials rival male mate choice did not differ between allopatric *E. spectabile* and allopatric *E. pulchellum* (*F*<sub>1,22</sub> = 0.12; *P* = 0.73; Supplementary Figure S4).

In contrast, there was no evidence for CRCD in female mating preference. Focal female mate choice did not differ between allopatric *E. spectabile* and allopatric *E. pulchellum*, and these preferences did not differ from 0.5 (Supplementary Table S4). There was no significant difference in the proportion of female nosedigs toward rival males as function of their identity (conspecific or heterospecific) when we controlled for the proportion of time each male pursued the female (Supplementary Table S5).

### CACD between *Ceasia* species

CACD predicts that *Ceasia* males that are sympatric with respect to *E. caeruleum* should bias their aggression toward conspecific over heterospecific *Ceasia* males, despite the fact that the 2 *Ceasia* species are allopatric with respect to one another. CACD also predicts that *Ceasia* males that are allopatric with respect to *E. caeruleum* should not bias their aggression more toward conspecific versus heterospecific males. Moran et al. (2017) paired *Ceasia* species that occur in sympathy with respect to *E. caeruleum* and found high levels of male preference for fighting with conspecific over heterospecific *Ceasia* males. Here, we show that *Ceasia* species (i.e., *E. spectabile* and *E. pulchellum*) that are allopatric with respect to *E. caeruleum* show no such male bias in aggressive behavior. Focal male fin flare bias did not differ between allopatric *E. spectabile* and allopatric *E. pulchellum* (*F*<sub>1,22</sub> = 1.79; *P* = 0.19; Supplementary Figure S3c, d), nor did focal male attack bias (*F*<sub>1,22</sub> = 0.84; *P* = 0.37; Supplementary Figure S3e, f).

Rival male behavior showed a similar pattern consistent with CACD. In the trials where allopatric *E. pulchellum* served as focal males, both conspecific *E. pulchellum* rival males and the allopatric *E. spectabile* rival males directed a similar number of fin flares toward focal males (Supplementary Figure S4d). However, in trials where allopatric *E. spectabile* served as focal males, the allopatric *E. pulchellum* rival males directed more fin flares toward the focal males compared with the conspecific *E. spectabile* rival males (Supplementary Figure S3c). This resulted in a significant difference in rival male fin flare bias between allopatric *E. spectabile* and allopatric *E. pulchellum* (*F*<sub>1,22</sub> = 5.79; *P* = 0.025; Supplementary Figure S4), despite the pattern being consistent with the prediction for CACD. Rival male attack bias did not differ between trials with allopatric *E. spectabile* versus allopatric *E. pulchellum* serving as the focal male (*F*<sub>1,22</sub> = 0.10; *P* = 0.75; Supplementary Figure S4).

### Behavioral isolation indices

To examine macroevolutionary patterns of RCD and ACD among *Ceasia–E. caeruleum* species pairs, and CRCD and CACD among *Ceasia–Ceasia* species pairs, we compared the behavioral isolation indices calculated in this study with behavioral isolation indices calculated by Moran et al. (2017; Table 6 and Figures 3 and 4). The pattern in male mating preference was consistent with RCD between *Ceasia* and *E. caeruleum* species pairs and CRCD between *Ceasia* and *Ceasia* species pairs. MC indices were consistently higher between sympatric species pairs compared with allopatric species pairs, signifying enhanced preference for mating with conspecifics in sympathy. RCD was indicated in the *Ceasia–E. caeruleum* comparisons as MC was higher for sympatric compared with allopatric species pairs (*F*<sub>1,82</sub> = 56.35, *P* < 0.0001; Figure 3). CRCD was indicated in the *Ceasia–Ceasia* comparisons as male *Ceasia* that are sympatric with respect to *E. caeruleum* had heightened MC indices, despite the fact that all *Ceasia* are allopatric to one another (*F*<sub>1,79</sub> = 6.64, *P* = 0.01; Figure 4). The difference in MC indices in sympathy versus allopatry was greater in *Ceasia–E. caeruleum* pairings than in *Ceasia–Ceasia* pairings (Table 6).

