Abstract

We generalise Bray’s self-consistent screening approximation to describe the critical dynamics of the $\phi^4$ theory. In order to obtain the dynamical exponent $z$, we have to make an ansatz for the form of the scaling functions, which fortunately can be much constrained by general arguments. Numerical values of $z$ for $d = 3$, and $n = 1,...,10$ are obtained using two different ansätze, and differ by a very small amount. In particular, the value of $z \simeq 2.115$ obtained for the 3-d Ising model agrees well with recent Monte-Carlo simulations.

I. INTRODUCTION

Phase ordering kinetics, critical and low temperature dynamics of pure and random systems are the subject of active research. Of particular interest are the approximate methods to deal with non linear dynamical equations, which often amount to a self-consistent resummation of perturbation theory. A much debated case is the ‘mode-coupling’ approximation, used to describe liquids approaching their frozen (glass) phase. Interestingly, this mode-coupling approximation for systems without disorder can alternatively be seen as the exact equations for an associated disordered model of the spin-glass type. The simplest mode coupling approximation for the $\phi^4$ theory is however not very good. For example, it predicts for the static critical exponent $\eta$ the value $2 - \frac{d}{2}$ independently of the number $n$ of components of the field $\phi$. Furthermore, the underlying disordered model is not stable.

A better behaved resummation scheme is the “Self-Consistent Screening Approximation” (SCSA) introduced by Bray in the context of the static $\phi^4$ theory, and used in other contexts. It amounts to resumming self consistently all the diagrams appearing in the large-$n$ expansion, including those of order $\frac{1}{n}$. Again, this approximation becomes exact for a particular mean-field like spin-glass model, which turns out to be well defined for all temperatures and thus ensures that the approximation is well behaved.

The aim of the present paper is to generalize the SCSA equations to describe the dynamics of the $\phi^4$ theory at the critical point, and to predict a value for the dynamical exponent $z$.

In section we shall introduce the dynamical SCSA and the dynamical equations in their general form. From section and throughout the rest of the
paper we assume that time-translation invariance (TTI) and the fluctuation-dissipation theorem hold at least down to the critical point. Bray’s equations will be recovered as the static limit of our dynamical equations. The reliability of the SCSA is discussed quantitatively in the 0-dimensional static case.

In section [IV] we study the equations right at the critical temperature where dynamical scaling is supposed to hold. The full solution of these coupled equations, involving scaling functions gives in principle the dynamical exponent $z$ within the SCSA approximation. Unfortunately, as is often the case, these equations are very hard to solve, either analytically or even numerically. In section [V] and [VI] we thus propose two different ansätze for the scaling functions, which are however much constrained by general requirements. The second ansatz leads to the exact $O(\epsilon^2)$ result in the $\epsilon = 4 - d$ RG expansion of Halperin, Hohenberg and Ma. The numerical value of the exponent $z$ only very weakly depends on the chosen ansatz, and turns out to be quite close to the best available Monte-Carlo estimate for the Ising model in $d = 3$.

II. THE SELF CONSISTENT SCREENING APPROXIMATION

Let us consider the coarse-grained Hamiltonian density
\begin{equation}
\mathcal{H}[\phi(\vec{x})] = \frac{1}{2} (\nabla \phi(\vec{x}))^2 + \frac{\mu}{2} \phi^2(\vec{x}) - \frac{g}{8} \phi^4(\vec{x}),
\end{equation}
where $\phi(\vec{x})$ is an $n$ component field and $\vec{x}$ is the $d$ dimensional space variable. With $\phi^2(\vec{x})$ and $\phi^4(\vec{x})$ we indicate respectively $|\phi(\vec{x})|^2$ and $(|\phi(\vec{x})|^2)^2$. The coupling constant $g$ is negative and of order $n^{-1}$; $\mu$ is a (temperature dependent) mass term which vanishes at the mean-field transition point.

