Energy characteristics of subordination chains

Alexander Vasil'ev

Abstract. We consider subordination chains of simply connected domains with smooth boundaries in the complex plane. Such chains admit Hamiltonian and Lagrangian interpretations through the Löwner-Kufarev evolution equations. The action functional is constructed and its time variation is obtained. It represents the infinitesimal version of the action of the Virasoro-Bott group over the space of analytic univalent functions.

1. Introduction

Many physical processes may be interpreted as expanding dynamical systems of domains in the complex plane \( \mathbb{C} \) or in the Riemann sphere \( \hat{\mathbb{C}} \). This leads to the study of time-parameter Löwner subordination chains. In particular, we are interested in Löwner chains of simply connected univalent domains with smooth \( (C^\infty) \) boundaries. There exists a canonical identification of the space of such domains (under certain conformal normalization) with the infinite dimensional Kähler manifold whose central extension is the Virasoro-Bott group. A Löwner subordination chain \( \Omega(t) \) is described by time-dependent family of conformal maps \( z = f(\zeta,t) \) from the unit disk \( \mathbb{U} \) onto \( \Omega(t) \), normalized by \( f(\zeta,t) = a_1(t)\zeta + a_2(t)\zeta^2 + \ldots \), \( a_1(t) > 0 \). After 1923 seminal Löwner’s paper [15] a fundamental contribution to the theory of Löwner chains has been made by Pommerenke [18, 19] who described governing evolution equations in partial and ordinary derivatives, known now as the Löwner-Kufarev equations due to Kufarev’s work [13]. A particular case of subordination dynamics is presented by the Laplace growth evolution (or Hele-Shaw advancing evolution) consisting of the Dirichlet problem for a harmonic potential where the boundary of the phase domain is unknown \textit{a priori} (free boundary), and, in fact, is defined by the normality of its motion. (see, e.g., [8, 21, 25]). The aim of our paper is to give a Hamiltonian and Lagrangian descriptions of the subordination evolution. In particular, we discuss the relations between the Löwner-Kufarev equations in partial and ordinary derivatives, construct the action functional, obtain its time variation. This variation represents the infinitesimal version of the action of the Virasoro-Bott group over the space of analytic univalent functions.

2. Hamiltonian formulation of the subordination evolution

The parametric method emerged more than 80 years ago in the celebrated paper by Löwner [15] who studied a time-parameter semigroup of conformal one-slit maps of the unit disk $U$ coming then at an evolution equation called after him. His main achievement was an infinitesimal description of a semi-flow of such maps by the Schwarz kernel that led him to the Löwner equation. This crucial result was generalized, then, in several ways (see [19] and the references therein).

A time-parameter family $\Omega(t)$ of simply connected hyperbolic univalent domains forms a subordination chain in the complex plane $\mathbb{C}$, for $0 \leq t < \tau$ (where $\tau$ may be $\infty$), if $\Omega(t) \subset \Omega(s)$, $\Omega(t) \neq \Omega(s)$, whenever $t < s$. We suppose that the origin is an interior point of the kernel of $\{\Omega(t)\}_{t=0}^{\tau}$, and the boundaries $\partial \Omega(t)$ are smooth ($C^\infty$). Let us normalize the growth of the evolution of this subordination chain by the conformal radius of $\Omega(t)$ with respect to the origin to be $e^t$. By the Riemann Mapping Theorem we construct a subordination chain of mappings $f(\zeta,t)$, $\zeta \in U$, where each function $f(\zeta,t) = e^t \zeta + a_2(t)\zeta^2 + \ldots$ is a holomorphic univalent map of $U$ onto $\Omega(t)$ for every fixed $t$.

Pommerenke’s result [18, 19] says that given a subordination chain of domains $\Omega(t)$ defined for $t \in [0,\tau)$, there exists an analytic regular function $p(\zeta,t)$ such that $\Re p(\zeta,t) > 0$ and

$$\frac{\partial f(\zeta,t)}{\partial t} = \zeta \frac{\partial f(\zeta,t)}{\partial \zeta} p(\zeta,t),$$

for $\zeta \in U$ and for almost all $t \in [0,\tau)$. The equation (1) is called the Löwner-Kufarev equation due to two seminal papers by Löwner [15] with

$$p(\zeta,t) = \frac{e^{iu(t)} + \zeta}{e^{iu(t)} - \zeta},$$

where $u(t)$ is a continuous function regarding to $t \in [0,\tau)$, and by Kufarev [13] in general case, where this equation appeared for the first time.