Conversely, we did not observe a pattern consistent with RCD or CRCD in female mating preferences. FC indices did not differ as a function of sympathy with respect to *E. caeruleum* in *Ceasia–E. caeruleum* (*F*<sub>1,82</sub> = 0.96, *P* = 0.33) or *Ceasia–Ceasia* comparisons (*F*<sub>1,79</sub> = 0.18, *P* = 0.67; Table 6 and Figures 3 and 4). This was due to females not exerting any detectable mating preferences for conspecific males.

We observed a pattern consistent with divergent ACD between *Ceasia* and *E. caeruleum* species pairs and CACD between *Ceasia* and *Ceasia* species pairs. MA indices were consistently higher between sympatric species pairs compared with allopatric species pairs, indicating increased male preference for fighting with conspecific over heterospecific males in sympathy. This pattern was present both within the *Ceasia–E. caeruleum* comparisons (*F*<sub>1,166</sub> = 136.30, *P* < 0.0001; Figure 3; indicating ACD) and within the *Ceasia–Ceasia* comparisons (*F*<sub>1,142</sub> = 34.17, *P* < 0.0001; Figure 4; indicating CACD).

### Table 5: Results of ANOVA testing for ACD in focal *Ceasia* MA bias in male competition trials

| Focal male fin flare bias                        | df       | Test statistic | *P*   |
|-----------------------------------------------|----------|----------------|-------|
| Focal *Ceasia* population identity            | 2, 33    | 8.34           | 0.0012|
| Sympatric *E. spectabile* versus allopatric *E. spectabile* | 22       | 5.28           | <0.0001|
| Sympatric *E. spectabile* versus allopatric *E. pulchellum* | 22       | 2.85           | 0.0093|
| Allopatric *E. spectabile* versus allopatric *E. pulchellum* | 22       | −0.84          | 0.41  |

*Notes:* We asked whether focal male fin flare bias and focal male attack bias differed among focal *Ceasia* males in 3 study populations: sympatric *E. spectabile*, allopatric *E. spectabile*, and allopatric *E. pulchellum*. Pairwise post-hoc *t*-test results are also shown for both analyses.
MA was higher between sympatric *Ceasia* and *E. caeruleum* pairs than it was in sympatric *Ceasia* and *Ceasia* pairs (Table 6).

**Discussion**

Striking patterns of RCD and ACD driven by male behavior are present at 2 taxonomic levels within *Ceasia*. First, we found evidence for both RCD and ACD among populations within species (Figure 3 and Supplementary Figure S1; Table 2). We observed RCD in male mate choice among populations of *E. spectabile* and *E. caeruleum*. Male (but not female) preference for conspecific mates was enhanced in sympatric (versus allopatric) population pairings of these species (Tables 3, 4, and Supplementary Table S2). We also found evidence of divergent ACD among populations within *E. spectabile* and *E. caeruleum*. Males preferentially biased their aggression toward conspecific males to a greater extent in sympatric population pairings (Table 5). Second, we found evidence for ACD and RCD among closely related species in the *Ceasia* species complex. Males showed no preference for mating (Table 3) or fighting (Table 5) with conspecifics over heterospecifics in pairings of allopatric *E. pulchellum* and allopatric *E. caeruleum*. This stands in contrast to the results of Moran et al. (2017), which found high levels of male preference for mating and fighting with conspecifics over heterospecifics in sympatric pairings of *Ceasia* species and *E. caeruleum*. We discuss how the data from the present study and Moran et al. (2017) reveal a pattern consistent with RCD and ACD at a macroevolutionary scale between *Ceasia* species and *E. caeruleum* (see below).