The partition function is
\[ Z = \int \mathcal{D}\vec{\varphi} e^{-\int d^d x \frac{H[\vec{\varphi}(\vec{x})]}{T}}, \quad (2.2) \]

In order to introduce the Self Consistent Screening Approximation one starts from a large-\(n\) expansion formalism. We re-write \(Z\) with a gaussian transformation introducing an auxiliary field \(\sigma\)

\[ Z = \int \mathcal{D}\sigma \mathcal{D}\vec{\varphi} e^{-\int d^d x \frac{H[\vec{\varphi}(\vec{x}), \sigma(\vec{x})]}{T}}, \quad (2.3) \]

\(H[\vec{\varphi}(\vec{x}), \sigma(\vec{x})]\) being now the Hamiltonian density of two coupled fields \(\vec{\varphi}(\vec{x})\) and \(\sigma(\vec{x})\).

\[ H[\sigma, \vec{\varphi}] = \frac{1}{2} (\nabla \vec{\varphi}(\vec{x}))^2 + \frac{\mu}{2} \vec{\varphi}^2(\vec{x}) + \frac{1}{2} \sigma^2(\vec{x}) - \frac{\sqrt{g}}{2} \sigma(\vec{x}) \vec{\varphi}^2(\vec{x}). \quad (2.4) \]

The SCSA amounts to consider the renormalization of the order 1/\(n\) diagrams in the Dyson expansion for the correlation functions of the two fields \(\vec{\varphi}(\vec{x})\) and \(\sigma(\vec{x})\). Using this resummation scheme Bray obtained interesting results for the static exponent \(\eta\) which describes the small momentum behaviour of the correlation functions. The static SCSA equations for \(\langle \vec{\varphi}(\vec{x})\vec{\varphi}(\vec{x}'')\rangle\) (plain line) and \(\langle \sigma(\vec{x})\sigma(\vec{x}'')\rangle\) (“dashed” line) are reported diagrammatically in figure 1. The bare quantities are indicated respectively with a thinner plain line and with a dashed line.

Our goal is to develop a dynamical generalization of this expansion for non-conserved Langevin dynamics, starting from the SCSA Hamiltonian. We thus obtain the following equations of motion for \(\vec{\varphi}(\vec{x}, t)\) and \(\sigma(\vec{x}, t)\):

\[ \dot{\vec{\varphi}}(\vec{x}, t) = -(\nabla^2 + \mu)\vec{\varphi}(\vec{x}, t) + \sqrt{g}\vec{\varphi}(\vec{x}, t)\sigma(\vec{x}, t) + \eta_{\vec{\varphi}}(\vec{x}, t) \quad (2.5) \]

\[ \dot{\sigma}(\vec{x}, t) = -\sigma(\vec{x}, t) + \frac{\sqrt{g}}{2} \vec{\varphi}^2(\vec{x}, t) + \eta_\sigma(\vec{x}, t). \quad (2.6) \]

with two independent thermal noises \(\eta_{\vec{\varphi}}, \eta_\sigma\).
Let us now consider the two-point functions

\[ G_{\vec{\varphi}}(\vec{x}, \vec{x}', t, t') = \left\langle \frac{\partial \vec{\varphi}(\vec{x}, t)}{\partial \eta(\vec{x}', t')} \right\rangle \quad (2.7) \]

\[ C_{\varphi}(\vec{x}, \vec{x}', t, t') = < \varphi(\vec{x}, t)\varphi(\vec{x}', t') >, \quad (2.8) \]

and the corresponding functions for the field \( \sigma \). The SCSA dynamical equations, which can be seen as a Mode-Coupling approximation on the set of equations (2.5-6) (see figure 2) then read:

\[ \Sigma_{\vec{\varphi}}(t_1, t_2) = n \frac{g}{2} \delta(t_1 - t_2) \int_0^{t_1} dt_3 C_{\varphi}(t_3, t_3) G^0_\sigma(t_1, t_3) + \]

\[ + g [G_{\varphi}(t_1, t_2)C_\sigma(t_1, t_2) + G_\sigma(t_1, t_2)C_{\varphi}(t_1, t_2)] \quad (2.9) \]

\[ \Sigma_\sigma(t_1, t_2) = ngG_{\varphi}(t_1, t_2)C_{\varphi}(t_1, t_2) \quad (2.10) \]

\[ D_{\varphi}(t_1, t_2) = 2T \delta(t_1 - t_2) + gC_{\varphi}(t_1, t_2)C_\sigma(t_1, t_2) \quad (2.11) \]

\[ D_\sigma(t_1, t_2) = 2T \delta(t_1 - t_2) + n \frac{g}{2} C^2_{\varphi}(t_1, t_2), \quad (2.12) \]

where we have dropped the space coordinates \( \vec{x} \) for clarity, and introduced the self-energies \( \Sigma \), defined as:

\[ G(t, t') = G^0(t, t') + \int_0^t dt_1 \int_{t_1}^{t_1'} dt_2 G^0(t, t_1)\Sigma(t_1, t_2)G(t_2, t'), \quad (2.13) \]

