Rigorous justification of the Whitham modulation theory for equations of NLS type

W.A. Clarke  |  R. Marangell

Abstract
We study the modulational stability of periodic travelling wave solutions to equations of nonlinear Schrödinger type. In particular, we prove that the characteristics of the quasi-linear system of equations resulting from a slow modulation approximation satisfy the same equation, up to a change in variables, as the normal form of the linearized spectrum crossing the origin. This normal form is taken from Stability of Travelling wave solutions of Nonlinear Dispersive equations of NLS type, where Leisman et al. compute the spectrum of the linearized operator near the origin via an analysis of Jordan chains. We derive the modulation equations using Whitham’s formal modulation theory, in particular the variational principle applied to an averaged Lagrangian. We use the genericity conditions assumed in the rigorous theory of Leisman et al. to direct the homogenization of the modulation equations. As a result of the agreement between the equation for the characteristics and the normal form from the linear theory, we show that the hyperbolicity of the Whitham system is a necessary condition for modulational stability of the underlying wave.

1 | INTRODUCTION

In this paper, we consider the modulational stability of periodic solutions to equations of nonlinear Schrödinger type

\[ i\psi_t = \psi_{xx} + \zeta f(|\psi|^2)\psi \]  

under perturbations in \( L_2(\mathbb{R}) \). The nonlinearity \( f(|\psi|^2) \) is arbitrary, but assumed to be well-behaved (double-integrable) as in Ref. 1. This equation has a rich history of study; the cubic nonlinear Schrödinger equation, \( f(|\psi|^2) = \pm |\psi|^2 \), describes the envelope of a slowly modulated carrier wave in a dispersive medium.\(^2,3\) This equation, and others of NLS-type with higher order nonlinearities, arise in the study of a plethora of physical systems, including water waves\(^4,5\); nonlinear optics\(^6,7\); plasma physics\(^8–10\); and Bose–Einstein condensates.

Since the dynamics of Equation (1) exhibit linear, nonlinear and modulatory behavior, the literature includes analyses of linearized, orbital, and modulational stability. If one chooses a suitable potential \( f(|\psi|^2) \) such that Equation (1) is integrable, then it is possible to give an explicit description of the spectrum. The cubic nonlinear Schrödinger equation is the best example of this,\(^13,14\) however, relying on integrability is not necessary.\(^15\) Rowlands determined the spectral stability of stationary periodic solutions of the cubic nonlinear Schrödinger equation subject to long-wavelength disturbances,\(^16\) and in so doing demonstrated modulational instability in the focusing case. Alfimov, Its and Kulagin\(^17\) constructed the homoclinic orbit for an unstable, spatially periodic solution to the focusing nonlinear Schrödinger equation, essentially providing a nonlinear description of the modulational stability of this type of solution. Using the general methods of Refs. 18, 19, Gallay and Hărăguş proved that quasiperiodic, small-amplitude solutions to the cubic nonlinear Schrödinger equation are orbitally stable within the class of solutions having the same period and Floquet multiplier.\(^20\) They further proved that these solutions are linearly stable under bounded perturbations in the defocusing case, but linearly unstable in the focusing case. In Ref. 21, Gallay and Hărăguş extend the orbital stability results in Ref. 20 to solutions of any amplitude.

This paper deals with modulational stability of Equation (1), that is, the spectral stability subject to long-wavelength perturbations. Rigorously speaking, this amounts to expanding the spectrum of the linearized operator in a neighborhood of the origin in the spectral plane. Whitham modulation theory\(^22–26\) provides a formal procedure in which the modulational stability is computed by considering the hyperbolicity of a system of PDEs called the Whitham modulation equations. These modulation equations arise from an asymptotic expansion of the governing PDE via \((x, t) \mapsto (\varepsilon x, \varepsilon t)\) along with a WKB approximation of the solution. To \( O(\varepsilon) \), these equations are a homogeneous system of PDEs in terms of the slowly varying parameters of the original PDE. Proving that the Whitham modulation theory accurately predicts the results of the rigorous analysis of the linearized spectrum is nontrivial, and to our knowledge is an open problem in the general case. Our present analysis is influenced by the examples of where this has been done, such as: the nonlinear Klein–Gordon equation\(^27\); the generalized Korteweg-de Vries equation\(^28\); systems of viscous conservation laws\(^29,30\); and a viscous fluid conduit equation.

In addition to the WKB approximation and asymptotic expansion, Whitham proves that there are several other equivalent methods for deriving the Whitham modulation equations.\(^25,26\) In particular, these are: the variational principle applied to an averaged Lagrangian; and averaging and two-timing a system of conservation laws. As a result of unwieldy algebra that arises in the modulation equations, one often chooses the method that provides the simplest derivation of the Whitham modulation equations, thereafter making a change of variables in order to prove that
the hyperbolicity of the Whitham system is equivalent to the linearized stability theory. When the modulational instability criterion from the linearized stability theory is given in terms of the derivatives of special quantities of the original PDE such as the period, mass, and momentum, a useful technique is to introduce a classical action variable \( W \), since the derivatives of \( W \) are related to these special quantities. This is the case for both the nonlinear Klein–Gordon equation\(^{27} \) and the generalized Korteweg-de Vries equation.\(^{28,32} \) This approach relies on the symmetry properties of Lagrangian systems, and Whitham in fact derives the modulation equations using the averaged Lagrangian method in the cases of both of these PDEs (only the nongeneralized case for KdV).\(^{26} \) Equation (1) admits a Lagrangian (cf. Equation (26)), and so we follow the averaged Lagrangian method in order to more easily derive the Whitham modulation equations. If, however, there is not an obvious Lagrangian but the travelling wave ODE is integrable, one can compute the tangent space to the manifold of travelling wave solutions and construct the kernel of the linearized operator from a basis of the tangent space. In Ref. \(^{30} \), Serre performs this exact procedure to prove that the hyperbolicity criterion of the Whitham modulation equations agrees with the rigorous modulational stability analysis (as determined from an Evans function expansion) of a system of scalar, viscous conservation laws,\(^{33} \) which is later extended to the multi-dimensional case.\(^{29} \) For the conduit equation, which is neither completely integrable nor Lagrangian in structure, Johnson and Perkins rigorously derive a matrix encoding the leading order asymptotics of the spectral curves at the origin via Floquet–Bloch theory and spectral perturbation theory.\(^{31} \) The entries of this matrix agree exactly with the coefficients of the Whitham system, allowing for a more direct comparison of modulational instability criteria.

There is a well-developed Whitham modulation theory for the nonlinear Schrödinger equation; Düll and Schneider proved that solutions to the Whitham modulation equations that are analytic in a strip are a valid approximation of spatial and temporal modulations of periodic wave solutions of the cubic nonlinear Schrödinger equation.\(^{34} \) A similar result exists for solutions to multi-phase Whitham modulation equations in the context of coupled NLS equations.\(^{35} \) In the context of Sobolev spaces, proving that solutions to the Whitham modulation equations are a valid approximation to modulations of a periodic wavetrain requires spectral stability of the underlying wavetrain, and so Bridges \textit{et al.} restricted their analysis to hyperbolic Whitham modulation equations for the defocusing NLS equation.\(^{36} \) In Refs. \(^{37,38} \), the authors investigate the transition between a hyperbolic and elliptic system of Whitham modulation equations for cubic NLS in the single phase case and a coupled NLS system in the multiphase case. In Ref. \(^{39} \), Kamchatnov provides techniques for calculating the Riemann invariants of the cubic nonlinear Schrödinger equation, from which the hyperbolicity of the Whitham modulation equations can be determined. Moreover, the Riemann invariants of a Whitham modulation system encode the asymptotic description of a dispersive shock wave; El and Hoefer provide an extensive discussion on this connection in Ref. \(^{40} \) as well as an analysis of dispersive shock waves in the case of cubic NLS and numerical simulations of dispersive shock wave behavior for Equation (1). El and Hoefer also note that applying the Madelung transformation (\( \psi = \sqrt{\rho} e^{i\phi} \)) to Equation (1) yields the hydrodynamic system:

\[
\rho_t + (\rho u)_x = 0 \tag{2}
\]

\[
(\rho u)_t + (\rho u^2 + P(\rho))_x = (\rho (\ln \rho)_{xx})_x \tag{3}
\]

with \( P(\rho) = \int_0^\rho 2s f'(s) ds \) and \( u = -\phi_x \). Serre’s results\(^{30} \) are not proven to extend to higher order dispersive terms such as \( \rho (\ln \rho)_{xx} \). We also point out that, as an intermediate step in deriv-
ing Equations (2) and (3), we can write Equation (1) as an Euler–Korteweg system in Eulerian coordinates:\(^{41}\):

\[ \rho_t + (\rho u)_x = 0 \]  
\[ u_t + uu_x + (\delta \mathcal{E})_x = 0, \]

with \( \mathcal{E} = -2 \xi F(\rho) + \frac{\xi^2}{2 \rho} \) and \( \delta \mathcal{E} = \mathcal{E}_\rho - \partial_x \mathcal{E}_\rho_x \). Benzoni-Gavage et al. proved that weak hyperbolicity of the Whitham modulation equations associated with the Euler–Korteweg system is a necessary condition for spectral stability \(^{42}\), Theorem 1. We distinguish our method from Refs. 30, 42 by not recasting Equation (1) as either the hydrodynamic system in Equations (2) and (3) nor as the Euler–Korteweg system in Equations (4) and (5), but instead we directly compute the polynomial whose roots are the characteristics of the linearized Whitham modulation equations.

The main result of this paper, Theorem 3, shows that the Whitham modulation theory for Equation (1) correctly predicts the rigorous spectral stability results contained in Ref. 1. Leisman et al. relate spectral instability of periodic travelling wave solutions of Equation (1) near the origin of the spectral plane to the breakup of the generalized kernel of the operator of the linearized problem. The authors express the genericity conditions on the Jordan chains of the linearized operator in terms of matrices whose entries are moments of the travelling wave solutions. They use these matrices to derive a normal form for the spectrum of the linearized operator at the origin subject to both longitudinal and transverse perturbations. We give a brief summary of their results, before applying Whitham’s averaged Lagrangian method to derive the Whitham modulation equations. We use the genericity conditions given in Ref. 1 to homogenize the modulation equations, turning them into a quasi-linear system of four equations in four slowly modulated parameters of the travelling wave solutions. The characteristics of this system are the zeros of a quartic equation, which, upon changing variables, we identify as the normal form for the four continuous bands of spectrum emerging from the origin.

We have organized this paper into two main sections. In Section 2, we introduce the relevant spectral stability results of Ref. 1, leading to a rigorous criterion for modulational instability in Corollary 1. We begin Section 3 with a general overview of Whitham’s averaged Lagrangian approach to deriving the modulation equations. We then apply this theory to Equation (1) in Section 3.1, from which we conclude in Corollary 2 that the Whitham theory criterion for modulational instability agrees exactly with the rigorous spectral analysis of Section 2. We conclude the paper with a discussion in Section 4 as well as, to the best of our knowledge, several open problems in the area. We include some necessary though long calculations, as well as, we hope, some useful identities in Appendices A–F.

## 2 MODULATIONAL STABILITY FROM THE LINEAR THEORY

In this section, we follow the analysis of the modulational stability problem contained in Ref. 1. We seek travelling wave solutions of Equation (1) in the form

\[ \psi(x, t) = e^{i \omega t} \phi(x + ct). \]
Writing \( y = x + ct \), we express \( \phi \) in polar coordinates

\[
\phi(y) = \exp \left( i \left( \theta_0 + \frac{cy}{2} + S(y + y_0) \right) \right) A(y + y_0).
\]  

(6)

Substituting Equation (6) into Equation (1) and equating real and imaginary parts, we have

\[
2A_y S_y + AS_{yy} = 0
\]

(7)

\[
A_{yy} = -\left( \omega + \frac{c^2}{4} \right) A + AS_y^2 - \zeta f(A^2) A.
\]

(8)

Integrating Equation (7) yields

\[
S_y = \frac{\kappa}{A^2},
\]

(9)

which can be substituted into Equation (8) and upon integrating we have

\[
A_y^2 = 2E - \left( \omega + \frac{c^2}{4} \right) A^2 - \frac{\kappa^2}{A^2} - \zeta F(A^2).
\]

(10)

The symmetries of Equation (1) allow us to eliminate several of the seven parameters \( E, \omega, c, \kappa, \zeta, y_0, \theta_0 \). In particular, Equation (1) is invariant under the transformations (assume \( \alpha \in \mathbb{R} \)):

- \( \psi(x, t) \mapsto \psi(x, t)e^{i\alpha} \) (phase invariance);
- \( \psi(x, t) \mapsto \psi(x + \alpha, t) \) (translation invariance);
- \( \psi(x, t) \mapsto \psi(x + \alpha t, t)e^{-i \left( \frac{\alpha}{2} x + \frac{\alpha^2}{4} t \right)} \) (Galilean invariance).

Phase and translation invariance means that we can eliminate \( \theta_0 \) and \( y_0 \) from Equation (6). Furthermore, by Galilean invariance, we can reduce \( \psi \) to

\[
\psi(x, t) = e^{i \left( \omega + \frac{c^2}{4} \right) t} e^{iS(x)} A(x).
\]

(11)

Both Equation (11) and Equation (10) suggest that we can absorb \( \frac{c^2}{4} \) into \( \omega \) (or equivalently set \( c = 0 \)), eliminating \( c \) from the equations. This leads us to make the following definition about the parameter space \( \Omega \):

**Definition 1.** We define the parameter domain \( \Omega \) as the open set of parameter values \((E, \kappa, \omega, \zeta)\) such that:

- \( \kappa > 0; \)
- The function \( P(A) = 2E - \omega A^2 - \frac{\kappa^2}{A^2} - \zeta F(A^2) \) has two positive, real, simple roots \( a_-, a_+ \) with \( a_- < a_+ \) and \( P(A) \) is real and positive for \( A \in (a_-, a_+) \).
As explained in [Ref. 1, Remark 1], parameter values in $\Omega$ represent the most generic case and allow us to freely differentiate with respect to the parameters. The cases where $\kappa = 0$ or $R(A)$ has higher order roots correspond to degenerate cases that require their own analyses. We assume henceforth that our parameters are taking values in $\Omega$.