Most of our efforts were directed at testing for RCD and ACD in *Ceasia*. However, we also found evidence for RCD in male mate choice (Supplementary Figure S2 and Table S1) and ACD in MA bias in *E. caeruleum* (Supplementary Figure S2 and Tables S3), but the pattern of divergent ACD observed in male *E. caeruleum* pairs...
behavior was not as extreme as that observed in *Ceasia*. ACD was indicated in *E. caeruleum* in that sympatric male *E. caeruleum* were less likely to flare their fins at sympatric male *E. spectabile*, but *E. caeruleum* males from both sympatric and allopatric populations did not perform many attacks toward *E. spectabile* or *E. pulchellum* males. We hypothesize that this difference may be related to the level of gene flow present between populations of *Ceasia* species versus *E. caeruleum*. RCD and ACD are more likely to be maintained over time (and to lead to CRCD and CACD) when gene flow is low among populations within species (Yukilevich and Aoki 2016). *Ceasia* and *E. caeruleum* both occur in small headwater streams, but *E. caeruleum* can also inhabit larger order streams and rivers (Page 1983), leading to more opportunities for gene flow among populations (Echelle et al. 1975, 1976). Gene flow from sympatric to allopatric populations of *E. caeruleum* may result in the loci for MA bias spreading beyond the zone of sympathy. Indeed, population genetic analyses of 4 species of *Ceasia* and *E. caeruleum* found increased heterozygosity and higher levels of nucleotide diversity present in *E. caeruleum* compared with *Ceasia* (Moran et al. 2017), indicating lower levels of gene flow in species of *Ceasia*.

We also tested for patterns consistent with CRCD and CACD between species of *Ceasia* (Table 2 and Figure 4). We observed that allopatric *E. spectabile* and allopatric *E. pulchellum* males showed no preference for conspecific over heterospecific *Ceasia* females, nor did they bias their aggression more toward conspecific over heterospecific *Ceasia* males (Supplementary Figures S3 and S4). Our previous work indicated that sympatric *Ceasia* species have a clear preference to mate and fight with conspecific over heterospecific *Ceasia* (Moran et al. 2017). Together, these data reveal a clear pattern of CRCD in male mate choice and CACD in MA among *Ceasia* species (see below).

**Relationship to previous studies in darters**

Considering our results together with those of a recent study by Moran et al. (2017) reveals 2 macroevolutionary patterns: (1) RCD and ACD are present between species of *Ceasia* and *E. caeruleum* and (2) cascading effects of RCD and ACD between *Ceasia* and *E. caeruleum* have incidentally contributed to allopatric divergence among closely related lineages within the *Ceasia* clade (i.e., CRCD and CACD). RCD and ACD are indicated in that *Ceasia* species that occur in sympathy with *E. caeruleum* consistently show almost complete preference for mating and fighting with conspecifics over *E. caeruleum*, but no such preferences exist in *Ceasia* species that occur in allopatry with *E. caeruleum* (this study; Zhou and Fuller 2014). Similarly, CRCD and CACD are indicated in that *Ceasia* species that occur in sympathy with *E. caeruleum* (but allopatry with respect to one another) show surprisingly high levels of male preference for mating with and fighting with conspecifics over heterospecific *Ceasia*, but these preferences are absent in pairings of *Ceasia* that occur in allopatry with respect to *E. caeruleum* (this study; Moran et al. 2017). Future studies should determine whether patterns of CRCD and CACD are also present among populations within individual species of *Ceasia* (as is the case with RCD and ACD within *E. spectabile*).

This study corroborates the results of several recent studies which have shown that male mate choice and male competition play an important role in driving sympatric and allopatric trait divergence in darters (Cicotto et al. 2013; Zhou et al. 2015; Zhou and Fuller 2016; Martin and Mendelson 2016; Moran et al. 2017). Furthermore, although the presence of elaborate male coloration is typically attributed to intersexual selection via female mate preferences (Panhuis et al. 2001), male coloration in darters appears to be under intrasexual selection due to intense male–male competition. RCD and ACD can lead to shifts in behavioral response to heterospecifics and in the signals used in species recognition (Brown and Wilson 1956; Grether et al. 2009). Thus, examining whether character displacement in male color pattern corresponds to the observed ACD and CACD in male aggressive response to heterospecifics would be of interest.