(the label \( ^0 \) refers to the bare quantity), and the ‘renormalized noises’ \( D \), defined as:

\[ C(t, t') = \int_0^t dt_1 \int_0^{t'} dt_2 G(t, t_1)D(t_1, t_2)G(t', t_2). \quad (2.14) \]

We shall limit ourselves to consider the above equations in a regime of stationary dynamics. That is to say that we will make use of the assumption
of time translational invariance (only differences of times matter), which allows one to show that the fluctuation dissipation theorem (FDT) is valid, i.e:

$$\theta(t-t') \frac{\partial C(t-t')}{\partial t'} = TG(t-t').$$ \hspace{1cm} (2.15)

Extensions of these methods to non stationary low temperature regime, where this theorem is violated, will be subject of further work. In the following, we shall set the energy scales by choosing $T = 1$, and vary the mass term $\mu$ to reach the critical point.

III. STATIC LIMIT

With these assumptions equations (2.12) reduce to only two coupled independent equations which have the simplest form in Fourier space

$$\Sigma_\varphi(k, \omega) = g \int [C_\sigma(k-k', \omega-\omega')G_\varphi(k', \omega') + C_\varphi(k-k', \omega-\omega')G_\sigma(k', \omega')]Dk'D\omega'$$

$$+ \frac{ng}{2}G_\sigma^0(k=0, \omega=0) \int C_\varphi(k', \omega')Dk'D\omega'$$

$$\Sigma_\sigma(k, \omega) = ng \int C_\varphi(k-k', \omega-\omega')G_\varphi(k', \omega')Dk'D\omega'.$$ \hspace{1cm} (3.1)

where $Dk' \equiv \frac{dk'}{(2\pi)^3}$ and $D\omega' \equiv \frac{d\omega'}{2\pi}$.

Using the fact that $C(k, t = 0) \equiv C(k)$ is equal to $G(k, \omega = 0)$ (from FDT and the Kramers-Kronig (KK) relations), and using again the KK relations, it is easy to check that for $\omega = 0$ one recovers exactly the static SCSA equations, namely

$$C_\varphi(k) = \frac{1}{\mu + k^2 - g \int Dk'C_\varphi(k-k')C_\sigma(k') - \frac{g^2}{2} \int Dk'C_\varphi(k')}$$

$$C_\sigma(k) = \frac{1}{1 - \frac{g}{2} \int Dk'C_\varphi(k-k')C_\varphi(k')}.$$ \hspace{1cm} (3.3)
In order to test the validity of this approximation, it is interesting to consider the case of zero spatial dimensions. Let us set \( n = 1 \) which is a bad case for the SCSA which should become more accurate the larger \( n \) is. We will compare equations (3.3) with the exact static correlation function which in zero dimension can be calculated analytically and is

\[
C_{\text{exact}} = -\frac{1}{\mu} + \frac{\mu}{g} - \frac{\mu K_{\frac{3}{4}}\left(\frac{\mu^2}{4g}\right)}{2gK_{\frac{1}{4}}\left(-\frac{\mu^2}{4g}\right)} - \frac{\mu K_{\frac{5}{4}}\left(\frac{\mu^2}{4g}\right)}{2gK_{\frac{1}{4}}\left(-\frac{\mu^2}{4g}\right)}, \tag{3.4}
\]

where \( K_{\alpha}(a) \) is the modified Bessel function of the second kind. Equations (3.3) give for \( C_{\vec{\phi}} \):

\[
C_{\text{scsa}} = \frac{1}{\left(\mu - n\frac{g}{2}C_{\text{scsa}} - g\frac{C_{\text{scsa}}}{1 - n\frac{g}{2}C_{\text{scsa}}}\right)} \tag{3.5}
\]