We are interested in periodic solutions $A$ to Equations (9) and (10). We make the assumption $A(0) = a_-, A(T^*_+ = a_+)$, which we can always guarantee by translating the wave. Under these conditions, the function $\phi$ has the quasi-periodic boundary conditions:

$$\phi(T_*) = \phi(0)e^{i\eta}$$

$$\phi_y(T_*) = \phi_y(0)e^{i\eta},$$

where the period $T_*$ and the quasi-momentum $\eta = S(T_*) - S(0)$ are functions of the parameters $E, \kappa, \omega, \zeta$. These quantities, and the mass $M$, can be expressed as derivatives of the classical action:

$$K(E, \kappa, \omega, \zeta) = \int_0^{T_*)} A_y^2 dy = 2 \int_{a_-}^{a_+} \frac{1}{A^2} \sqrt{2E - \omega A^2 - \frac{\kappa^2}{A^2} - \zeta F(A^2)} dA. \quad (14)$$

In particular, we have

$$T_*(E, \kappa, \omega, \zeta) = 2 \int_{a_-}^{a_+} \frac{1}{A_y} dA = 2 \int_{a_-}^{a_+} \frac{1}{\sqrt{2E - \omega A^2 - \frac{\kappa^2}{A^2} - \zeta F(A^2)}} dA$$

$$= \frac{\partial K}{\partial E} \quad (15)$$

$$\eta(E, \kappa, \omega, \zeta) = S(T_*) - S(0) = 2 \int_{a_-}^{a_+} \frac{\kappa}{A^2 A_y} dA$$

$$= 2 \int_{a_-}^{a_+} \frac{\kappa}{A^2} \sqrt{2E - \omega A^2 - \frac{\kappa^2}{A^2} - \zeta F(A^2)} dA$$

$$= -\frac{\partial K}{\partial \kappa} \quad (16)$$

$$M(E, \kappa, \omega, \zeta) = 2 \int_{a_-}^{a_+} \frac{A^2}{A_y} dA = 2 \int_{a_-}^{a_+} \frac{A^2}{\sqrt{2E - \omega A^2 - \frac{\kappa^2}{A^2} - \zeta F(A^2)}} dA$$

$$= -2 \frac{\partial K}{\partial \omega} \quad (17)$$

We now consider the linearized problem under the perturbation:

$$\psi(y, t) = e^{i\omega t} \left( \phi(y) + \epsilon e^{i[S(y+y_0)+\frac{\zeta y}{2}+\theta_0]} W(y, t) \right).$$
Since the phase $\exp(i[S(y + y_0) + \frac{cy}{2} + \theta_0])$ is also present in $\phi(y)$ (Equation (6)), then we can consider $W$ as a complex-valued perturbation of $A$. At $O(\varepsilon)$, we have:

$$iW_t = W_{yy} + \omega W - S_y^2 W + \xi f(A^2)W + 2\xi f'(A^2)A^2 \text{Re}(W) + i(S_{yy}W + 2S_yW_y). \quad (18)$$

Writing $W(y, t) = u(y, t) + iv(y, t)$ in Equation (18), we have the two linearized equations

$$u_t = u_{yy} + \omega v - S_y^2 v + \xi f(A^2)v + S_{yy}u + 2S_yu_y$$
$$-v_t = u_{yy} + \omega u - S_y^2 u + \xi f(A^2)u + 2\xi f'(A^2)A^2u - S_{yy}v - 2S_yv_y,$$

which can be collected into the equation

$$
\begin{pmatrix}
  u \\
  v
\end{pmatrix}_t =
\begin{pmatrix}
  \mathcal{K} & -\mathcal{L}_- \\
  \mathcal{L}_+ & \mathcal{K}
\end{pmatrix}
\begin{pmatrix}
  u \\
  v
\end{pmatrix},
$$

(19)

where

$$\mathcal{K} = S_{yy} + 2S_y \partial_y$$
$$\mathcal{L}_+ = -\omega - \partial_{yy} + S_y^2 - \xi f(A^2) - 2\xi f'(A^2)A^2$$
$$\mathcal{L}_- = -\omega - \partial_{yy} + S_y^2 - \xi f(A^2).$$

We can further manipulate Equation (19):

$$
\begin{pmatrix}
  u \\
  v
\end{pmatrix}_t =
\begin{pmatrix}
  0 & -1 \\
  1 & 0
\end{pmatrix}
\begin{pmatrix}
  \mathcal{L}_+ \mathcal{K} \\
  \mathcal{K}^T \mathcal{L}_-
\end{pmatrix}
\begin{pmatrix}
  u \\
  v
\end{pmatrix}
\quad (20)
= \mathcal{L}
\begin{pmatrix}
  u \\
  v
\end{pmatrix}.
$$

(21)

Since $\mathcal{L}$ is the product of a skew-symmetric operator and symmetric operator, then Equation (21) defines a Hamiltonian eigenvalue problem. From here, the idea is to analyze the Jordan chains of $\mathcal{L}$. In particular, we wish to find the genericity conditions on the Jordan structure of the linearized operator in terms of the derivatives of $K$. Having found these conditions, we can then perturb $\mathcal{L}$ and analyze the affect this has on the generalized kernels. The following result summarizes the genericity conditions.

**Theorem 1.** Assume that:

- $(E, k, \omega, \xi) \in \Omega$;
- $F(x)$ is linearly independent from $1, x, \frac{1}{x}$;
- $A(y)$ is nonconstant.
The generalized kernel of $\mathcal{L}$ (defined in Equation (21)) generically takes the form of a direct sum of two Jordan chains of length two. Making the definitions

$$\sigma := \{T_*, \eta\}_E = T_\ast \eta - T_\ast \eta_E$$

$$D := \begin{vmatrix}
K_{\eta \eta} & K_{\eta E} & K_{\eta \omega} & T_* \\
K_{\eta E} & K_{EE} & K_{E \omega} & 0 \\
K_{\eta \omega} & K_{E \omega} & K_{\omega \omega} & 0 \\
T_* & 0 & 0 & -M
\end{vmatrix},$$

then the genericity conditions on these Jordan chains are:

$$\sigma \neq 0 \quad (22)$$

$$D \neq 0. \quad (23)$$

Remark 1. We have chosen to omit several results from Theorem 1 given in Ref. 1, such as the explicit calculation of the Jordan chains of $\mathcal{L}$. This is because the Whitham theory in the later sections of this paper makes use of just the genericity conditions on these chains.

Remark 2. In the proof of Theorem 1, the authors calculate the determinant $D$ in terms of $T_\ast, M, \eta$ and the Poisson bracket quantities defined in Appendix A. Using the Dodgson–Jacobi–Desnanot condensation identity, they calculate:

$$-\frac{\sigma^3}{4}D = \begin{vmatrix}
a_2 & b_2 \\
b_2 & d_2
\end{vmatrix},$$

where $a_2, b_2, d_2$ are defined in Appendix A.

We now examine the breakup of the Jordan chains of $\mathcal{L}$ under perturbations of the quasi-periodic boundary conditions. We start with the following proposition:

**Proposition 1**. Let $\mathcal{L}$ be an operator with compact resolvent. Suppose further that $\mathcal{L}$ has a $d$-dimensional kernel spanned by $\{u_{2j}\}_{j=0}^{d-1}$ and a $d$-dimensional first generalized kernel spanned by $\{u_{2j+1}\}_{j=0}^{d-1}$ satisfying $\mathcal{L}u_{2j+1} = u_{2j}$. Suppose similarly that $\mathcal{L}$ has a left basis satisfying $v_{2j+1}\mathcal{L} = 0, v_{2j} = v_{2j+1}$. Consider a perturbation of the form $\mathcal{L} + \mu \mathcal{L}^{(1)} + \mu^2 \mathcal{L}^{(2)}$, where $\mathcal{L}^{(1)}(\lambda - \mathcal{L})^{-1}, \mathcal{L}^{(1)}(\lambda - \mathcal{L}^{(1)})^{-1} \mathcal{L}^{(1)}$ and $\mathcal{L}^{(2)}$ are bounded operators. Suppose that the first-order perturbation satisfies the conditions:

$$v_{2j+1}\mathcal{L}^{(1)}u_{2k} = 0 \quad \forall j, k = 0, ..., d - 1.$$

Then, to leading order in $\mu$, the $2d$-dimensional generalized kernel breaks up into $2d$ eigenspaces, with the eigenvalues given by

$$\lambda(\mu) = \lambda_1 \mu + O(\mu^2),$$
where $\lambda_1$ is a root of the polynomial

$$\text{det}(\lambda_1^2 M^{(2)} + \lambda_1 M^{(1)} + M^{(0)}) = 0,$$

with the $d \times d$ matrices $M^{(i)}$ are defined as

$$M^{(2)}_{j,k} = v_{2j+1}u_{2k+1},$$

$$M^{(1)}_{j,k} = -v_{2j}L^{(1)}u_{2k} - v_{2j+1}L^{(1)}u_{2k+1},$$

$$M^{(0)}_{j,k} = v_{2j+1}L^{(1)}L^{-1}L^{(1)}u_{2k} - v_{2j+1}L^{(2)}u_{2k}.$$

Proposition 1 allows us to relate the eigenvalues $\lambda$ near the origin to the break up of the generalized kernels of $L$ under small perturbations. We deal with the case of longitudinal perturbations, that is, the 1D NLS Equation (1). In particular, when we substitute

$$\begin{pmatrix} u \\ v \end{pmatrix} = e^{it}u(y)$$

into the linearized problem Equation (21), we have

$$Lu = \lambda u. \quad (24)$$

Equation (24) can be written as a system of four first-order ODEs in $y$ with $T_\ast$-periodic coefficients, and so by applying Floquet theory we see that the spectrum of $L$ is the union over all $\mu \in (-\frac{\pi}{T_\ast}, \frac{\pi}{T_\ast}]$ of the spectrum of $L$ with quasi-periodic boundary conditions:

$$u(T_\ast) = e^{i\mu T_\ast}u(0)$$

$$u_y(T_\ast) = e^{i\mu T_\ast}u_y(0).$$

If instead we write $u = e^{i\mu y}v$, then $v$ has periodic boundary conditions, and the $\mu$-dependency is instead captured by a $\mu$-dependent operator:

$$L(\mu)v = \lambda v$$

$$L(\mu) := L + 2i\mu \begin{pmatrix} S_y & \partial_y \\ -\partial_y & S_y \end{pmatrix} + \mu^2 \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Taking

$$L^{(1)} = 2i \begin{pmatrix} S_y & \partial_y \\ -\partial_y & S_y \end{pmatrix}$$

$$L^{(2)} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

allows us to apply Proposition 1, leading to the following theorem.
**Theorem 2** Corollary 1. Suppose that \( \mathcal{L} \) is defined as in Equation (21), and further suppose that the genericity conditions of Theorem 1 apply. For small values of the Floquet exponent \( \mu \), the normal form for the four continuous bands of spectrum emerging from the origin in the spectral plane is

\[
\det \left( \begin{pmatrix} a_2 & b_2 \\ b_2 & d_2 \end{pmatrix} \right) + \lambda \mu \begin{pmatrix} a_1 & b_1 \\ b_1 & d_1 \end{pmatrix} + \mu^2 \begin{pmatrix} a_0 & b_0 \\ b_0 & d_0 \end{pmatrix} + O(5) = 0, \tag{25}
\]

where \( O(5) \) consists of terms \( \lambda^i \mu^j \) with \( i, j > 0 \) and \( i + j \geq 5 \). The matrix entries are given in Appendix A.

**Corollary 1** (Modulational instability criterion). If any of the roots \( \lambda \) of Equation (25) are not purely imaginary, then the travelling wave \( \phi \) about which we have linearized is modulationally unstable.

## 3 WHITHAM MODULATION THEORY

Our goal in this section is to provide a formal Whitham theory calculation that results in the same criterion for modulational instability as the rigorous results in the previous section, in particular Theorem 2 and Corollary 1. We want to show that the equation for the characteristics of the Whitham modulation equations is equivalent to the normal form Equation (25). There are several ways to derive the Whitham modulation equations; we choose to use the averaged Lagrangian formulation and the variational principle from Whitham’s work,23,25,26 since the averaged Lagrangian closely resembles the classical action \( K \) (cf. Equation (14)) from the rigorous linear theory.

As a side note, many of the symbols of the previous section will be re-used but with the subscript \( * \). These subscripted symbols are seen as completely new, and not connected to their un-subscripted counterparts. We start with the Lagrangian of Equation (1):

\[
L(\psi_t, \psi_x, \bar{\psi}_t, \bar{\psi}_x, \psi) = i(\psi \bar{\psi}_t - \psi_t \bar{\psi}) + 2|\psi_x|^2 - 2\zeta F(|\psi|^2), \tag{26}
\]

which satisfies the Euler–Lagrange equations:

\[
\begin{align*}
L_\psi - \partial_t L_{\psi_t} - \partial_x L_{\psi_x} &= 0 \\
L_{\bar{\psi}} - \partial_t L_{\bar{\psi}_t} - \partial_x L_{\bar{\psi}_x} &= 0.
\end{align*}
\]

We seek solutions to Equation (1) of the form:

\[
\psi(x,t) = r(x,t) e^{i\varphi(x,t)}.
\]

Upon substitution, we have (for imaginary and real parts, respectively)

\[
\begin{align*}
r_t &= 2\varphi_x r_x + \varphi_{xx} r \\
-\varphi_t r &= r_{xx} - \varphi_x^2 r + \zeta f(r^2) r.
\end{align*}
\]
with the Lagrangian:

\[
L(r_x, r, \varphi_t, \varphi_x) = -2\varphi_t r^2 + 2(r_x)^2 + 2(\varphi_x)^2 r^2 - 2\xi F(r^2). \tag{29}
\]

We now seek (quasi)periodic solutions \(r, \varphi\), with period normalized to \(2\pi\). Introducing the variable \(\vartheta = kx - \omega_* t\), we let

\[
\begin{align*}
    r(x, t) &= R(\vartheta) \\
    \varphi(x, t) &= \beta x - \gamma_* t + \Phi(\vartheta).
\end{align*}
\]

The pseudo-phase component \(\beta x - \gamma_* t\) is a necessary generalization since only the derivatives of \(\varphi\) appear in \(L\) (cf. Equation (29)). Consequently, the pseudo-phase ensures that the quantities \(\varphi_x\) and \(\varphi_t\) have mean \(\beta\) and \(-\gamma_*\), respectively, when averaged over one period. This is reminiscent of the quasi-periodic boundary conditions set for \(\psi\) in Equation (12). Substituting into Equations (27)–(29) yields

\[
-\omega_* R_\vartheta = 2kR_\vartheta (\beta + k\Phi_\vartheta) + k^2 \Phi_{\vartheta\vartheta} R \tag{30}
\]

\[
R(\gamma_* + \omega_* \Phi_\vartheta) = k^2 R_{\vartheta\vartheta} - R(\beta + k\Phi_\vartheta)^2 + \xi f(R^2) R \tag{31}
\]

\[
L(kR_\vartheta, R, -\gamma - \omega_* \Phi_\vartheta, \beta + k\Phi_\vartheta) = 2R^2(\gamma_* + \omega_* \Phi_\vartheta) + 2k^2 R^2 - 2\xi F(R^2). \tag{32}
\]

For a slow modulation, we consider the parameters \(\omega_*\), \(k\), \(\gamma_*\), \(\beta\) to be functions of \(X = \varepsilon x\) and \(T = \varepsilon t\). We write

\[
\vartheta = \varepsilon^{-1}\Theta(X, T), \quad \beta x - \gamma_* t = \bar{\vartheta} = \varepsilon^{-1}\bar{\Theta}(X, T),
\]

and define

\[
-\omega_*(X, T) = \Theta_T, \quad k(X, T) = \Theta_X, \quad -\gamma_*(X, T) = \bar{\Theta}_T, \quad \beta(X, T) = \bar{\Theta}_X. \tag{34}
\]

Our functions \(R\) and \(\Phi\) are also written in these variables as

\[
R = R(\vartheta, X, T; \varepsilon), \quad \Phi = \Phi(\vartheta, X, T; \varepsilon).
\]

The fact that these functions are evolving on both slow and fast scales is called two-timing, and is closely examined in Refs. 25, 26. When averaging the Lagrangian, we consider \(R\) and \(\Phi\) to be functions of three independent variables \(\vartheta, X, T\), even though \(\vartheta\) is a function of \(X\) and \(T\) in Equation (33). This extra flexibility ensures that secular terms in the asymptotic expansions are suppressed, and in conjunction with the variational principle this is equivalent to a WKB approximation.26

According to Whitham’s theory,25,26 the leading order modulation equations can be derived from the variational principle:

\[
\delta V(R_\vartheta, R, \Phi_\vartheta, \Theta, \bar{\Theta}) = \delta \int \int \frac{1}{2\pi} \int_0^{2\pi} L(kR_\vartheta, R, -\gamma_* - \omega_* \Phi_\vartheta, \beta + k\Phi_\vartheta)d\vartheta dXdT = 0. \tag{35}
\]
For functions \( h \) that vanish on the \((\theta, X, T)\) boundary, Equation (35) means that for variations in \( R \), we have

\[
V(R_0 + h\theta, R + h, \Phi_\theta, \Theta) - V(R_0, R, \Phi_\theta, \Theta) = 0
\]

\[
\Rightarrow \int \int \int_{0}^{2\pi} h\theta L_{R\theta} + hL_R + O(h^2)d\theta dX dT = 0.
\]