Our results also uphold previous examinations of female mate choice in this system, which have consistently failed to detect female preferences for conspecific males in sympatric or allopatric pairings of *Ceasia* and *E. caeruleum* (Pyron 1995; Fuller 2003; Zhou et al. 2015; Moran et al. 2017). FC may be prevented by the presence of intense male competition in these species. Further study is needed to determine whether females exhibit any cryptic forms of mate choice (Eberhard 1996), such as adjusting the number of eggs laid when mating with conspecific versus heterospecific males.

**Selection underlying RCD and ACD**

The presence of hybridization in conjunction with high levels of postzygotic isolation between *Ceasia* and *E. caeruleum* (Zhou 2014; Moran R, unpublished data) suggests that RCD in these species may occur via reinforcement. Selection for males to prefer conspecific mates (to avoid maladaptive hybridization) would establish females as an unshared resource between species, making interspecific fighting over females costly. Theoretical treatments of ACD predict that selection may favor divergence in male aggressive traits between species when males compete for separate resources (i.e., females), which decreases the prevalence of interspecific aggression in sympathy (Okamoto and Grether 2013). In the case of *Ceasia* and *E. caeruleum*, a lowered aggressive response to heterospecific males may also facilitate their co-occurrence within the same habitat in sympatric drainages. The fact that the 2 species can co-occur in sympathy provides further opportunities for interspecific encounters and hybridization, further strengthening selection for divergence in mating traits and behavioral isolation via RCD. In this manner, RCD and ACD may strengthen one another in a positive feedback loop. There is evidence for such a feedback loop scenario between types of character displacement acting in *Ficedula* flycatchers (Qvarnström et al. 2012; Vallin et al. 2012).

**Selection underlying CRCD and CACD**

Theory predicts that CRCD or CACD can occur when populations stochastically respond to selection on mating and fighting traits in unique ways during RCD and ACD (i.e., mutation-order selection; Abbott et al. 2013; Mendelson et al. 2014; Comeault and Matute 2016). Under mutation-order selection, trait divergence may occur despite the presence of similar types of ecological and sexual selection. In this way, stochastic variation in response to the same selective pressures (i.e., maladaptive heterospecific interactions in sympathy) can potentially lead to allopatric divergence among populations within species.

Although theory predicts that CRCD and CACD can lead to allopatric speciation (McPeek and Gavrilets 2006; Pfennig and Ryan 2006), the majority of empirical studies that have examined CRCD and CACD to date have only tested for differences in behavioral preferences among populations within species. In addition, many studies have tested for CRCD by comparing levels of behavioral isolation between populations within species that are allopatric versus sympatric with respect to another species (Nosil et al. 2003;
The implication with these studies is that RCD changes mating traits in such a way that increases behavioral isolation between sympatric and allopatric populations within a species (i.e., “sympathy–allopatry effects”). In Ceasia and E. caeruleum, there are high levels of preferences for mating and fighting with conspecifics in pairings between Ceasia species that have independently undergone RCD and ACD with E. caeruleum. This suggests that different species-specific traits have evolved in Ceasia species that are sympatric with respect to E. caeruleum (i.e., “convergent-sympathy effects”).

Conclusions

This study provides empirical evidence of male-driven RCD, ACD, CRCD, and CACD in darters. As far as we are aware, this is the first documented case demonstrating that ACD between species can incidentally lead to CACD among populations within species (or in this case, among closely related species within a clade). Although the clear majority of RCD studies to date have focused on the evolution of female mating preferences for males, the results of this study demonstrate that male behavior can drive trait divergence between and within species via RCD and CRCD. This underscores the necessity of considering the behavior of both sexes when evaluating character displacement in a given system. Finally, this study provides important groundwork for future studies examining the extent to which RCD and ACD have been involved in generating the extraordinary species diversity present in darters.