From plotting the relative difference of the two correlation functions versus the coupling (see figure 3) we can see that SCSA is quite close to the exact theory. In particular, the asymptotic behaviour in the \(|g| \to \infty\) limit of the two functions is

\[
\lim_{|g| \to \infty} \sqrt{|g|}C_{\text{scsa}} = 2(\sqrt{2} - 1) \quad \text{and} \quad \lim_{|g| \to \infty} \sqrt{|g|}C_{\text{exact}} = \frac{2\sqrt{2} \Gamma\left(\frac{3}{4}\right)}{\Gamma\left(\frac{1}{4}\right)}. \tag{3.6}
\]

For all \( g \), the relative difference is actually bounded by:

\[
\frac{|C_{\text{exact}} - C_{\text{scsa}}|}{C_{\text{exact}}} < 1 - \frac{\sqrt{-1 + \sqrt{2}} \Gamma\left(\frac{1}{4}\right)}{2 \Gamma\left(\frac{1}{4}\right)} = 0.0479... \tag{3.7}
\]

We can also compare the small – \( g \) expansions of the two theories which give

\[
C_{\text{exact}} = \frac{1}{\mu} \left(1 + \frac{3}{2\mu^2}g + \frac{21}{4\mu^4}g^2\right) \tag{3.8}
\]

\[
C_{\text{scsa}} = \frac{1}{\mu} \left(1 + \frac{3}{2\mu^2}g + \frac{5}{\mu}g^2\right) \tag{3.9}
\]
showing explicitly how the two theories differ already at order $g^2$. The self-consistent nature of the approximation however keeps the SCSA in good agreement with the exact theory even for large values of the coupling constant as remarked before.

It is instructive, in passing, to compare the SCSA with the simple Hartree $(n = \infty)$ resummation scheme, which is also the Gaussian variational result. One defines $F_H = \min \{F\}$ where

$$F = F_0 + \langle H - H_0 \rangle,$$  \hspace{1cm} (3.10)

with

$$F_0 = - \ln \int \mathcal{D} \bar{\phi} e^{-\frac{\mu \bar{\phi}^2}{2}} = - \ln \left( \frac{2\pi}{\bar{\mu}} \right) \ \ (3.11)$$

$$\langle H_0 \rangle = \frac{1}{2} \ \ (3.12)$$

$$\langle H \rangle = \int \mathcal{D} \bar{\phi} e^{-\frac{\mu \bar{\phi}^2}{2}} \left( \frac{\mu}{2} \bar{\phi}^2 - \frac{g}{8} \bar{\phi}^4 \right) = \left( \frac{\mu}{2\bar{\mu}} - \frac{3g}{8\bar{\mu}^2} \right) \ \ (3.13)$$

Minimising $F$ with respect to $\bar{\mu}$ we find

$$\mu_H = \frac{\mu + \sqrt{\mu^2 - 6g}}{2}, \ \ (3.14)$$

and consequently

$$\mathcal{C}_H = \langle \bar{\phi}^2 \rangle_{\mu_H} = \frac{2}{\mu + \sqrt{\mu^2 - 6g}} \ \ (3.15)$$

As can be seen from figure 3, the SCSA turns out to be fairly better than the Hartree variational approach (at least in this particular case of $n = 1$ and $d = 0$).
FIG. 3. Relative difference between the exact result and the Hartree ($C_H$) and the SCSA ($C_{scsa}$) approximations, in the case $n = 1, d = 0$. 
IV. CRITICAL DYNAMICS