Integrating by parts, we end up with

\[
\int \int \int_{0}^{2\pi} h(L_R - \partial_\theta L_{R\theta})d\theta dX dT = 0.
\]

Since this is true for all such \( h \), we conclude that:

\[
\partial_\theta L_{R\theta} - L_R = 0. \tag{36}
\]

Equation (36) is simply Equation (31), one of the Euler-Lagrange equations for \( L \) (cf. Equation (32)). The other Euler–Lagrange equation comes from considering variations in \( \Phi \), which yields

\[
\partial_\theta L_{\Phi_\theta} = 0. \tag{37}
\]

Equation (37) has an immediate first integral:

\[
B(X, T) = L_{\Phi_\theta}, \tag{38}
\]

so \( B \) is constant with respect to \( \theta \), however, it is now added to the ensemble of slowly varying parameters. Equation (37) is in fact a multiple of Equation (30) (the factor is \( 4R \)), so finding \( B \) is equivalent to finding a first integral of Equation (30). Equation (36) also admits an integral, since this equation is an ODE in the variable \( \theta \). To see this, we multiply Equation (36) by \( R_\theta \):

\[
R_\theta \partial_\theta L_{R\theta} - R_\theta L_R = 0
\]

\[
\Rightarrow \partial_\theta(R_\theta L_{R\theta}) - R_\theta \partial_\theta L_{R\theta} - R_\theta L_R = 0
\]

\[
\Rightarrow \partial_\theta(R_\theta L_{R\theta}) - \partial_\theta L + B\Phi_{\theta\theta} = 0.
\]

Note that we have used Equation (37) to write the \( \theta \)-derivative of \( L \) as

\[
\partial_\theta L = R_{\theta\theta} L_{R\theta} + R_\theta L_R + B\Phi_{\theta\theta}.
\]

Integrating, we have

\[
R_\theta L_{R\theta} + B\Phi_{\theta} - L = A_\theta(X, T), \tag{39}
\]
for a slowly varying parameter $A_*$. For variations in $\Theta$, we consider $\Theta(X, T) + h(X, T)$ for an appropriate function $h$ vanishing on the $(X, T)$ boundary. This means that $k$ will be replaced by $k + h_X$, and similarly $\omega_*$ by $\omega_* - h_T$. Writing the averaged Lagrangian as

$$\bar{L}(\omega_*, k, \gamma_*, \beta) = \frac{1}{2\pi} \int_0^{2\pi} L d\theta,$$  (40)

we have

$$V(R_\beta, R, \Phi_\beta, \theta + h, \bar{\Theta}) - V(R_\beta, R, \Phi_\beta, \theta, \bar{\Theta}) = 0$$

$$\Rightarrow \int \int \bar{L}(\omega_* - h_T, k + h_X, \gamma_*, \beta) - \bar{L}(\omega_*, k, \gamma_*, \beta) dX dT = 0,$$

and hence

$$\int \int h_N \bar{L}_k - h_T \bar{L}_{\omega_*} + O(h^2) dX dT = 0.$$  (41)

From Equation (41), we have

$$\int \int h(\partial_T \bar{L}_{\omega_*} - \partial_X \bar{L}_k) dX dT = 0,$$

which is true for all such $h$, and so we conclude that

$$\partial_T \bar{L}_{\omega_*} - \partial_X \bar{L}_k = 0.$$  (42)

Equation (42) is called a modulation equation since the quantities involved are functions of the slowly modulated variables $X$ and $T$. Similarly for variations in $\bar{\Theta}$, we have another modulation equation:

$$\partial_T \bar{L}_{\gamma_*} - \partial_X \bar{L}_{\beta} = 0.$$  (43)

The last two modulation equations are associated with the conservation of waves:

$$\partial_T k + \partial_X \omega_* = 0$$  (44)

$$\partial_T \beta + \partial_X \gamma_* = 0,$$  (45)

which is a consequence of requiring the mixed partial derivatives of $\Theta(X, T)$ and $\bar{\Theta}(X, T)$ to be equal. At this point, we have derived four modulation equations in the four parameters $(\omega_*, k, \gamma_*, \beta)$. In order to evaluate the averaged Lagrangian Equation (40), we need to solve Equations (38) and (39) for $R, \Phi$. Instead, Whitham proposes using the first integrals $A_*(X, T)$ and $B_*(X, T)$ to simplify the form of the averaged Lagrangian. We can avoid directly computing $R, \Phi$, and moreover we can absorb the dispersion relations into one variational principle. To this end,
we consider a Hamiltonian transformation with the variables:

\[ \Pi_1 = L_\theta, \quad \Pi_2 = L_{\Phi \theta} = B. \]  

These are generalized momenta, and so we apply a Legendre transform to \( L \) in order to eliminate \( R_\theta \) and \( \Phi_\theta \) from the equations:

\[ H(\Pi_1, \Pi_2, R, \Phi; \omega_*, k, \gamma_*, \beta) = R_\theta \Pi_1 + \Phi_\theta \Pi_2 - L. \]  

We see from the transformation that

\[ R_\theta = \partial_{\Pi_1} H, \quad \Phi_\theta = \partial_{\Pi_2} H, \]  

and it follows from Equation (36) and Equation (37), respectively, that

\[ \partial_\theta \Pi_1 = -\partial_R H, \quad \partial_\theta \Pi_2 = -\partial_\Phi H = 0. \]  

Equations (48) and (49) are Hamilton's equations. We can now write the earlier variational principle Equation (35) as

\[ \delta \int \int \overline{L} dX dT = 0, \]  

where

\[ \overline{L} = \frac{1}{2\pi} \int_{0}^{2\pi} (R_\theta \Pi_1 + B \Phi_\theta - H) d\theta \]  

\[ = \frac{1}{2\pi} \int_{0}^{2\pi} (R_\theta \Pi_1 - H) d\theta, \]  

since \( \Phi \) is \( 2\pi \)-periodic. The averaged Lagrangian is now a function of \( H, B \), and the previous four parameters. We note that Hamilton's Equations (48) and (49) follow from the independent variations of \( \Pi_1, R, \Pi_2, \Phi \) in Equation (51). We use this extension as Whitham describes in Refs. 25, 26. Next, we observe that Equation (47) is the same as Equation (39), so we identify

\[ H(\Pi_1, \Pi_2, R; \omega_*, k, \gamma_*, \beta) = A_*(X, T). \]  

The stationary values of Equation (51) also satisfy Equation (53), meaning that we can restrict the stationary values of Equation (51) to the class of functions \( R, \Phi, \Pi_1, \Pi_2 \) that satisfy Equation (53). Importantly, this is the only restriction we make; using the dispersion relation or any information about the forms of the solutions \( \Pi_1 \) and \( R_\theta \) (Equation (48)) would result in \( \overline{L} \) having no variation. We relabel \( H(\Pi_1, \Pi_2, R; \omega_*, k, \gamma_*, \beta) \) as \( H(X, T) \) in Equation (51), and we solve Equation (53) for \( \Pi_1(R; H, \omega_*, k, B, \gamma_*, \beta) \) which yields

\[ \mathcal{L}(H, \omega_*, k, B, \gamma_*, \beta) = \frac{1}{2\pi} \int \Pi_1 dR - H, \]
where the integral is taken around the orbit of $R$. The variational principle Equation (50) can now be written as

$$
\delta \int \int \mathcal{L}(H, \omega, k, B, \gamma, \beta) dX dT = 0.
$$

(55)

As mentioned earlier, we have now added the two parameters $H$ and $B$, however, we have exchanged the variational Equations (48) and (49) for variations in $H$ and $B$:

$$
\mathcal{L}_H = 0
$$

(56)

$$
\mathcal{L}_B = 0.
$$

(57)

Equations (56) and (57) are relations between the parameters of the periodic wavetrain, and so they are in fact the dispersion relations. Our aim is to use these equations in order to eliminate two of the six parameters from the four modulation equations, resulting in a homogeneous system of first-order PDEs. Using Equations (55), (44), and (45), we now have a complete picture of the Whitham theory:

$$
\partial_T \mathcal{L}_\omega - \partial_X \mathcal{L}_k = 0
$$

(58)

$$
\partial_T \mathcal{L}_\gamma - \partial_X \mathcal{L}_\beta = 0
$$

(59)

$$
\partial_T k + \partial_X \omega = 0
$$

(60)

$$
\partial_T \beta + \partial_X \gamma = 0.
$$

(61)

3.1 Whitham theory applied to NLS

In this subsection, we apply the more general theory and observations from Section 3 to Equation (1). We provide a direct computation of the characteristics of the Whitham modulation equations, from which we conclude that the modulational instability criterion from the Whitham theory agrees with the spectral analysis in Section 2. For the sake of brevity, we include more detailed calculations in Appendices B–F.

We calculate $\mathcal{L}$ in terms of the parameters $H, \omega, k, B, \gamma, \beta$ using Equations (30)–(32). First, $\Pi_2 = B$ amounts to taking an integral of Equation (30), which yields

$$
B = 2\omega R^2 + 4k R^2 (\beta + k \Phi_0).
$$

(62)

Next, we calculate $H$ using Equation (47), eliminating $\Phi_0$ and $R_0$ via Equation (62) and $\Pi_1 = L_{R_0} = 4k^2 R_0$:

$$
H = \frac{\Pi_1^2}{4k^2} + B\Phi_0 - \frac{\Pi_1^2}{8k^2} - 2R^2(\gamma_0 + \omega \Phi_0) - 2R^2(\beta + k \Phi_0)^2 + 2\zeta F(R^2)
$$
\[
\Pi_1^2 = \frac{\beta B}{k} - \frac{\omega_s B}{2k^2} + 2R^2\left(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s\right) + \frac{B^2}{8k^2R^2} + 2\zeta F(R^2)
\]

\[
\Rightarrow \frac{\Pi_1^2}{8k^2} = H + \frac{\beta B}{k} + \frac{\omega_s B}{2k^2} - 2R^2\left(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s\right) - \frac{B^2}{8k^2R^2} - 2\zeta F(R^2).
\]

This can also be written as

\[
2k^2R_\theta^2 = H + \frac{\beta B}{k} + \frac{\omega_s B}{2k^2} - 2R^2\left(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s\right) - \frac{B^2}{8k^2R^2} - 2\zeta F(R^2), \tag{63}
\]

which we identify as the first integral of Equation (31) once \(\Phi_\theta\) has been eliminated, that is,

\[
k^2R_{\theta\theta} = -R\left(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s\right) + \frac{B^2}{16k^2R^3} - \zeta f(R^2)R. \tag{64}
\]

The averaged Lagrangian is hence

\[
\mathcal{L} = k\sqrt{2} \frac{\sqrt{2}}{\pi} \int \sqrt{H + \frac{\beta B}{k} + \frac{\omega_s B}{2k^2} - 2R^2\left(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s\right) - \frac{B^2}{8k^2R^2} - 2\zeta F(R^2)}dR - H. \tag{65}
\]

Following Whitham’s examples\(^{22,26}\), we introduce a function \(W\) that is essentially the classical action:

\[
W(H, \omega_s, k, B, \gamma_s, \beta) = \frac{1}{\pi} \int \frac{\Pi_1}{2k}dR \tag{66}
\]

\[
= \frac{\sqrt{2}}{2\pi} \int \sqrt{H + \frac{\beta B}{k} + \frac{\omega_s B}{2k^2} - 2R^2\left(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s\right) - \frac{B^2}{8k^2R^2} - 2\zeta F(R^2)}dR. \tag{67}
\]

This allows us to write Equation (65) as:

\[
\mathcal{L} = 2kW - H. \tag{68}
\]

For a generic evaluation of \(W\) from Equation (67), we require assumptions similar to those listed in Definition 1. We derive these assumptions by equating our periodic solution \(\psi(x, t) = R(\theta)\exp(i(\beta x - \gamma_s t + \Phi(\theta)))\) with the periodic solution Equation (6), which yields (once translation invariance and phase invariance are taken into account):

\[
R(\theta) = A(y) \tag{69}
\]

\[
\beta x - \gamma_s t + \Phi(\theta) = \left(\omega - \frac{c^2}{4}\right)t + \frac{cy}{2} + S(y). \tag{70}
\]
Note that we have redefined $\omega$ as $\omega - \frac{c^2}{4}$ as suggested by Equation (11). Taking $x$ and $t$ derivatives of Equation (69), we have

$$kR_\theta = A_y, \quad -\omega_s R_\theta = c A_y$$

$$\Rightarrow c = -\frac{\omega_s}{k}.$$  \hfill (72)

Similarly for Equation (70), we have

$$\beta + k \Phi_\theta = \frac{c}{2} + S_y, \quad -\gamma_s - \omega_s \Phi_\theta = \omega - \frac{c^2}{4} + \frac{c^2}{2} + c S_y$$

$$\Rightarrow \omega = \frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s.$$  \hfill (74)

Substituting Equations (71) to (73) into Equation (9) yields

$$\beta + \frac{\omega_s}{2k} + k \Phi_\theta = \frac{\kappa}{R^2},$$

and recalling Equation (62), we identify

$$\kappa = \frac{B}{4k}.$$  \hfill (75)

Finally, using Equations (69), (71), (72), (74), and (75), we see that Equation (63) is twice Equation (10), with

$$E = \frac{1}{4} \left( H + \frac{\beta B}{k} + \frac{\omega_s B}{2k^2} \right).$$  \hfill (76)

Equations (72) and (74)–(76) now express the parameters of the linear theory in terms of our Whitham parameters. Recalling Definition 1, we have that the parameters $(H, \omega_s, k, B, \gamma_s, \beta)$ exist such that:

- $\frac{B}{k} > 0$;
- The function $P(R) = H + \frac{\beta B}{k} + \frac{\omega_s B}{2k^2} - 2R^2(\frac{\beta \omega_s}{k} + \frac{\omega_s^2}{4k^2} - \gamma_s) - \frac{B^2}{8k^2R^2} - 2\xi F(R^2)$ has two positive, real, simple roots $R_- = a_-$ and $R_+ = a_+$, with $R_- < R_+$ and $P(R)$ real and positive for $R \in (R_-, R_+)$.  