We shall now work right at the critical point \( \mu_c \) such that the renormalised mass vanishes (therefore eliminating the ‘tadpole’ contribution in Eq. 2.9). We shall search for solutions under the general dynamic scaling form (valid in the small-\( k \) and small-\( \omega \) limit):

\[
G_{\vec{\varphi}}(k, \omega) = \frac{1}{k^\Delta} n_{\vec{\varphi}}(\frac{\omega}{k^z}) \quad \quad G_{\sigma}(k, \omega) = \frac{1}{k^\Delta'} n_{\sigma}(\frac{\omega}{k^z})
\]

\[
C_{\vec{\varphi}}(k, \omega) = \frac{2}{\omega k^\Delta} \text{Im} \left[ n_{\vec{\varphi}}(\frac{\omega}{k^z}) \right] \quad \quad C_{\sigma}(k, \omega) = \frac{2}{\omega k^\Delta'} \text{Im} \left[ n_{\sigma}(\frac{\omega}{k^z}) \right].
\] (4.1)

where we have defined \( \Delta = 2 - \eta \), and used FDT. Setting first \( \omega = 0 \), one finds by matching the momentum dependence of the left and right hand sides of (3.1-3.2) that:

\[
\Delta' = d - 2\Delta = d - 4 + 2\eta. \quad \quad \text{(4.2)}
\]

Note that in mean field, \( z = 2, \Delta = 2, \eta = 0 \) and \( \Delta' = 0 \). Identification of the prefactors yields:

\[
n_{\sigma}(0)n_{\vec{\varphi}}^2(0) = -\frac{2}{f(\eta, d)ng} \quad \quad \text{(4.3)}
\]

where

\[
f(\eta, d) = \frac{1}{(4\pi)^{d/2}} \frac{\Gamma[\Delta - \frac{d}{2}] \Gamma[\frac{d-\Delta}{2}]}{\Gamma[d - \Delta] \Gamma[\Delta^2/2]} \quad \quad \text{(4.4)}
\]

and an extra equation fixing \( \eta \) as a function of \( d \) and \( n \), which we do not write explicitly.

Now let us consider the other case where \( k = 0 \) and \( \omega > 0 \) (but small). Taking the imaginary part of (3.1-3.2), one obtains:
\[
\text{Im} [\Sigma_\varphi(0, \omega)] = \frac{S \omega}{m n \varphi(0)} \int q^{\Delta - 1} dq ds \frac{\text{Im} [f_{\varphi}((\omega - s)/q^z)] \text{Im} [f_{\sigma}(s/q^z)]}{s(\omega - s)} \tag{4.5}
\]

\[
\text{Im} [\Sigma_\sigma(0, \omega)] = \frac{S}{n_\sigma(0)} \int q^{\Delta' - 1} dq ds \frac{\text{Im} [f_{\varphi}((\omega - s)/q^z)] \text{Im} [f_{\sigma}(s/q^z)]}{s}, \tag{4.6}
\]

where \( f_{\varphi,\sigma}(x) = n_{\varphi,\sigma}(x)/n_{\varphi,\sigma}(0) \). We also defined

\[
S = \frac{2ng\Omega_d}{(2\pi)^{(d+1)/2} n_{\varphi}(0)n_\sigma(0) \equiv \frac{4\Omega_d}{f(\eta, d)(2\pi)^{(d+1)}}} \tag{4.7}
\]

In general the scaling functions can be written

\[
\text{Im} [f_{\varphi}(x)] = A \tilde{f}_{\varphi}(ax) \tag{4.8}
\]

\[
\text{Im} [f_{\sigma}(x)] = A' \tilde{f}_{\sigma}(a'x),
\]

with by convention \( \lim_{u \to \infty} u^{\Delta/z} \tilde{f}_{\varphi}(u) = 1 \) and \( \lim_{u \to \infty} u^{\Delta'/z} \tilde{f}_{\sigma}(u) = 1 \). This asymptotic behaviour is required for the \( k \to 0 \) limit to be well defined, if (4.1) is correct. Furthermore, the small-\( \omega \) behaviour of the imaginary part of the response function is expected to be regular for \( k \) finite, and hence \( \tilde{f}(u) \propto u \) for \( u \to 0 \). \( A, A' \) are coefficients setting the scale of the imaginary part of the response function while \( a, a' \) are coefficients setting the frequency scales.

Using the fact that the imaginary and real part of the response function are power-laws at large frequencies, which imply that their ratio is \( \tan \left( \frac{\pi \Delta}{2z} \right) \) (resp. \( \tan \left( \frac{\pi \Delta'}{2z} \right) \)), one finds that:

\[
\frac{a^{\Delta/z}}{A} \sin^2 \left( \frac{\pi \Delta}{2z} \right) = \frac{S}{nz} \int_0^\infty \frac{dx}{x^{1+\Delta/z}} \int_{-\infty}^\infty \frac{du}{u(1 - u)} \text{Im} [f_{\varphi}(x(1 - u))] \text{Im} [f_{\sigma}(xu)]
\]

\[
\frac{a'^{\Delta'/z}}{A'} \sin^2 \left( \frac{\pi \Delta'}{2z} \right) = \frac{S}{z} \int_0^\infty \frac{dx}{x^{1+\Delta'/z}} \int_{-\infty}^\infty \frac{du}{u} \text{Im} [f_{\varphi}(x(1 - u))] \text{Im} [f_{\sigma}(xu)] \tag{4.9}
\]

It is easy to show that these equations actually only depend on the value of the ratio of frequency scales \( y = \frac{a'}{a} \). The coefficient \( A \) can be fixed using the
KK relation, since the involved integral converges, which means that the small-
$k$-behaviour of the real part of the correlation function is fully determined by
the imaginary part in the scaling region $\omega, k \to 0$. Hence:

$$1 = \frac{A}{\pi} \int_{-\infty}^{\infty} dx \frac{\hat{f}_\varphi(x)}{x}. \quad (4.10)$$

The corresponding integral for $\hat{f}_\sigma$ does not converge for large $x$, meaning that
the non-scaling region is needed to saturate the sum-rule. Hence, we must use
another relation to fix $A'$, which we choose to be the small-$\omega$ expansion of Eq.
(4.6).

Thus, if the functions $\hat{f}_\varphi, \hat{f}_\sigma$ were known, we would have four equations
to fix four constants: $A, A', y$, and, of course, the dynamical exponent $z$, in
terms of $d$ and $n$. $\hat{f}_\varphi, \hat{f}_\sigma$ are in principle also fixed by the full equations for
arbitrary $\frac{\omega}{k^\alpha}$. However, as in other similar cases, these equations are very hard
to solve, either analytically or numerically. We will thus propose ansätze for
these functions, which have to satisfy the above general requirements. Note
that once $A, A', a, a'$ have been pulled out, the only freedom is in the shape of
these functions. We shall thus work with two such ansätze, which will turn
out to give very similar answers for $z$. This was also the case in the context of
the KPZ equation.

V. ANSATZ 1

The simplest ansatz one can think of, which generalizes the mean field
shape:

$$\hat{f}_\varphi(x) = \frac{x}{(1 + x^2)} . \quad (5.1)$$

13
reads:

\[\tilde{f}_\psi(x) = \frac{x}{(1 + x^2)^\alpha}, \quad \text{(5.2)}\]
\[\tilde{f}_\sigma(x) = \frac{x}{(1 + x^2)\alpha'}, \quad \text{(5.3)}\]

where we have set

\[\alpha = \frac{\Delta + z}{2z}, \quad \text{(5.4)}\]
\[\alpha' = \frac{\Delta' + z}{2z}. \quad \text{(5.5)}\]

(Note that \(\alpha = 1\) in mean field). These functions have indeed the correct asymptotic behaviours; they go linearly to zero for small values of the argument and behave as power laws \(\tilde{f}_\psi(x) \simeq x^{-\Delta}\) and \(\tilde{f}_\sigma(x) \simeq x^{-\Delta'}\) in the large-\(x\) limit.

We can now use (4.10) to determine \(A\)

\[A = \sqrt{\pi \frac{\Gamma[\alpha]}{\Gamma\left[\alpha - \frac{1}{2}\right]}}. \quad \text{(5.6)}\]

The small-\(\omega\) expansion of \(\text{Im} \Sigma_\sigma(k, \omega)\) can be matched with that of the right hand side of Eq.(4.6) leading to the following equation

\[y = -\frac{2A^2}{A' f(\eta, d)(2\pi)^{d+1}} \int_{-\infty}^{\infty} dq \int_{-\infty}^{\infty} dt \left[ \frac{1}{1 - q} \right] \frac{1}{(1 + t^2)^\alpha \left(1 + \left(\frac{|q|t}{1 - q^2}\right)^2\right)^\alpha} \]

\[\int_{-\infty}^{\infty} du \left[ \frac{1}{u^{2 - \alpha}} \right] \left[ \frac{1}{u^{2 - \alpha'}} \right] \left[ \frac{1}{u^{2 - y^2}} \right] \quad \text{(5.7)}\]