We make the change of variables:

$$U = \frac{\omega_s}{k},$$

$$J = \frac{B}{k}.$$
This eliminates the explicit dependence of $P(R)$ on $k$, which will be advantageous when we calculate the characteristics of the modulation equations. Also note that the two roots $R_-, R_+$ are now functions of $H, U, J, \gamma_*, \beta, \zeta$. Updating $W$ in Equation (67), we have

$$W(H, U, J, \gamma_*, \beta, \zeta) = \frac{\sqrt{2}}{\pi} \int_{R_-}^{R_+} \sqrt{H + \beta J + \frac{UJ}{2} - 2R^2\left(\beta U + \frac{U^2}{4} - \gamma_*\right) - \frac{J^2}{8R^2} - 2\xi F(R^2)}dR. \quad (77)$$

Moreover, we can relate the classical action from Equation (14) with $W$:

$$K = \pi W. \quad (78)$$

We now calculate the derivatives of $W$ with respect to the parameters:

$$W_H = \frac{\sqrt{2}}{\pi} \int_{R_-}^{R_+} \frac{1}{2\sqrt{H + \beta J + \frac{UJ}{2} - 2R^2\left(\beta U + \frac{U^2}{4} - \gamma_*\right) - \frac{J^2}{8R^2} - 2\xi F(R^2)}}dR \quad (79)$$

$$W_J = W_H \left(\beta + \frac{U}{2}\right) - \eta_* \quad (80)$$

$$\eta_* := \frac{\sqrt{2}}{\pi} \int_{R_-}^{R_+} \frac{J}{8R^2\sqrt{H + \beta J + \frac{UJ}{2} - 2R^2\left(\beta U + \frac{U^2}{4} - \gamma_*\right) - \frac{J^2}{8R^2} - 2\xi F(R^2)}}dR \quad (81)$$

$$M_* := W_{\gamma_*} = \frac{\sqrt{2}}{\pi} \int_{R_-}^{R_+} \frac{R^2}{\sqrt{H + \beta J + \frac{UJ}{2} - 2R^2\left(\beta U + \frac{U^2}{4} - \gamma_*\right) - \frac{J^2}{8R^2} - 2\xi F(R^2)}}dR \quad (82)$$

$$W_U = \frac{J}{2}W_H - M_* \left(\beta + \frac{U}{2}\right) \quad (83)$$

$$W_\beta = JW_H - UM_* \quad (84)$$

$$W_\zeta = -\frac{\sqrt{2}}{\pi} \int_{R_-}^{R_+} \frac{F(R^2)}{\sqrt{H + \beta J + \frac{UJ}{2} - 2R^2\left(\beta U + \frac{U^2}{4} - \gamma_*\right) - \frac{J^2}{8R^2} - 2\xi F(R^2)}}dR. \quad (85)$$

We choose the notation $\eta_*$ and $M_*$ because these integrals are closely related to the $\eta$ and $M$ from the linear theory. We give the relations in Appendix B. Using Equation (68), we have:

$$\mathcal{L}_{\omega_*} = 2W_U$$

$$\mathcal{L}_k = 2W - 2UW_U - 2JW_J$$

$$\mathcal{L}_{\gamma_*} = 2kW_{\gamma_*}$$
\[ \mathcal{L}_\beta = 2kW_\beta. \]

We are now in a position to write the modulation equations in terms of the derivatives of \( W \). For Equations (58) and (59), we have:

\[ \partial_T W_U + U \partial_X W_U + J \partial_X W_J + W_U U_X + W_J J_X - \partial_X W = 0 \quad (86) \]

\[ \partial_T (2kW_\gamma^\ast) - \partial_X (2kW_\beta) = 0. \quad (87) \]

We now seek to use the variational Equations (56) and (57) to eliminate two parameters from the Whitham system. Using Equation (56) with Equation (68), we have

\[ \mathcal{L}_H = 0 \quad (88) \]

\[ \Rightarrow W_H = \frac{1}{2k}. \quad (89) \]

Similarly for Equation (57):

\[ \mathcal{L}_B = 0 \quad (90) \]

\[ \Rightarrow W_J = 0. \quad (91) \]

Since \( W \) and its derivatives have no explicit dependence on \( k \), then Equation (89) is in fact the dispersion relation for \( k \) in terms of the other parameters \( H, U, J, \gamma^\ast, \beta, \zeta \). Substituting Equation (89) into the modulation equations allows us to eliminate \( k \) entirely. This is particularly relevant for Equation (60):

\[ \partial_T k + \partial_X (kU) = 0 \]

\[ \Rightarrow \partial_T \left( \frac{1}{2W_H} \right) + \partial_X \left( \frac{U}{2W_H} \right) = 0, \]

which simplifies to

\[ \partial_T W_H + U \partial_X W_H - W_H U_X = 0. \]

Equation (86) is already free of \( k \), but Equation (87) can be simplified using Equations (89), (84), and (82):

\[ W_H \partial_T M_\ast - M_\ast \partial_T W_H + U W_H \partial_X M_\ast - U M_\ast \partial_X W_H + W_H M_\ast U_X - W_H^2 J_X = 0. \]

We also observe that Equation (91) can eliminate terms in Equation (86). The four modulation equations are now:

\[ \beta_T + \gamma^\ast X = 0 \quad (92) \]
\[ \partial_t W_H + U \partial_X W_H - W_H U_X = 0 \quad (93) \]
\[ \partial_t W_U + U \partial_X W_U + W_U U_X - \partial_X W = 0 \quad (94) \]
\[ W_H \partial_T M_* - M_* \partial_T W_H + U W_H \partial_X M_* - U M_* \partial_X W_H + W_H M_* U_X - W_H^2 J_X = 0. \quad (95) \]

Recalling the genericity condition \( \sigma \neq 0 \) from Theorem 1, we have that \( \sigma_* = \{W_H, W_J\}_{I, H} \) defined in Appendix C is nonzero, which implies that the derivatives of \( W_J \) with respect to the parameters \( H \) and \( J \) do no vanish simultaneously. We first assume that \( W_{HJ} \neq 0 \). By the implicit function theorem, there exists a continuously differentiable function \( g \) defined on the appropriate parameter space such that

\[ H = g(U, J, \gamma_*, \beta). \quad (96) \]

Next we take derivatives of the equation \( W_J = 0 \):

\[ \partial_J W_J(g, U, J, \gamma_*, \beta) = 0 \]
\[ \Rightarrow g_J W_{HJ} + W_{JJ} = 0 \]

Similarly for the other derivatives:

\[ g_J W_{HJ} = -W_{JJ} \quad (97) \]
\[ g_U W_{HJ} = -W_{UJ} \quad (98) \]
\[ g_{\gamma_*} W_{HJ} = -W_{\gamma_* J} \quad (99) \]
\[ g_\beta W_{HJ} = -W_{\beta J}. \quad (100) \]

Equations (97)–(100) allow us to expand the \( X \) and \( T \) derivatives of \( W_H \) and \( M_* \) in Equations (93)–(95) by using the chain rule. For example,

\[ \partial_T W_H = g_T W_{HH} + J_T W_{HJ} + U_T W_{HU} + \gamma_{*T} W_{H\gamma_*} + \beta_T W_{H\beta} \]
\[ = (g_J T + g_U U_T + g_{\gamma_*} \gamma_{*T} + g_{\beta} \beta_T) W_{HH} + J_T W_{HJ} + U_T W_{HU} + \gamma_{*T} W_{H\gamma_*} + \beta_T W_{H\beta} \]
\[ = (g_J W_{HH} + W_{HJ}) J_T + (g_U W_{HH} + W_{HU}) U_T + (g_{\gamma_*} W_{HH} + W_{H\gamma_*}) \gamma_{*T} \]
\[ + (g_{\beta} W_{HH} + W_{H\beta}) \beta_T. \]
If we multiply the derivative by $W_{HJ}$, we have

$$W_{HJ} \partial_t W_H = (W_{HJ}^2 - W_{HH}W_{JJ})J_T + (W_{H_U}W_{HJ} - W_{HH}W_{UJ})U_T$$
$$+ (W_{H_*}W_{HJ} - W_{HH}W_{*J})\gamma_*T + (W_{H*}W_{HJ} - W_{HH}W_{*J})\beta_*T$$
$$= \{W_{H}, W_{J}\}J_T + \{W_{H}, W_{UJ}\}U_T + \{W_{H}, W_{*J}\}\gamma_*T + \{W_{H}, W_{*J}\}\beta_*T.$$ 

Using Appendix C, we can identify

$$\{W_{H}, W_{J}\}_{J,H} = \sigma_*$$
$$\{W_{H}, W_{*J}\}_{J,H} = -\{W_{H}, W_{*J}\}_{H,J*} = -\rho_*,$$

where we have used the properties of Poisson brackets quoted in Appendix C.

**Remark 3.** An important consideration when computing these Poisson brackets is the order of differentiation and substitution. The correct order is to compute the Poisson bracket and then substitute $H = g(U, J, \gamma_*^*, \beta)$ into the expression, rather than applying the chain rule within a Poisson bracket. This is because the Poisson brackets produce identities that hold regardless of the equations tying the parameters together; we are using them as a convenient notation for leveraging the symmetry of the mixed partial derivatives of $W$. As an example, we make the substitution $H = g(U, J, \gamma_*^*, \beta)$ into the identity $\{W_{H}, W_{*J}\}_{J,H} = -\{W_{H}, W_{*J}\}_{H,J*} = -\rho_*$ instead of computing $\partial_j W_{H}(g, U, J, \gamma_*^*, \beta)$ and other such derivatives.

For $\{W_{H}, W_{UJ}\}_{J,H}$, we have

$$\{W_{H}, W_{UJ}\}_{J,H} = \left\{ W_{H}, \frac{JW_{H}}{2} - \left( \beta + \frac{U}{2} \right) W_{*J} \right\}_{J,H}$$
$$= \{W_{H}, \frac{JW_{H}}{2}\}_{J,H} - \left( \beta + \frac{U}{2} \right) \{W_{H}, W_{*J}\}_{J,H}$$
$$= \nu_* + \left( \beta + \frac{U}{2} \right) \rho_*,$$

and similarly we calculate

$$\{W_{H}, W_{*J}\}_{J,H} = 2\nu_* + U\rho_*,$$

allowing us to write $W_{HJ} \partial_t W_H$ in the following way:

$$W_{HJ} \partial_t W_H = \left( \sigma_* - \rho_* \nu_* + \left( \beta + \frac{U}{2} \right) \rho_* \right) 2\nu_* + U\rho_* \begin{pmatrix} J_T \\ \gamma_*T \\ U_T \\ \beta_*T \end{pmatrix}.$$ 

(101)

Repeating the process of expressing the derivatives in the modulation equations as products of vectors as in Equation (101), we can write the modulation equations as a quasi-linear first-order
system:

$$A \begin{pmatrix} J_T \\ \gamma_{*T} \\ U_T \\ \beta_T \end{pmatrix} + a \begin{pmatrix} J_X \\ \gamma_{*X} \\ U_X \\ \beta_X \end{pmatrix} = 0$$

(102)

with

$$A = \begin{pmatrix} 0 & 0 & 0 & 1 \\ A_{21} & A_{22} & A_{23} & A_{24} \\ A_{31} & A_{32} & A_{33} & A_{34} \\ A_{41} & A_{42} & A_{43} & A_{44} \end{pmatrix}$$

(103)

$$a = \begin{pmatrix} 0 & 1 & 0 & 0 \\ UA_{21} & UA_{22} & UA_{23} - 2\tau & UA_{24} \\ UA_{31} + a_{31} & UA_{32} + a_{32} & UA_{33} + a_{33} & UA_{34} + a_{34} \\ UA_{41} - 2\tau W_H & UA_{42} & UA_{43} + 2\tau M & UA_{44} \end{pmatrix}$$

(104)

and the coefficients (calculated in Appendix D)

$$A_{21} = \sigma_*$$

$$A_{22} = -\rho_*$$

$$A_{23} = \nu_* + \rho_* \left( \beta + \frac{U}{2} \right)$$

$$A_{24} = 2\nu_* + U\rho_*$$

$$A_{31} = \tau_* + \frac{J\sigma_*}{2} + \left( \beta + \frac{U}{2} \right) \Gamma$$

$$A_{32} = -\frac{J}{2} \rho_* - \left( \beta + \frac{U}{2} \right) [W_H, W_{\gamma_*}]_{J,\gamma_*}$$

$$A_{33} = \frac{J}{2} \nu_* + \frac{W_H \mathcal{M}_H}{2} \left( \beta + \frac{U}{2} \right) - \frac{M_* W_H \mathcal{J}_H}{2} + \frac{J}{2} \rho_* \left( \beta + \frac{U}{2} \right) + \left( \beta + \frac{U}{2} \right)^2 [W_H, W_{\gamma_*}]_{J,\gamma_*}$$

$$A_{34} = J\nu_* + W_H \mathcal{M}_H \left( \beta + \frac{U}{2} \right) - M_* W_H \mathcal{J}_H + \frac{J}{2} U\rho_* + U \left( \beta + \frac{U}{2} \right) [W_H, W_{\gamma_*}]_{J,\gamma_*}$$

$$A_{41} = -\Gamma W_H - \sigma_* M_*$$

$$A_{42} = W_H [W_H, W_{\gamma_*}]_{J,\gamma_*} + \rho_* M_*$$

$$A_{43} = -\frac{W_H^2 \mathcal{M}_H}{2} - W_H \left( \beta + \frac{U}{2} \right) [W_H, W_{\gamma_*}]_{J,\gamma_*} - M_* \left( \nu_* + \rho_* \left( \beta + \frac{U}{2} \right) \right)$$

$$A_{44} = -W_H^2 \mathcal{M}_H - UW_H \mathcal{J}_H - M_* (2\nu_* + U\rho_*)$$
\[ a_{31} = W_H W_{JJ} \]
\[ a_{32} = W_H M_{sJ} - W_{HJ} M_s \]
\[ a_{33} = \frac{W^2_H}{2} + J \tau_s - W_H M_{sJ} \left( \beta + \frac{U}{2} \right) \]
\[ a_{34} = W^2_H + UM_s W_{HJ} - UW_H M_{sJ}. \]

If any of the characteristics of the system in Equation (102) are complex, then according to Whitham’s theory, the system is modulationally unstable. Our task is to find the characteristics of Equation (102) by solving for \( X', T' \) in

\[
\det(AX' - aT') = 0, \quad (105)
\]

where \( X' = \frac{dX}{ds} \), \( T' = \frac{dT}{ds} \) along a characteristic curve in the \((X, T)\)-plane parametrized by \( s \). The degenerate case \( X' = T' = 0 \) in Equation (105) corresponds to the nonexistence of \( c_1, c_2 \) not both zero such that

\[
\det(c_1 A + c_2 a) \neq 0. \quad (106)
\]

To demonstrate that our system indeed satisfies Equation (106), consider

\[
\det A = -W_{HJ} \tau_s \left( M_s(\Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{sY_s}) - \frac{W^2_H}{2} (W_H, W_{Y_s})_{H,Y_s} \right)
\]

\[
= -\frac{W_{HJ} \tau_s D}{2^9 \pi^4} D
\]

\[
\neq 0,
\]

where \( D \) is the nonvanishing determinant defined in Theorem 1, which has been calculated in Appendix C as Equation (C2). Hence \( c_2 = 0 \) and any \( c_1 \neq 0 \) satisfies Equation (106), so we do not need to consider the degenerate case. We now focus on computing:

\[
\det(AX' - aT')
\]

\[
\begin{vmatrix}
0 & -T' & 0 & X' \\
A_{21}(X' - UT') & A_{22}(X' - UT') & A_{23}(X' - UT') + 2\tau_s T' & A_{24}(X' - UT') \\
A_{31}(X' - UT') - a_{31} T' & A_{32}(X' - UT') - a_{32} T' & A_{33}(X' - UT') - a_{33} T' & A_{34}(X' - UT') - a_{34} T' \\
A_{41}(X' - UT') + 2\tau_s W_{HJ} T' & A_{42}(X' - UT') & A_{43}(X' - UT') - 2\tau_s MT' & A_{44}(X' - UT')
\end{vmatrix}
\]

\[
(107)
\]

Equation (107) can be written in block form:

\[
\det(AX' - aT') = \begin{vmatrix}
P_{11} & P_{12} \\
P_{21} & P_{22}
\end{vmatrix},
\]

\[
(108)
\]
with

\[ P_{11} = \begin{pmatrix} 0 & -T' \\ A_{21}(X' - UT') & A_{22}(X' - UT') \end{pmatrix} \]

\[ P_{12} = \begin{pmatrix} 0 & X' \\ A_{23}(X' - UT') + 2\tau_s T' A_{24}(X' - UT') \end{pmatrix} \]

\[ P_{21} = \begin{pmatrix} A_{31}(X' - UT') - a_{31} T' & A_{32}(X' - UT') - a_{32} T' \\ A_{41}(X' - UT') + 2\tau_s W_H T' & A_{42}(X' - UT') \end{pmatrix} \]

\[ P_{22} = \begin{pmatrix} A_{33}(X' - UT') - a_{33} T' & A_{34}(X' - UT') - a_{34} T' \\ A_{43}(X' - UT') - 2\tau_s M T' & A_{44}(X' - UT') \end{pmatrix} \].