After some algebraic manipulations we obtain for the last three equations:

\[\sin^2 \left(\frac{\pi \Delta}{2z}\right) = -\frac{A^2 A' y S}{2nz^2} B \left[ 1 - \frac{\Delta}{2z}, \frac{d}{2z} \right] \int_{-\infty}^{\infty} \frac{du}{|u|^{2 - \Delta}} \left[ \alpha', 1 - \frac{\Delta}{2z}, \alpha + \alpha', 1 - y^2 \left(\frac{1 - u^2}{u^2}\right) \right] \quad \text{(5.8)}\]
\[
\sin^2 \left( \frac{\pi \Delta'}{2z} \right) = -\frac{A^2 A' S}{2z} y^{-\Delta'} B \left[ 1 - \frac{\Delta'}{2z}, \frac{d}{2z} \right] \\
\int_{-\infty}^{\infty} \frac{udu}{|u|^{2-\Delta'}} F \left[ \alpha, 1 - \frac{\Delta'}{2z}, 2\alpha, \frac{2u - 1}{u^2} \right]
\]

(5.9)

\[
y = \pi \frac{A^2 S}{z A' \Omega_d} B \left[ \frac{1}{2}, 2\alpha - \frac{1}{2} \right] \\
\int_{0}^{\infty} dq d^{d-2-\Delta} \int_{|q|^{2z}}^{1+q^{2z}} \frac{dx}{x^{\Delta + \frac{1}{2} \Delta'} x^{\frac{1}{2} - 2\alpha}} F \left[ \alpha, \frac{1}{2}, 2\alpha, 1 - \frac{q^{2z}}{x} \right].
\]

(5.10)

where \(B[a,b]\) and \(F[a,b,c,x]\) are the Euler Beta and Hypergeometric functions and where the last equation (5.10) was written for the special case \(d = 3\) which we shall consider below. We can solve analytically Eqs. (5.7,5.8,5.9) at order \(\epsilon^2\) to compare with the exact RG treatment of [10]. At lowest order we obtain:

\[
c = \frac{8 \ln 2}{\pi} \arctan \frac{1 - y^2}{\sqrt{1 - y^2}} - 1 \quad (5.11)
\]

\[
A' = -\frac{\pi \epsilon}{4} \quad (5.12)
\]

\[
y = \frac{4 \ln 2}{\pi} \quad (5.13)
\]

where we have defined, following [4],

\[
z = 2 + c\eta. \quad (5.14)
\]

The order \(O(\epsilon^2)\) RG result reads, \(c = 6 \ln \frac{4}{3} - 1 = 0.7261\). The form (5.14) means that to lowest order \(z\) depends on \(n\) only through the static exponent \(\eta\). On the other hand, Eqs. (5.13) give

\[
c = 0.8376, \quad (5.15)
\]

in slight disagreement with the exact result. This comes from the fact that while our ansatz for \(\tilde{f}_{\vec{\varphi}}\) is exact in the limit \(\epsilon \to 0\), the corresponding ansatz
for $\tilde{f}_\sigma$ is already wrong at lowest order since it does not satisfy Eq. (4.6). In our second ansatz, we thus keep the same shape for $\tilde{f}_\varphi$, but choose for $\tilde{f}_\sigma$ a form which is exact when $\epsilon \to 0$.

**VI. ANSATZ 2**

Knowing the mean field form for $f_\varphi(x)$ we can, at lowest order in $\epsilon$, write for $\text{Im}[f_\sigma(x)]$

$$\text{Im} f_\sigma(x) = 2^{d-4} f(\eta, d) \left( \frac{2\pi}{d} \right)^d \Gamma[2 - \frac{d}{2}] \text{Im} \left[ \frac{1}{\xi(x)} \right]$$

(6.1)

where

$$\xi(x) = 1 - \frac{\epsilon}{2} \int_0^1 dt \log \left[ 1 - t^2 - 2i\epsilon(1 - t) \right].$$

(6.2)

It is then straightforward to generalize $\text{Im}[f_\sigma(x)]$ to general dimensions as:

$$\tilde{f}_\sigma \propto \text{Im} \left[ (2 - i\epsilon)^{1 - \frac{\Delta'}{2}} - (1 - i\epsilon)^{1 - \frac{\Delta'}{2}} \right]$$

(6.3)

with a prefactor ensuring that the coefficient of $x^{-\frac{\Delta'}{2}}$ for large $x$ is unity. Eq. (5.8) is now replaced by:

$$\sin^2 \left( \frac{\pi \Delta}{2z} \right) = \frac{A^2 A' S b}{nz} \int_0^\infty \frac{dr}{r^2} \int_{-\infty}^{\infty} du \frac{\text{Im} \left[ (2 - i \frac{\pi}{2 \ln 2} (yru)^{1 - \frac{\Delta'}{2}} - (1 - i \frac{\pi}{2 \ln 2} (yru))^{1 - \frac{\Delta'}{2}} \right]}{u \left[ 1 + r^2(1 - u)^2 \right]^\alpha}.$$

(6.4)

where now $b$ is given by:

$$b = \frac{2 \ln 2}{\pi \left( 2 - \frac{\Delta'}{2} - 1 \right) \left( \frac{\Delta'}{2} - 1 \right)}.$$

(6.5)

We finally obtain a set of equations for $z$ of the same kind as (5.8-5.10) but which now exact up to $O(\epsilon^2)$, as we have checked directly.
VII. NUMERICAL RESULTS

We solved numerically both sets of equations in $d = 3$ for $n = 1, \ldots, 10$. We used the values of $\eta(d = 3, n)$ that can be derived from the formula reported in [5]. The values obtained for $z$ are reported in the following table.

| $n$ | $z$ (ansatz 1) | $z$ (ansatz 2) |
|-----|----------------|----------------|
| 1   | 2.119          | 2.113          |
| 2   | 2.071          | 2.069          |
| 3   | 2.050          | 2.049          |
| 4   | 2.038          | 2.038          |
| 5   | 2.031          | 2.031          |
| 6   | 2.0258         | 2.0258         |
| 7   | 2.0223         | 2.0222         |
| 8   | 2.0196         | 2.0195         |
| 9   | 2.0174         | 2.0174         |
| 10  | 2.0157         | 2.0157         |

As it was hoped, the results are fairly independent from the ansatz used, which is more and more true for large $n$. The result for $n = 1$ is rather close to the best Monte-Carlo estimate of ref. [12], which gives $z = 2.09 \pm 0.02$. Let us note however that the SCSA overestimates significantly $\eta$ in $d = 3$.

In figure (4) we compare the two different choices for the scaling function $f_\sigma(x)$ with their relative values of the parameters $y$, $A'$ and $z$, and in the case $n = 1, d = 3$. We notice that the constraints for small $x$ and large $x$ restrict very much the freedom on the shape of this function.

Finally, a linear regression of our results for $n = 1 - 10$ gives $z \simeq 2 + c\eta$ with $c = 0.64$, which is lower that the $O(\epsilon^2)$ result, but larger that the exact result for $d = 3, n \to \infty$, i.e. $c = \frac{1}{2}$.

VIII. CONCLUSIONS

The aim of this paper was extend the static Self-Consistent screening approximation to dynamics, in particular to calculate the properties of the critical dynamics of the $\phi^4$ model. Although the resulting equations cannot be fully solved, a much constrained ansatz leads to a value of the exponent $z$ in rather good agreement with Monte-Carlo data.

Our work was originally inspired by glassy dynamics: the SCSA equations actually describe in exactly the dynamics of some mean-field spin glass like models. It would be interesting to study these equations in the low temperature phase, where dynamics becomes non stationary (aging) and FDT is lost. For $\phi^4$ models, this corresponds to a coarsening regime. It would be interesting to know whether the SCSA equations describe properly this regime, and can compete with other approximation schemes.
Acknowledgments It is a pleasure for us to thank A. Barrat, A. Bray, L.F. Cugliandolo, J. Kurchan, E. Maglione, M. Mézard, R. Monasson, G. Parisi and P. Ranieri for very instructive discussions.