**Lemma 1.** Under the assumptions of Theorem 1, the matrix

\[ P_{11} = \begin{pmatrix} 0 & -T' \\ A_{21}(X' - UT') & A_{22}(X' - UT') \end{pmatrix} \]

is invertible.

**Proof.** We note that

\[ \det P_{11} = A_{21} T'(X' - UT') = \sigma_* T'(X' - UT'). \] (109)

From Theorem 1, \( \sigma_* \neq 0 \), so \( P_{11} \) is invertible if and only if \( T' \neq 0 \) and \( X' \neq UT' \). If \( T' = 0 \), then

\[ \det(AX' - aT') = X'^4 \det A \]

\[ = -\frac{W_{HH} \tau_*}{2\pi^4} X'^4 D. \]

By assumption, \( W_{HH} \neq 0 \), \( W_H \neq 0 \) (this corresponds to the underlying periodic wave having nonzero period) and hence \( \tau_* = \frac{1}{2} W_H W_{HH} \neq 0 \). Moreover, \( D \neq 0 \) from Theorem 1, hence for \( X', T' \) to solve Equation (105) with \( T' = 0 \), we have

\[ \det(AX' - aT') = 0 \Rightarrow T' = X' = 0, \]

which we exclude as a trivial solution. In fact, if \( T'(s_*) = 0 \) for some value of \( s = s_* \), we have that \( X'(s_*) = 0 \) as well, meaning that the characteristic curve \( (X(s), T(s)) \) terminates at \( s = s_* \). This is not possible, since the characteristic curves are defined for all \( X, T \in \mathbb{R} \), so in fact \( T' \) can never vanish. Next, if \( X' = UT' \), then

\[ \det(AX' - aT') = \begin{vmatrix} 0 & -T' & 0 & UT' \\ 0 & 0 & 2\tau_s T' & 0 \\ -a_{31} T' & -a_{32} T' & -a_{33} T' & -a_{34} T' \\ 2\tau_s W_H T' & 0 & -2\tau_s M T' & 0 \end{vmatrix} \]
\[
\begin{vmatrix}
-2\tau s T' & -a_{31}T' & -a_{32}T' & -a_{34}T' \\
2\tau s W_HT' & 0 & 0 & 0
\end{vmatrix}
= -4\tau^2 s W_HT'^2(a_{34}T'^2 + a_{32}UT'^2)
= -4\tau^2 s W_HT'^4(W^2_H + UM_s W_HJ - UW_HM_s J + U(W_HM_s J - W_HJ M_s))
= -4\tau^2 s W^3_HT'^4.
\]

Only \(T'\) is able to vanish, hence if \(X' = UT'\), then
\[
\text{det}(AX' - aT') = 0 \Rightarrow T' = X' = 0.
\]

There is no nontrivial solution \((X', T')\) of Equation (105) for which \(P_{11}\) is singular, which proves the lemma.

Lemma 1 allows us to use the Schur determinant formula (see, for example,\(^{43}\)) in Equation (108), in particular:
\[
\text{det}(AX' - aT') = \text{det}(P_{11}) \text{det}(P_{22} - P_{21}P^{-1}_{11}P_{12}).
\] (110)

Direct calculation of \(P_{22} - P_{21}P^{-1}_{11}P_{12}\) yields
\[
P_{22} - P_{21}P^{-1}_{11}P_{12} = \begin{pmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{pmatrix},
\]
where
\[
m_{11} = A_{33}(X' - UT') - a_{33}T' - \frac{1}{\sigma_s(X' - UT')} (A_{23}(X' - UT') + 2\tau s T')(A_{31}(X' - UT') - a_{31}T')
\]
(111)

\[
m_{12} = A_{34}(X' - UT') - a_{34}T' + \frac{X'}{T'} (A_{32}(X' - UT') - a_{32}T') - \frac{A_{24}}{\sigma_s} (A_{31}(X' - UT') - a_{31}T')
- \frac{A_{22}X'}{\sigma_s T'} (A_{31}(X' - UT') - a_{31}T')
\]
(112)

\[
m_{21} = A_{43}(X' - UT') - 2\tau s MT' - \frac{1}{\sigma_s(X' - UT')} (A_{23}(X' - UT') + 2\tau s T')(A_{41}(X' - UT') + 2\tau s W_HT')
\]
(113)

\[
m_{22} = \frac{1}{T'} (X' - UT')(A_{42}X' + A_{44}T') - \frac{A_{34}}{\sigma_s} (A_{41}(X' - UT') + 2\tau s W_H T')
\]
(114)
\[- \frac{A_{22}}{\sigma_s T'} (A_{41} (X' - UT') + 2 \tau_s W_H T'). \] 

(115)

We make the substitution \( \lambda = X' - UT' \) and \( \mu = iT' \) (justified by the end result) and note from Equation (110) that

\[
\det(AX' - aT') = \sigma_s (-i \lambda \mu) \left| \begin{array}{ll}
m_{11} & m_{12} \\
m_{21} & m_{22} \\
\end{array} \right|
\]

\[
= \frac{1}{\sigma_s W_H} \left| \begin{array}{ll}
\sigma_s \lambda W_H m_{11} - i \sigma_s \mu W_H m_{12} \\
\sigma_s \lambda m_{21} - i \sigma_s \mu m_{22} \\
\end{array} \right|
\]

which can be simplified to

\[
\det(AX' - aT') = \frac{1}{\sigma_s W_H} \left| \begin{array}{ll}
\alpha_{11}' \lambda^2 + b_{11}' \lambda \mu + c_{11}' \mu^2 & \alpha_{12}' \lambda^2 + b_{12}' \lambda \mu + c_{12}' \mu^2 \\
\alpha_{21}' \lambda^2 + b_{21}' \lambda \mu + c_{21}' \mu^2 & \alpha_{22}' \lambda^2 + b_{22}' \lambda \mu + c_{22}' \mu^2 \\
\end{array} \right|.
\] 

(116)

We calculate the coefficients in Appendix E. To list them, we have

\[
a_{11}' = 2 \tau_s \left( \beta + \frac{U}{2} \right)^2 (\Gamma M_s H + \rho_s M_s j + \sigma_s M_s \gamma_s) - 2 \tau_s \rho_s W_H \left( \beta + \frac{U}{2} \right) - \sigma_s \tau_s M_s - v_s \tau_s W_H
\]

\[
b_{11}' = 2 i \tau_s W_H \left( 2 \beta + 2 \Gamma \left( \beta + \frac{U}{2} \right) + J \sigma_s \right)
\]

\[
c_{11}' = -2 \tau_s W_H^2 W_{ij}
\]

\[
a_{12}' = \rho_s \tau_s W_H - 2 \tau_s \left( \beta + \frac{U}{2} \right) (\Gamma M_s H + \rho_s M_s j + \sigma_s M_s \gamma_s)
\]

\[
b_{12}' = 2 i \tau_s W_H \left( \nu_s - \Gamma + \rho_s \left( \beta + \frac{U}{2} \right) \right)
\]

\[
c_{12}' = 4 \tau_s W_H
\]

\[
a_{21}' = \rho_s \tau_s W_H - 2 \tau_s \left( \beta + \frac{U}{2} \right) (\Gamma M_s H + \rho_s M_s j + \sigma_s M_s \gamma_s) = a_{12}'
\]

\[
b_{21}' = 2 i \tau_s W_H \left( \nu_s - \Gamma + \rho_s \left( \beta + \frac{U}{2} \right) \right) = b_{12}'
\]

\[
c_{21}' = 4 \tau_s W_H = c_{12}'
\]

\[
a_{22}' = 2 \tau_s (\Gamma M_s H + \rho_s M_s j + \sigma_s M_s \gamma_s)
\]

\[
b_{22}' = -4 i \tau_s \rho_s W_H
\]

\[
c_{22}' = 4 \tau_s \nu_s W_H.
\]
We note that the matrix in Equation (116) is symmetric, which simplifies our calculations. Now we perform row and column operations to Equation (116), which will leave the determinant unchanged. Adding \((\beta + \frac{U}{2})\) times the second row to the first row, and then \((\beta + \frac{U}{2})\) times the second column to the first column, we have the following result:

\[
\det(AX' - aT') = \frac{1}{\sigma_* W_H} \begin{vmatrix} Q_{11}(\lambda, \mu) & Q_{12}(\lambda, \mu) \\ Q_{21}(\lambda, \mu) & Q_{22}(\lambda, \mu) \end{vmatrix}.
\]

The polynomials are calculated in Appendix E. We list them as

\[
Q_{11}(\lambda, \mu) = \frac{\tau_*}{2^{15} \pi^5 \sigma_*} (d_2 \lambda^2 + d_1 \lambda \mu + d_0 \mu^2)
\]

\[
Q_{12}(\lambda, \mu) = \frac{\tau_*}{2^{15} \pi^5 \sigma_*} (b_2 \lambda^2 + b_1 \lambda \mu + b_0 \mu^2)
\]

\[
Q_{21}(\lambda, \mu) = Q_{12}(\lambda, \mu)
\]

\[
Q_{22}(\lambda, \mu) = \frac{\tau_*}{2^{15} \pi^5 \sigma_*} (a_2 \lambda^2 + a_1 \lambda \mu + a_0 \mu^2)
\]

We can swap the two columns and then the two rows without changing the determinant:

\[
\det(AX' - aT') = \frac{1}{\sigma_* W_H} \begin{vmatrix} Q_{22}(\lambda, \mu) & Q_{21}(\lambda, \mu) \\ Q_{12}(\lambda, \mu) & Q_{11}(\lambda, \mu) \end{vmatrix}
\]

\[
= \frac{\tau_*^2}{2^{30} \pi^{10} \sigma_*^3 W_H} \begin{vmatrix} a_2 \lambda^2 + a_1 \lambda \mu + a_0 \mu^2 & b_2 \lambda^2 + b_1 \lambda \mu + b_0 \mu^2 \\ b_2 \lambda^2 + b_1 \lambda \mu + b_0 \mu^2 & d_2 \lambda^2 + d_1 \lambda \mu + d_0 \mu^2 \end{vmatrix}
\]

\[
= \frac{W_H W_{JJ}^2}{2^{32} \pi^{10} \sigma_*^3} \det \left( \lambda^2 \begin{pmatrix} a_2 b_2 \\ b_2 d_2 \end{pmatrix} + \lambda \mu \begin{pmatrix} a_1 b_1 \\ b_1 d_1 \end{pmatrix} + \mu^2 \begin{pmatrix} a_0 b_0 \\ b_0 d_0 \end{pmatrix} \right).
\]

This concludes the calculation of \(\det(AX' - aT')\) when \(W_{JJ} \neq 0\). For completeness, we must carry out the same calculation starting with the assumption that \(W_{JJ} \neq 0\) and \(W_{HH} \neq 0\), which is the other case arising from the genericity condition \(\sigma_* \neq 0\). This second calculation is unremarkable, so we give the final result here, but provide some working in Appendix F. In this case, we have, almost exactly as before:

\[
\det(AX' - aT') = -\frac{W_H W_{JJ}^2}{2^{32} \pi^{10} \sigma_*^3} \det \left( \lambda^2 \begin{pmatrix} a_2 b_2 \\ b_2 d_2 \end{pmatrix} + \lambda \mu \begin{pmatrix} a_1 b_1 \\ b_1 d_1 \end{pmatrix} + \mu^2 \begin{pmatrix} a_0 b_0 \\ b_0 d_0 \end{pmatrix} \right),
\]

with the difference being the nonzero factor \(W_{JJ}^2\). This leads us to the following theorem.

**Theorem 3.** Suppose that the assumptions of Theorem 1 hold, that is, \(\sigma \neq 0\) and \(D \neq 0\). Further, assume that \(T_* = 4\pi W_H \neq 0\). Then, the equation for the characteristics of the Whitham modulation equations associated with the nonlinear Schrödinger Equation (1) is equivalent to the normal form for the continuous bands of spectrum emerging from the origin in the spectral plane, given in Theorem 2.
Proof. To solve for the characteristics of the Whitham system, we substitute into Equation (105) the appropriate expression for \( \det(AX' - aT') \) given in either Equation (120) or Equation (121). In both cases, we can divide \( \det(AX' - aT') \) by the constants we have assumed to be nonzero, so \( X' \) and \( T' \) solve the quartic

\[
\det \left( \lambda^2 \begin{pmatrix} a_2 & b_2 \\ b_2 & d_2 \end{pmatrix} + \lambda \mu \begin{pmatrix} a_1 & b_1 \\ b_1 & d_1 \end{pmatrix} + \mu^2 \begin{pmatrix} a_0 & b_0 \\ b_0 & d_0 \end{pmatrix} \right) = 0,
\]

with

\[
\lambda = X' - UT', \quad \mu = i T'.
\]

This is exactly the normal form given in Theorem 2. \( \blacksquare \)

Remark 4. The substitution \( \mu = i T' \) implies that \( T' \in i \mathbb{R} \), however, this is not required for \( (X', T') \) to be a solution to Equation (105). Rather, we can safely make the restriction that \( T' \in i \mathbb{R} \) by multiplying Equation (105) by a phase function \( e^{4if(s)} \) so that \( T' \) becomes purely imaginary and \( X' \mapsto X' e^{if(s)} \) is possibly complex.

Corollary 2. Whitham modulation theory predicts the same criterion for modulational instability as the linear theory given in Corollary 1, that is, the existence of a complex characteristic of the system of modulation equations (Equation (102)) corresponds to a root \( \lambda \) of the normal form Equation (25) with \( \text{Re}(\lambda) \neq 0 \), indicating modulational instability of the underlying wave.

Proof. Noting that \( \det A \neq 0 \) and \( T'(s) \neq 0 \), we may rewrite Equation (105) as

\[
\det \left( X' T' - A^{-1} a \right) = 0.
\]

Since \( T'(s) \neq 0 \) for any \( s \), the characteristic curves may instead be parametrized by \( T \), so that \( \frac{dX}{dT} = \frac{X'(s)}{T'(s)} \). Hence the eigenvalues \( \frac{X'(s)}{T'(s)} \) of \( A^{-1} a \) define the characteristic curves, which is clear once Equation (102) is instead written as

\[
\begin{pmatrix} J_T \\ Y_{*T} \\ U_T \\ \beta_T \end{pmatrix} + A^{-1} a \begin{pmatrix} J_X \\ Y_{*X} \\ U_X \\ \beta_X \end{pmatrix} = 0,
\]

and similarly for Equation (F1). According to the Whitham theory, modulational instability occurs when one of the characteristics of a Whitham system is complex. From Equation (123), this is equivalent to \( \frac{X'}{T'} \in \mathbb{C} \). We have

\[
\frac{X'}{T'} = \frac{\lambda - iU \mu}{-i \mu}.
\]
\[
\frac{i\lambda}{\mu} + U.
\]

We note that \(\mu \in \mathbb{R}\) since it is the Floquet exponent of the periodic solutions to Equation (24), and from Remark 4 we know that this does not restrict the class of characteristic curves. Hence we have that

\[
\frac{X'}{T'} \in \mathbb{C} \iff \text{Re}(\lambda) \neq 0,
\]

which agrees with Corollary 1.

Remark 5. The transformation from the characteristic variables of the Whitham system \((X', T')\) to the spectral variable \(\lambda\) and Floquet exponent \(\mu\) may have greater significance in the scope of rigorously proving the agreement of Whitham modulation theory with linear stability at the origin. In fact, the transformation in all previous examples\(^{27-31}\) is

\[
\lambda = X' - cT', \quad \mu = -\frac{iT'}{T_s},
\]

where \(T_s\) is the period of the underlying wave. To explain the factor of \(\frac{1}{T_s}\), the cited papers all consider the Floquet multiplier to have the form \(e^{i\mu}\), whereas we have chosen to consider \(e^{i\mu T_s}\) in keeping with Ref. 1.

4 | DISCUSSION AND OPEN PROBLEMS

In this paper, we show that the formal Whitham modulation theory correctly predicts the modulational instability of periodic, travelling wave solutions of the general nonlinear Schrödinger Equation (1) as prescribed by the rigorous spectral analysis at the origin in Ref. 1. Applying the variational principle to the averaged Lagrangian allows us to derive four modulation equations, which we then homogenize using the genericity conditions described in Ref. 1. This results in two cases depending on which slowly varying parameters we eliminate, however, the calculations are essentially the same. Finally, we compute a quartic equation for the characteristics of the homogenized modulation equations from the determinant of the quasi-linear system Equation (102). By invoking various determinant identities inspired by the proof of [Ref. 1, Proposition 1] and also a change of variables, we deduce that the characteristics of the Whitham system satisfy the same quartic equation as the normal form for the four continuous bands of spectrum at the origin.

Leisman et al. also provide a modulational instability criterion for transverse perturbations, where they consider the stability of periodic solutions of Equation (1) to the two-dimensional equation:

\[
i\psi_t = \psi_{xx} \pm \psi_{zz} + \xi f(|\psi|^2)\psi.
\]

The extension is neat from the perspective of the linear theory, however, we believe extending the Whitham theory would involve a two-phase approach, making the homogenization process considerably more difficult. We have decided that this lies outside the scope of this paper.
One interesting future direction for our results would be to compute Riemann invariants and investigate the behavior of dispersive shock waves for suitable one-dimensional potentials \( f(|\psi|^2) \). This would involve diagonalizing the matrix \( A^{-1}a \) from the quasi-linear system Equation (102).

Another obvious extension would be to consider a coupled general nonlinear Schrödinger system:

\[
\begin{align*}
    i\psi_{1t} &= \psi_{1xx} + \zeta_1 f(\zeta_1 |\psi_1|^2, \zeta_2 |\psi_2|^2)\psi_1 \\
    i\psi_{2t} &= \psi_{2xx} + \zeta_2 f(\zeta_1 |\psi_1|^2, \zeta_2 |\psi_2|^2)\psi_2,
\end{align*}
\]

which has the Lagrangian:

\[
L = i(\overline{\psi}_1 \psi_{1t} - \psi_1 \overline{\psi}_{1t}) + i(\overline{\psi}_2 \psi_{2t} - \psi_2 \overline{\psi}_{2t}) + 2|\psi_{1x}|^2 + 2|\psi_{2x}|^2 - 2F(\zeta_1 |\psi_1|^2, \zeta_2 |\psi_2|^2).
\]

More generally, we could couple \( n \) general nonlinear Schrödinger equations together, which yields

\[
\begin{align*}
    i\partial_t \psi &= \partial_x^2 \psi + \nabla \psi F(|\psi_1|^2, \ldots, |\psi_n|^2) \\
    L &= i(\overline{\psi} \cdot \partial_t \psi - \psi \cdot \partial_t \overline{\psi}) + 2|\partial_x \psi|^2 - 2F(|\psi_1|^2, \ldots, |\psi_n|^2),
\end{align*}
\]

where \( F \) is a scalar potential. We believe that the Whitham theory for these systems would closely resemble the procedure for Equation (1), however, difficulty may arise in the homogenization process. In particular, one must find suitable genericity conditions to eliminate enough slowly varying parameters.

In the context of the recent work of Chen et al., \(^{44}\) Theorem 3 implies that a set of complex characteristics of the Whitham modulation equations supports rogue wave solutions localized on the background of periodic standing wave solutions of the focusing NLS equation. On the other hand, it appears that the existence of real characteristics is a necessary (but not sufficient) condition for observing algebraic solitons travelling on the background of periodic standing waves. More research is needed before this connection is rigorously established.

Finally, we cite the open problem of proving that the modulational instability criterion derived from the hyperbolicity of a Whitham modulation system coincides with spectral instability of a periodic travelling wave solution of some general class of PDEs. The difficulty in developing a general proof lies in the homogenization of the Whitham equations. This process is guided by genericity conditions that are determined from the underlying PDE in the course of the rigorous linearized spectral analysis; this explains the disparity among the analyses of Refs. \(^{27–31}\) and this paper. On the other hand, it is promising that the same transformation between the characteristics of the Whitham system and the spectral variables (Equation (122)) appears in the cited examples where the Whitham theory has been rigorously verified.

**APPENDIX A: POISSON BRACKETS FROM THE LINEAR THEORY**

We first define the Poisson brackets:

\[
\gamma = \{T_\ast, \eta\}_{\kappa, \omega} \quad \rho = \{T_\ast, \eta\}_{\omega, E} \quad \tau = \frac{T_\ast T_{*E}}{2}
\]

\[
\nu = -\frac{T_\ast T_{*E}}{2} \quad \xi = \{T_\ast, \eta\}_{\kappa, \xi} \quad \chi = \{T_\ast, \eta\}_{\xi, E}.
\]

With these definitions, we can list the matrix entries in Equation (25):

\[
a_2 = -\frac{\sigma}{2}(\gamma M_E + \rho M_\kappa + \sigma M_\omega)
\]

\[
b_2 = -\frac{\sigma \rho T_\ast}{2} = -\sigma(\tau M_E + \nu M_\kappa)
\]

\[
d_2 = -\frac{\sigma}{2}(\nu T_\ast + \frac{\sigma}{2}M)
\]
\[ a_1 = 2i\sigma \rho T_* \]
\[ b_1 = i\sigma T_* (\nu + \gamma) \]
\[ d_1 = i\sigma T_* (2\tau + \sigma \kappa) \]
\[ a_0 = 2\sigma \nu T_* \]
\[ b_0 = 2\sigma \tau T_* \]
\[ d_0 = 2\sigma T_* (\omega \gamma - \zeta \xi - E \sigma). \]

**APPENDIX B: RELATIONS BETWEEN \( K \) and \( W \)**

In this appendix, we give the relations between the derivatives of \( K \) and the derivatives of \( W \), defined in Equations (14) and (67) respectively. This is carried out by taking a derivative of Equation (78) with respect to one of the parameters \( H, U, J, \gamma, \beta, \zeta \) and then applying the chain rule, simplifying the results using Equations (74)–(76). Finally, we use Equations (15)–(17) to eliminate \( K \). For the period \( T_* = K_E \) in the linear theory:

\[ T_* = 4\pi W_H \]
\[ T_{*E} = 16\pi W_{HH} \]
\[ T_{*K} = 16\pi \left(W_{HJ} - \left(\beta + \frac{U}{2}\right)W_{HH}\right) = -16\pi \eta_{*H} \]
\[ T_{*\omega} = -4\pi M_H. \]

Next, for \( \eta \) we have:

\[ \eta = 4\pi \eta_* \]
\[ \eta_E = 16\pi \eta_{*H} \]
\[ \eta_K = 16\pi \left(\eta_{*J} - \left(\beta + \frac{U}{2}\right)\eta_{*H}\right) \]
\[ \eta_\omega = -4\pi \eta_{*\gamma}. \]

Finally for \( M \):

\[ M = 2\pi M_* \]
\[ M_E = 8\pi M_{*H} \]
\[ M_K = 8\pi \left(M_{*J} - \left(\beta + \frac{U}{2}\right)M_{*H}\right) \]
\[ M_\omega = -2\pi M_{*\gamma}. \]
Since $\zeta$ is the same parameter for both cases, we have that:

$$K_\zeta = \pi W_\zeta.$$

**APPENDIX C: POISSON BRACKETS FOR THE MODULATION EQUATIONS**

Similarly to the Poisson brackets in Appendix A, we make the following definitions for Poisson brackets for the Whitham system:

$$\sigma_* = \{W_H, \eta_\ast\}_{H,J} = \{W_H, W_J\}_{J,H}$$

$$\rho_* = \{W_H, \eta_\ast\}_{\gamma,H} = \{W_H, W_J\}_{H,\gamma}$$

$$\Gamma = \{W_H, \eta_\ast\}_{J,\gamma} = \{W_H, W_J\}_{\gamma,J}$$

$$\nu_* = -\frac{1}{2} W_HW_{HH}$$

$$\tau_* = \frac{1}{2} W_HW_{HJ}$$

$$\xi_* = \{W_H, \eta_\ast\}_{J,J} = \{W_H, W_J\}_{J,J}$$

$$\chi_* = \{W_H, \eta_\ast\}_{J,H} = \{W_H, W_J\}_{H,J}.$$  

The reason we have included the Poisson brackets in terms of $W_J$ as well as $\eta_\ast$ is because it is more straightforward to use the symmetry of mixed partial derivatives of $W$ when using $W_J$.

We make extensive use of several properties of Poisson brackets. Let $P, Q, S$ be functions of $w, x, y, z$ with symmetric mixed partial derivatives. Then:

- $\{P, Q\}_{w,x} = -\{P, Q\}_{x,w} = -\{Q, P\}_{w,x};$
- $\{P_w, Q_x\}_{y,z} = \{P_y, Q_z\}_{w,x};$
- $\{P, P\}_{w,x} = 0;$
- $\{PQ, S\}_{w,x} = P\{Q, S\}_{w,x} + Q\{P, S\}_{w,x};$
- $\{\alpha P, Q\}_{w,x} = \alpha\{P, Q\}_{w,x}$ for a constant $\alpha$.

The above definitions allow us to express the equivalent Poisson brackets in Appendix A in terms of these newly defined Poisson brackets for the Whitham parameters:

$$\sigma = 256\pi^2 \sigma_*$$

$$\rho = -64\pi^2 \rho_*$$

$$\gamma = -64\pi^2 \left( \Gamma + \left( \beta + \frac{U}{2} \right) \rho_* \right)$$

$$\nu = 64\pi^2 \nu_*$$

$$\tau = 64\pi^2 \left( \tau_* + \left( \beta + \frac{U}{2} \right) \nu_* \right)$$
\[ \chi = 64\pi^2 \chi_* \]
\[ \xi = 64\pi^2 \left( \xi_* + \left( \beta + \frac{U}{2} \right) \chi_* \right). \]

Ultimately, we use these relations to express the matrix entries of Equation (25) (given in Appendix A) in terms of the Whitham parameters:

\[
\begin{align*}
    a_2 &= 2^{16} \pi^5 \sigma_* (\Gamma M_{sH} + \rho_* M_{sJ} + \sigma_* M_{\gamma_*}) \\
    b_2 &= 2^{15} \pi^5 \rho_* \sigma_* W_H = -2^{16} \sigma_* (\tau_* M_{sH} + \nu_* M_{sJ}) \\
    d_2 &= -2^{15} \pi^5 \sigma_* (\nu_* W_H + \sigma_* M_*) \\
    a_1 &= -2^{17} i \pi^5 \sigma_* \rho_* W_H \\
    b_1 &= 2^{16} i \pi^5 \sigma_* W_H \left( \nu_* - \Gamma - \left( \beta + \frac{U}{2} \right) \rho_* \right) \\
    d_1 &= 2^{16} i \pi^5 \sigma_* W_H (2\tau_* + 2 \left( \beta + \frac{U}{2} \right) \nu_* + J \sigma_*) \\
    a_0 &= 2^{17} \pi^5 \sigma_* \nu_* W_H \\
    b_0 &= 2^{17} \pi^5 \sigma_* W_H \left( \tau_* + \left( \beta + \frac{U}{2} \right) \nu_* \right). \\
\end{align*}
\]

For the last entry \( d_0 \), we use the identity:

\[ W = 2W_H \left( H + \beta J + \frac{U J}{2} \right) - 2M_* \left( \beta U + \frac{U^2}{4} - \gamma_* \right) - J \eta_* - 2\xi W_\xi. \] \hspace{1cm} (C1)

In particular, taking Poisson brackets of Equation (C1) with \( W_J \) and derivatives with respect to \( H \) and \( J \), and using the fact that \( W_J = 0 \) in Equation (91) yields

\[ W_H \eta_{sJ} = -\sigma_* \left( 2H + \beta J + \frac{U J}{2} \right) - 2\Gamma \left( \beta U + \frac{U^2}{4} - \gamma_* \right) - 2\xi \xi_* \]

Similarly, we have for a Poisson bracket of Equation (C1) with \( W_H \) and derivatives \( H \) and \( J \):

\[ W_{HH} \eta_{sH} = 2\rho_* \left( \beta U + \frac{U^2}{4} - \gamma_* \right) + J \sigma_* + 2\xi \chi_* \]

Hence

\[ d_0 = 2\sigma T_* (\omega \gamma - \xi \chi - E \sigma) \]
\[ = 2^{17} \pi^5 \sigma_* W_H \left( - \left( \beta U + \frac{U^2}{4} - \gamma_* \right) \Gamma - \xi \xi_* - \left( H + \beta J + \frac{U J}{2} \right) \sigma_* \right) \]
\[
- \left( \beta + \frac{U}{2} \right) \left( \rho_s \left( \beta + \frac{U^2}{4} - \gamma_s \right) + \zeta \chi_s \right) \\
= 2^{16} \pi^5 \sigma_s W_{H}^2 \left( \eta_{sJ} - \eta_{sH} \left( \beta + \frac{U}{2} \right) \right).
\]

Now writing \( \eta_{sH}, \eta_{sJ} \) as the derivatives of \( W_J \) using its definition in Equation (80), we see that

\[
d_0 = 2^{16} \pi^5 \sigma_s W_{H}^2 \left( 2W_{HJ} \left( \beta + \frac{U}{2} \right) - W_{JJ} - \left( \beta + \frac{U}{2} \right)^2 W_{HH} \right) \\
= 2^{16} \pi^5 \sigma_s W_{H} \left( 4 \tau_s \left( \beta + \frac{U}{2} \right) + 2 \nu_s \left( \beta + \frac{U}{2} \right)^2 - W_{H} W_{JJ} \right).
\]

We also provide a calculation of the determinant \( D \) from Theorem 1 in terms of the Whitham parameters:

\[
D = -\frac{4}{\sigma_s^3} (a_2 d_2 - b_2^2) \\
= -\frac{4}{2^{24} \pi^6} \left( 2^{16} \pi^5 \sigma_s (\Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s})(-2^{15} \pi^5 \sigma_s (\nu_s W_H + \sigma_s M_s) \right) \\
- (2^{16} \pi^5 \sigma_s (\tau_s M_{sH} + \nu_s M_{sJ})^2) \\
= -\frac{2^9 \pi^4}{\sigma_s} \left( - (\Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s})(\nu_s W_H + \sigma_s M_s) - 2(\tau_s M_{sH} + \nu_s M_{sJ})^2 \right) \\
= \frac{2^9 \pi^4}{\sigma_s} \left( \sigma_s M_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) + \nu_s W_H \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) \\
+ \frac{W_{H}^2}{2} (W_{HJ} M_{sH} - W_{HH} M_{sJ})^2 \right) \\
= 2^9 \pi^4 \left( M_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) + \frac{W_{H}^2}{2\sigma_s} \left( - W_{HH} \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) \\
+ W_{HJ} M_{sH} - 2 W_{HJ} W_{HH} M_{sH} M_{sJ} + W_{HH} M_{sJ}^2 \right) \right) \\
= 2^9 \pi^4 \left( M_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) - \frac{W_{H}^2}{2\sigma_s} \left( \sigma_s W_{HHH} M_{\gamma s} + W_{HHH} M_{sH}(M_{sH} W_{JJ} - W_{HJ} M_{sJ}) \\
+ W_{HHM_{sJ}}(W_{HMM_{sJ}} - W_{HH} M_{sH}) - W_{HJ}^2 M_{sJ}^2 + 2 W_{HJ} W_{HMM_{sJ}} M_{sJ} - W_{HJ}^2 M_{sJ}^2 \right) \right) \\
= 2^9 \pi^4 \left( M_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) - \frac{W_{H}^2}{2\sigma_s} \left( \sigma_s W_{HHH} M_{\gamma s} - M_{sH}^2 (W_{HJ}^2 - W_{HHH} W_{JJ}) \right) \right) \\
= 2^9 \pi^4 \left( M_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) - \frac{W_{H}^2}{2\sigma_s} \left( \sigma_s W_{HHH} M_{\gamma s} - \sigma_s M_{sH}^2 \right) \right) \\
= 2^9 \pi^4 \left( M_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma s} \right) - \frac{W_{H}^2}{2\sigma_s} \left( \sigma_s W_{HHH} M_{\gamma s} - \sigma_s M_{sH}^2 \right) \right)
\]
from which we have

\[
D = 2^9 \pi^4 \left( M \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{s\gamma_s} \right) - \frac{W_H^2}{2} \{ W_{H}, W_{\gamma_s} \}_{H,\gamma_s} \right).
\]

(C2)

APPENDIX D: CALCULATING MATRIX ELEMENTS

In this appendix, we provide some calculations for the matrix elements of Equation (103) and (104). We already calculated \( A_{21}, A_{22}, A_{23}, A_{24} \) in Equation (101). For Equation (94), we compute:

\[
W_{HH} \partial_T W_U = \{ W_{UU}, W_J \}_{H,H} J_T + \{ W_{U}, W_J \} \gamma_s, H \gamma_s + \{ W_{UU}, W_J \}_{U,H} U_T + \{ W_{U}, W_J \}_{\beta,H} \beta_T
\]

\[
= \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_J \right\} J_T + \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_J \right\} \gamma_s T
\]

\[
+ \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_J \right\} U_T + \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_J \right\} \beta_T
\]

\[
= \left( \tau_s + \frac{J}{2} \sigma_s + \Gamma \left( \beta + \frac{U}{2} \right) \right) J_T + \left( -\frac{J}{2} \rho_s - \left( \beta + \frac{U}{2} \right) \right) \{ W_{H}, W_{\gamma_s} \}_{H,J} \gamma_s T
\]

\[
+ \left( \frac{J}{2} \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_H \right\} - \frac{1}{2} M_s W_{HJ} - \left( \beta + \frac{U}{2} \right) \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_H \right\} \gamma_s J \right) U_T
\]

\[
+ \left( \frac{J}{2} \left\{ \frac{JW_H}{2} - W_{\gamma_s} \left( \beta + \frac{U}{2} \right), W_H \right\} - \frac{1}{2} M_s W_{HJ} + \frac{1}{2} W_{H} M_{sH} \left( \beta + \frac{U}{2} \right) + \left( \beta + \frac{U}{2} \right)^2 \{ W_{H}, W_{\gamma_s} \}_{H,J} \right) \beta_T
\]

\[
= A_{31} J_T + A_{32} \gamma_s T + A_{33} U_T + A_{34} \beta_T.
\]

For \( A_{31}, A_{32}, A_{33}, A_{34} \):

\[
W_{HH} W_U U_X - W_{HJ} \partial_X W = W_{HH} W_U U_X - \{ W, W_J \}_{H,H} J_X - \{ W, W_J \}_{\gamma_s, H} \gamma_s X
\]

\[
- \{ W, W_J \}_{U,H} U_X - \{ W, W_J \}_{\beta,H} \beta_X
\]

\[
= W_{H} W_{HJ} J_X - (M_s W_{HJ} - W_{H} M_{sJ}) \gamma_s X + W_{H} W_{UJ} U_X
\]

\[
- (W_{HJ} \Gamma W_{H} - W_{H} \Gamma W_{\beta}) \beta_X.
\]

Taking the \( J \)-derivatives of \( W_U \) and \( W_\beta \) defined in Equations (83) and (84) respectively, we have

\[
W_{HH} W_U U_X - W_{HJ} \partial_X W = W_{H} W_{HJ} J_X - (M_s W_{HJ} - W_{H} M_{sJ}) \gamma_s X + W_{H} \left( \frac{1}{2} W_{H} + \frac{J}{2} W_{HJ} - M_{sJ} \left( \beta + \frac{U}{2} \right) \right) U_X
\]

\[
- (W_{HJ} \Gamma W_{H} - W_{H} \Gamma W_{\beta}) \beta_X.
\]
\[
= W_HW_JX - (M_xW_HH - W_HM_{sJ})\gamma_x + \left(\frac{1}{2}W_H^2 + J\tau + W_HM_{sJ} \left(\beta + \frac{U_H}{2}\right)\right)U_X
- (-W_H^2 + UW_HM_{sJ} - UM_xW_H)\beta_X
= a_{31}J_X + a_{32}\gamma_x + a_{33}U_X + a_{34}\beta_X.
\]

Finally, in Equation (95), we compute
\[
W_{HJ}W_H\partial_JM_s = W_{HJ}(W_{HJ},W_{\gamma_x},J_T + W_{HJ}(W_{HJ},W_{\gamma_x},J_{sT}) + W_{HJ}(W_{HJ},W_U)J_{sT} + W_{HJ}(W_{HJ},W_{\beta})J_{sT} = -W_H\Gamma J_T + W_{HJ}(W_{HJ},W_{\gamma_x},J_{sT}) + W_{HJ}(W_{HJ},W_{\gamma_x},J_{sT}) - U_{W_{HJ},W_{\gamma_x},J_{sT}}\beta_T
+ W_{HJ}(W_{HJ},W_{\gamma_x},J_{sT}) + W_{HJ}(W_{HJ},W_{\gamma_x},J_{sT}) - U_{W_{HJ},W_{\gamma_x},J_{sT}}\beta_T.
\]

Hence for \(A_{41}, A_{42}, A_{43}, A_{44}\), we have:
\[
W_{HJ}W_H\partial_JM_s - W_{HJ}M_s\partial_JW_H
= (-\Gamma W_H - \sigma_s M_s)J_T + (W_{HJ}(W_{HJ},W_{\gamma_x},J_T) + \rho_s M_s)
+ \left(-\frac{1}{2}W_{HJ}^2M_{sH} - W_{HJ}(\beta + \frac{U}{2})\right)\{W_{HJ},W_{\gamma_x},J_T - M_s(\nu_s + \rho_s (\beta + \frac{U}{2})\}
+ (-W_{HJ}^2M_{sH} - U_{W_{HJ},W_{\gamma_x},J_T} - M_s(2\nu_s + U\rho_s))
= A_{41}J_T + A_{42}\gamma_x + A_{43}U_T + A_{44}\beta_T.
\]

The \(X\)-derivatives of Equation (95) are:
\[
U(W_{HJ}W_H\partial_XM_s - W_{HJ}M_s\partial_XW_H) + W_{HJ}W_HM_sU_X = W_{HJ}W_H^2J_X
= (UA_{41} - 2\tau_sW_H)J_X + UA_{42}\gamma_x + (UA_{43} + 2\tau M_s)U_X + UA_{44}\beta_X.
\]

**APPENDIX E: MATRIX ELEMENTS FOR THE SCHUR DETERMINANT CALCULATION**

In this appendix, we calculate the coefficients in Equation (116), using the expressions for \(m_{11}, m_{12}, m_{21}, m_{22}\) computed in Equation (111) and (113)–(115). We derive a number of useful identities that we use freely in the subsequent calculations:
\[
\sigma_s(W_{HJ}M_{\gamma_x} - M_{sJ}M_{sJ}) = (M_{sJ}W_{HJ}M_{sJ} - M_{sJ}W_{HJ})(M_{sJ}W_{HJ}M_{sJ} - M_{sJ}W_{HJ})
= W_{HJ}\sigma_sM_{\gamma_x} - M_{sJ}M_{sJ}(W_{HJ}^2 - W_{HJ}M_{sJ}).
\]
\[- \left( M_r M_s W_{HH} W_{JJ} - M_r^2 W_{HH} W_{JJ} - M_r^2 W_{HH} W_{HI} + M_s W_{HH} W_{JJ}^2 \right) \]
\[= W_{HH} \left( \Gamma \sigma_{s} + \rho_{s} \sigma_{s} \right), \]
\[= \frac{1}{2} \left( \sigma_{s} W_{HI} - \nu_{s} \Gamma \right) \]
\[= \frac{1}{2} W_{HI} \left( M_s W_{HH} - M_{sH} W_{HI} \right) \]
\[= -\tau_{s} \sigma_{s}, \]
\[= \frac{1}{2} \sigma_{s} W_{HI} M_{sH} - \nu_{s} \Gamma \]
\[= \frac{1}{2} W_{HI} \left( M_{sH} W_{HI} - M_{sH} W_{HI} \right) \]
\[= -2\tau_{s} \sigma_{s}. \]

For the coefficients $a'_{11}, b'_{11}, c'_{11}$, we have

\[a'_{11} = W_{HI} \left( \sigma_{s} A_{33} - A_{23} A_{31} \right) \]
\[= W_{HI} \left[ \frac{J}{2} \nu_{s} \sigma_{s} + \frac{J}{2} \rho_{s} \sigma_{s} \left( \beta + \frac{U}{2} \right) - \frac{1}{2} \sigma_{s} M_{sH} W_{HI} + \frac{1}{2} \sigma_{s} W_{HI} M_{sH} \left( \beta + \frac{U}{2} \right) \right. \]
\[+ \left. \frac{J}{2} \left( \sigma_{s} W_{HI} W_{JJ} - \nu_{s} \left( \beta + \frac{U}{2} \right) \right) \left( \sigma_{s} W_{HI} W_{JJ} - \nu_{s} \Gamma \right) \right] \]
\[= W_{HI} \left[ \left( \beta + \frac{U}{2} \right)^2 \sigma_{s} W_{HI} W_{JJ} - \nu_{s} \Gamma \right] \]
\[ b'_{11} = iW_H(\sigma_4 a_{33} - A_{23} a_{31} + 2\tau_4 A_{31}) \]
\[ = iW_H \left( \frac{W_H^2}{2} \sigma_4 + J\tau_4 \sigma_4 - W_H M_{4J} \sigma_4 \left( \beta + \frac{U}{2} \right) \right) \]
\[ - W_H W_{JJ} \left( \nu_4 + \rho_4 \left( \beta + \frac{U}{2} \right) \right) + 2\tau_4 \left( \tau_4 + \frac{J\sigma_4}{2} + \Gamma \left( \beta + \frac{U}{2} \right) \right) \]
\[ = iW_H \left( \frac{W_H^2}{2} \sigma_4 - \nu_4 W_H W_{JJ} + 2\tau_4^2 + 2J\tau_4 \sigma_4 + (2\tau_4 \Gamma - W_H W_{JJ} \rho_4 - W_H M_{4J} \sigma_4) \left( \beta + \frac{U}{2} \right) \right) \]
\[ = iW_H \left( 4\tau_4^2 + 2J\tau_4 \sigma_4 + 4\tau_4 \Gamma \left( \beta + \frac{U}{2} \right) \right) \]
\[ c'_{11} = -2\tau_4 W_H a_{31} \]
\[ = -2\tau_4 W_H^2 W_{JJ}. \]

Next for \( a'_{12}, b'_{12}, c'_{12}: \)
\[ a'_{12} = W_H(\sigma_4 A_{32} - A_{22} A_{31}) \]
\[ = W_H \left[ -\frac{J}{2} \rho_4 \sigma_4 - \sigma_4 \left( \beta + \frac{U}{2} \right) \{ W_H, W_{\gamma_4} \}_{J,\gamma_4} + \rho_4 \left( \tau_4 + \frac{J\sigma_4}{2} + \Gamma \left( \beta + \frac{U}{2} \right) \right) \right] \]
\[ = W_H \left[ \left( \beta + \frac{U}{2} \right) \left( \rho_4 \Gamma - \sigma_4 \{ W_H, W_{\gamma_4} \}_{J,\gamma_4} \right) + \tau_4 \rho_4 \right] \]
\[ = \tau_4 \rho_4 W_H - 2\tau_4 \left( \beta + \frac{U}{2} \right) \left( \Gamma M_{4H} + \rho_4 M_{4J} + \sigma_4 M_{4\gamma_4} \right) \]
\[ b'_{12} = -iW_H \left[ \sigma_4 A_{34} + \sigma_4 U A_{32} - \sigma_4 a_{32} - A_{24} A_{31} - U A_{22} A_{31} + A_{22} a_{31} \right] \]
\[ = -iW_H \left[ J\nu_4 \sigma_4 + \sigma_4 W_{HH} M_{4H} \left( \beta + \frac{U}{2} \right) - \sigma_4 M_{4H} W_{JJ} + \frac{J}{2} U \rho_4 \sigma_4 + U \sigma_4 \left( \beta + \frac{U}{2} \right) \{ W_H, W_{\gamma_4} \}_{J,\gamma_4} \right] \]
\[ - \frac{J}{2} U \rho_4 \sigma_4 - U \sigma_4 \left( \beta + \frac{U}{2} \right) \{ W_H, W_{\gamma_4} \}_{J,\gamma_4} - \nu_4 W_{HH} M_{4J} + \sigma_4 W_{HH} M_{4*} \]
\[ - (2\nu_4 + U \rho_4) \left( \tau_4 + \frac{J\sigma_4}{2} + \Gamma \left( \beta + \frac{U}{2} \right) \right) + U \rho_4 \left( \tau_4 + \frac{J\sigma_4}{2} + \Gamma \left( \beta + \frac{U}{2} \right) \right) - \rho_4 W_H W_{JJ} \]
\[ = -iW_H \left[ -2\nu_4 \tau_4 - W_{HH} (\sigma_4 M_{4J} + \rho_4 W_{JJ}) + \left( \beta + \frac{U}{2} \right) (\sigma_4 W_{HH} M_{4H} - 2\nu_4 \Gamma) \right] \]
\[ = 2i\tau_4 W_H \left( \nu_4 - \Gamma + \rho_4 \left( \beta + \frac{U}{2} \right) \right) \]
\[ c'_{12} = W_H \left[ \sigma_4 a_{34} + \sigma_4 U a_{32} - A_{24} a_{31} - U A_{22} a_{31} \right] \]
\[ W_H \left[ \sigma_s(W_H^2 + UM_sW_{HJ} - UW_HM_{sJ}) + U\sigma_s(W_HM_{sJ} - W_HM_s) \right] \\
- W_H W_{J2}(2\nu_s + U\rho_s) + U\rho_sW_H W_{JJ} \]
\[ = W_H \left[ \sigma_sW_H^2 - 2\nu_sW_H W_{JJ} \right] \\
= W_H^3 W_{HJ}^2 \\
= 4\tau^2 W_H. \]

Now for \( a'_{21}, b'_{21}, c'_{21} \):
\[ a'_{21} = \sigma_sA_{43} - A_{23}A_{41} \]
\[ = \sigma_s \left( -\frac{W_H^2M_{sH}}{2} - W_H \left( \beta + \frac{U}{2} \right) \{W_H, W_{\gamma_s}\}_{J,J_s} - M_s \left( \nu_s + \rho_s \left( \beta + \frac{U}{2} \right) \right) \right) \\
- \left( \nu_s + \rho_s \left( \beta + \frac{U}{2} \right) \right) (-\Gamma W_H - \sigma_s M_s) \]
\[ = W_H \left( \beta + \frac{U}{2} \right) (\rho_s \Gamma - \sigma_s \{W_H, W_{\gamma_s}\}_{J,J_s}) + \nu_s \Gamma W_H - \frac{W_H^2}{2} \sigma_s M_{sH} \]
\[ = -2\tau \left( \beta + \frac{U}{2} \right) (\Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma_s}) + \tau \rho_s W_H \]
\[ b'_{21} = i(2\tau_s\sigma_s M_s + 2\tau_s W_H A_{23} + 2\tau_s A_{41}) \]
\[ = 2i\tau_s \left( \sigma_s M_s + W_H \left( \nu_s + \rho_s \left( \beta + \frac{U}{2} \right) \right) \right) - \Gamma W_H - \sigma_s M_s \]
\[ = 2i\tau_s W_H \left( \nu_s - \Gamma + \rho_s \left( \beta + \frac{U}{2} \right) \right) \]
\[ c'_{21} = 4\tau^2 W_H. \]

Finally for \( a'_{22}, b'_{22}, c'_{22} \):
\[ a'_{22} = \sigma_s A_{42} - A_{22}A_{41} \]
\[ = \sigma_s \{W_H, W_{\gamma_s}\}_{J,J_s} + \rho_s M_s \}
\[ = W_H \left( \sigma_s \{W_H, W_{\gamma_s}\}_{J,J_s} - \rho_s \Gamma \right) \]
\[ = 2\tau_s \left( \Gamma M_{sH} + \rho_s M_{sJ} + \sigma_s M_{\gamma_s} \right) \]
\[ b'_{22} = -i(U\sigma_s A_{42} + \sigma_s A_{44} - A_{24}A_{41} - 2\tau_s W_H A_{22} - UA_{22}A_{41}) \]
\[ = -i(U\sigma_s \{W_H, W_{\gamma_s}\}_{J,J_s} + \rho_s M_s) + \sigma_s (-W_H^2 M_{sH} - UW_H \left\{W_H, W_{\gamma_s}\}_{J,J_s} - M_s (2\nu_s + U\rho_s)) \\
- (2\nu_s + U\rho_s) (-\Gamma W_H - \sigma_s M_s) + 2\tau_s \rho_s W_H + U\rho_s (-\Gamma W_H - \sigma_s M_s) \]
\[ = -i (-\sigma_s W_H^2 M_{sH} + 2\nu_s \Gamma W_H + 2\tau_s \rho_s W_H) \]
\[ c'_{22} = 2\tau_\nu W_H A_{24} + 2\tau_\nu U W_H A_{22} \]
\[ = 2\tau_\nu W_H (2\nu_* + U \rho_* - U \rho_*) \]
\[ = 4\tau_\nu \nu_* W_H. \]

For the calculation of the quadratics in Equation (117), we have

\[
Q_{11}(\lambda, \mu) = \left[ a'_{11} + \left( \beta + \frac{U}{2} \right) a'_{21} + \left( \beta + \frac{U}{2} \right) a'_{12} + \left( \beta + \frac{U}{2} \right) a'_{22} \right] \lambda^2 \\
+ \left[ b'_{11} + \left( \beta + \frac{U}{2} \right) b'_{21} + \left( \beta + \frac{U}{2} \right) b'_{12} + \left( \beta + \frac{U}{2} \right) b'_{22} \right] \lambda \mu \\
+ \left[ c'_{11} + \left( \beta + \frac{U}{2} \right) c'_{21} + \left( \beta + \frac{U}{2} \right) c'_{12} + \left( \beta + \frac{U}{2} \right) c'_{22} \right] \mu^2 \\
= -\tau_* [\nu_* W_H + \sigma_* M_*] \lambda^2 + 2i\tau_* W_H \left[ 2\tau_* + 2 \left( \beta + \frac{U}{2} \right) \nu_* + J \sigma_* \right] \lambda \mu \\
+ 2\tau_* W_H \left[ 4\tau_* \left( \beta + \frac{U}{2} \right) + 2\nu_* \left( \beta + \frac{U}{2} \right)^2 - W_H W_{JJ} \right] \mu^2 \\
= \frac{\tau_*}{2^{15} \pi^5 \sigma_*} (d_2 \lambda^2 + d_1 \lambda \mu + d_0 \mu^2). \]

Next:

\[
Q_{12}(\lambda, \mu) = \left[ a'_{12} + \left( \beta + \frac{U}{2} \right) a'_{22} \right] \lambda^2 + \left[ b'_{12} + \left( \beta + \frac{U}{2} \right) b'_{22} \right] \lambda \mu + \left[ c'_{12} + \left( \beta + \frac{U}{2} \right) c'_{22} \right] \mu^2 \\
= \rho_* \tau_\nu W_H \lambda^2 + 2i\tau_* W_H \left[ \nu_* - \Gamma \rho_* \left( \beta + \frac{U}{2} \right) \right] \lambda \mu + 4\tau_* W_H \left[ \tau_* + \nu_* \left( \beta + \frac{U}{2} \right) \right] \mu^2 \\
= \frac{\tau_*}{2^{15} \pi^5 \sigma_*} (b_2 \lambda^2 + b_1 \lambda \mu + b_0 \mu^2). \]

Using the symmetry of the matrix in Equation (116), we have

\[
Q_{21}(\lambda, \mu) = \left[ a'_{21} + \left( \beta + \frac{U}{2} \right) a'_{12} \right] \lambda^2 + \left[ b'_{21} + \left( \beta + \frac{U}{2} \right) b'_{12} \right] \lambda \mu + \left[ c'_{21} + \left( \beta + \frac{U}{2} \right) c'_{12} \right] \mu^2 \\
= \left[ a'_{12} + \left( \beta + \frac{U}{2} \right) a'_{22} \right] \lambda^2 + \left[ b'_{12} + \left( \beta + \frac{U}{2} \right) b'_{22} \right] \lambda \mu + \left[ c'_{12} + \left( \beta + \frac{U}{2} \right) c'_{22} \right] \mu^2 \\
= Q_{12}(\lambda, \mu). \]

Finally:

\[
Q_{22}(\lambda, \mu) = a'_{22} \lambda^2 + b'_{22} \lambda \mu + c'_{22} \mu^2 \]
APPENDIX F: OVERVIEW OF THE CASE $W_{JJ} \neq 0$

In this appendix, we provide an overview for finding the characteristics of the Whitham modulation Equations (92)–(95) when $W_{JJ}$ and $W_{HH}$ are assumed to be nonvanishing. This provides justification for Equation (121). In a similar manner to Equation (96), we start by applying the implicit function theorem to $W_{J} = 0$, which yields a continuously differentiable function $h$ such that

$$J = h(H, U, \gamma, \beta).$$

Taking derivatives of $W_{J} = 0$ provides the relations:

$$\begin{align*}
\partial_H : h_H W_{JJ} &= -W_{HJ} \\
\partial_U : h_U W_{JJ} &= -W_{UJ} \\
\partial_{\gamma} : h_{\gamma} W_{JJ} &= -W_{\gamma J} \\
\partial_{\beta} : h_{\beta} W_{JJ} &= -W_{\beta J}.
\end{align*}$$

We now apply the chain rule to the $T$ and $X$ derivatives in the modulation equations in order to write them in terms of derivatives of the parameters. With $z = T, X$, the required derivatives are:

$$W_{JJ} \partial_z W_H = \{W_H, W_J\}_H, H_z + \{W_{\gamma}, W_J\}_H, J \gamma_z + \{W_U, W_J\}_H, U_z + \{W_{\beta}, W_J\}_H, J \beta_z$$

$$= -\sigma_s H_z + \gamma \gamma_z - \left( \tau_s + \frac{J}{2} \sigma_s + \Gamma \left( \beta + \frac{U}{2} \right) \right) U_z - (2 \tau_s + J \sigma_s + U \Gamma) \beta_z$$

$$W_{JJ} \partial_z W_U = \{W_U, W_J\}_H, H_z + \{W_U, W_J\}_J, J \gamma_z + \{W_U, W_J\}_U, U_z + \{W_U, W_J\}_J, J \beta_z$$

$$= -\left( \tau_s + \frac{J}{2} \sigma_s + \Gamma \left( \beta + \frac{U}{2} \right) \right) H_z + \left( -\frac{W_H M_{sJ}}{2} + J \Gamma - \left( \beta + \frac{U}{2} \right) \{W_{\gamma}, W_J\}_{\gamma, J} \right) \gamma_z$$

$$+ \left( -\frac{1}{4} W_H^2 - J \tau_s - \frac{J^2}{4} \sigma_s - \frac{1}{2} M_s W_{JJ} + W_{HH} M_{sJ} \left( \beta + \frac{U}{2} \right) \right) H_z$$

$$- J \Gamma \left( \beta + \frac{U}{2} \right) + \left( \beta + \frac{U}{2} \right)^2 \{W_{\gamma}, W_J\}_{\gamma, J} U_z$$

$$+ \left( -\frac{1}{2} W_H^2 - 2 J \tau_s - \frac{J^2}{2} \sigma_s - M_s W_{JJ} + W_{HH} M_{sJ} \left( \beta + U \right) - J \Gamma (\beta + U) \right)$$

$$+ U \left( \beta + \frac{U}{2} \right) \{W_{\gamma}, W_J\}_{\gamma, J} \beta_z$$

$$W_{JJ} \partial_z W = W_H W_{JJ} H_z + M_s W_{JJ} \gamma_z + W_U W_{JJ} U_z + W_{JJ} (J W_H - U M_s) \beta_z$$

$$W_{JJ} \partial_z W_{\gamma} = \{W_{\gamma}, W_J\}_H, H_z + \{W_{\gamma}, W_J\}_J, J \gamma_z + \{W_{\gamma}, W_J\}_U, U_z + \{W_{\gamma}, W_J\}_J, J \beta_z$$
\[= \Gamma H_z + \{W_{\gamma_s}, W_J\}_{\gamma_s,j}Y_{\gamma s} + \left(-\frac{W_H M_{sJ}}{2} + J\Gamma - \left(\beta + \frac{U}{2}\right)\{W_{\gamma_s}, W_J\}_{\gamma_s,j}\right) U_z \]
\[+ \left(-W_H M_{sJ} + J\Gamma - U\{W_{\gamma_s}, W_J\}_{\gamma_s,j}\right) \beta_z.\]

As in Equation (102), we write the modulation equations in the quasi-linear form:
\[\begin{pmatrix}
H_T \\
\gamma^*_T \\
U_T \\
\beta^*_T
\end{pmatrix} - a \begin{pmatrix}
H_X \\
\gamma^*_X \\
U_X \\
\beta^*_X
\end{pmatrix} = 0 \tag{F1}
\]

with
\[A = \begin{pmatrix}
0 & 0 & 0 & 1 \\
A_{21} & A_{22} & A_{23} & A_{24} \\
A_{31} & A_{32} & A_{33} & A_{34} \\
A_{41} & A_{42} & A_{43} & A_{44}
\end{pmatrix}, \quad a = \begin{pmatrix}
0 & U & 0 & 0 \\
U A_{21} & U A_{22} & U A_{23} - W_H W_{JJ} & U A_{24} \\
U A_{31} + a_{31} & U A_{32} + a_{32} & U A_{33} & U A_{34} + a_{34} \\
U A_{41} + 2\tau W_H & U A_{42} + W_H^2 M_{sJ} & U A_{43} + a_{43} & U A_{44} + a_{44}
\end{pmatrix}\]

and the coefficients
\[A_{21} = -\sigma_*\]
\[A_{22} = \Gamma\]
\[A_{23} = -\left(\tau_* + \frac{J}{2}\sigma_* + \Gamma\left(\beta + \frac{U}{2}\right)\right)\]
\[A_{24} = -(2\tau_* + J\sigma_* + U\Gamma)\]
\[A_{31} = -\left(\tau_* + \frac{J}{2}\sigma_* + \Gamma\left(\beta + \frac{U}{2}\right)\right)\]
\[A_{32} = -\frac{W_H M_{sJ}}{2} + \frac{J}{2}\Gamma - \left(\beta + \frac{U}{2}\right)\{W_{\gamma_s}, W_J\}_{\gamma_s,j}\]
\[A_{33} = \left(-\frac{1}{4}W_H^2 - J\tau_* - \frac{J^2}{4}\sigma_* - \frac{1}{2}M_* W_{JJ} + W_H M_{sJ}\left(\beta + \frac{U}{2}\right)\right)\]
\[-J\Gamma\left(\beta + \frac{U}{2}\right) + \left(\beta + \frac{U}{2}\right)^2\{W_{\gamma_s}, W_J\}_{\gamma_s,j}\]
\[A_{34} = \left(-\frac{1}{2}W_H^2 - 2J\tau_* - \frac{J^2}{2}\sigma_* - M_* W_{JJ} + W_H M_{sJ}(\beta + U) - J\Gamma(\beta + U)\right)\]
\[ + U \left( \beta + \frac{U}{2} \right) \{ W_{\gamma_s}, W_{j} \}_{\gamma_s, j} \]

\[ A_{41} = \Gamma W_H + \sigma_n M_s \]

\[ A_{42} = W_H \{ W_{\gamma_s}, W_{j} \}_{\gamma_s, j} - \Gamma M_s \]

\[ A_{43} = W_H \left( - \frac{W_H M_{sJ}}{2} + \frac{J}{2} \Gamma - \left( \beta + \frac{U}{2} \right) \{ W_{\gamma_s}, W_{j} \}_{\gamma_s, j} \right) + M_s \left( \tau_n + \frac{J}{2} \sigma_n + \Gamma \left( \beta + \frac{U}{2} \right) \right) \]

\[ A_{44} = W_H (- W_H M_{sJ} + J \Gamma - U \{ W_{\gamma_s}, W_{j} \}_{\gamma_s, j}) + M_s (2 \tau_n + J \sigma_n + U \Gamma) \]

\[ a_{31} = -W_H W_{JJ} \]

\[ a_{32} = -M_s W_{JJ} \]

\[ a_{34} = -W_{JJ} (JW_H - UM_s) \]

\[ a_{42} = M_s W_H W_{JJ} + W_{H}^2 \left( \frac{W_{H}}{2} + \frac{JW_{HJ}}{2} - M_{sJ} \left( \beta + \frac{U}{2} \right) \right) \]

\[ a_{44} = W_{H}^2 (W_H + JW_{HJ} - UM_{sJ}). \]

The equation for the characteristics is

\[ AX' - aT' = 0. \]

The matrices \( A, a \) satisfy Equation (106), since we can compute:

\[ \det(AX') = \frac{W_H W_{JJ}^2}{2^{10} \pi^4} X'^4 D \neq 0. \]  \hspace{1cm} (F2)

Moreover, we can follow the same procedure of applying the Schur determinant formula. The upper-left block matrix is

\[ P_{11} = \begin{pmatrix} 0 & -T' \\ -\sigma_n (X' - UT') & \Gamma (X' - UT') \end{pmatrix}, \]

which is only singular when \( X' = T' = 0 \) (from Equation (F2)), or when \( X' = UT' \). However, \( X' = UT' \) leads to the determinant calculation:

\[ \det(U AT' - aT') = W_{H}^2 W_{JJ}^2 T'^4, \]

which only vanishes when \( T' = 0 \), leading to the trivial solution \( X' = T' = 0 \). From here, the procedure of using the Schur determinant formula and manipulating the determinant calculation is the same as in Section . The end result is given in Equation (121).