In [26], the case of smooth boundaries $\partial \Omega(t)$, being embedded into the class of quasidisks, has been proved to admit a specific integral form of the function $p(\zeta,t)$ as

$$p(\zeta,t) = 1 + \frac{\zeta}{2\pi i} \int_{S^1 = \partial U} \frac{\nu(\omega,t)}{\omega(\omega - \zeta)} d\omega,$$

for almost all $t \in [0,\tau]$, where the function $\nu(\omega,t)$ belongs to the Lie algebra $\text{Vect} \ S^1$ of the vector fields on the unit circle $S^1$, with the the Poisson - Lie bracket given by

$$[\nu_1, \nu_2] = \nu_1 \nu_2' - \nu_2 \nu_1',$$

where the derivatives are taken with respect to the angle variable of $S^1$. Comparing with the Herglotz representation

$$p(\zeta,t) = \zeta \int_{S^1} \frac{\omega + \zeta}{\omega - \zeta} d\mu(\omega,t),$$
for the family of Herglotz measures normalized as \( \int_{S^1} d\mu(\omega, t) = 1 \), we deduce that
\[
\rho(e^{i\theta}, t) \equiv \frac{1}{4\pi} \psi(e^{i\theta}, t).
\]
From the other side, \( \Re \psi(e^{i\theta}, t) = 2\pi \rho(e^{i\theta}, t) \) and the real-valued function \( \rho(e^{i\theta}, t) \) is non-negative for almost all \( t \in [0, \tau] \).

To arrive at the Hamiltonian interpretation of subordination dynamics, let us rewrite equation (1) in the form
\[
\frac{\partial f'(\zeta, t)}{\partial t} = \frac{\partial H(\zeta, f', t)}{\partial \zeta},
\]
where \( H(\zeta, f', t) = \zeta f'(.t) \) and the derivative \( f' \) is taken with respect to the complex variable \( \zeta \). Interpreting the function \( H(\zeta, f', t) \) as a Hamiltonian we must write
\[
\frac{\partial \zeta}{\partial t} = -\frac{\partial H(\zeta, f', t)}{\partial f'} = -\zeta \rho(\zeta, t),
\]
formally yet. Equations (3) and (4) constitute the conjugate pair of Hamilton’s relations, however this requires some additional clearance to give sense to the equation (2). This equation is just the Löwner-Kufarev equation in ordinary derivatives \( \dot{\zeta} = -\zeta \rho(\zeta, t) \).

The equation (1) represents a growing evolution of simply connected domains. Let us consider the reverse process. Given an initial domain \( \Omega(0) \equiv \Omega_0 \) (and therefore, the initial mapping \( f(\zeta, 0) \equiv f_0(\zeta) \)), and a function \( \rho(\zeta, t) \) with positive real part normalized by \( \rho(\zeta, t) = 1 + p_1 \zeta + \ldots \), we solve the equation (1) and ask whether the solution \( f(\zeta, t) \) represents a subordination chain of simply connected domains. The initial condition \( f(\zeta, 0) = f_0(\zeta) \) is not given on the characteristics of the partial differential equation (1), hence the solution exists and is unique.

Assuming \( s \) as a parameter along the characteristics we have
\[
\frac{dt}{ds} = 1, \quad \frac{d\zeta}{ds} = -\zeta \rho(\zeta, t), \quad \frac{df}{ds} = 0,
\]
with the initial conditions \( t(0) = 0, \zeta(0) = z, f(\zeta, 0) = f_0(\zeta) \), where \( z \) is in \( U \). Obviously, \( t = s \). We still need to give sense to this formalism because the domain of \( \zeta \) is the entire unit disk, however the solutions to the second equation of the characteristic system range within the unit disk but do not fill it. Therefore, introducing another letter \( w \) in order to distinguish the function \( w(z, t) \) from the variable \( \zeta \), we arrive at the Cauchy problem for the Löwner-Kufarev equation in ordinary derivatives for a function \( \zeta = w(z, t) \)
\[
\frac{dw}{dt} = -wp(w, t),
\]
with the initial condition \( w(z, 0) = z \). The equation (5) is the non-trivial characteristic equation for (1). Unfortunately, this approach requires the extension of \( f_0(w^{-1}(\zeta, t)) \) into \( U \) \( (w^{-1} \) means the inverse function) because the solution to (1) is the function \( f(\zeta, t) \) given as \( f_0(w^{-1}(\zeta, t)) \), where \( \zeta = w(z, s) \) is a solution of the initial value problem for the characteristic equation (5) (or (1)) that maps \( U \) into \( U \). Therefore, the solution of the initial value problem for the equation (1) may be non-univalent.

Let \( A \) stand for the usual class of all univalent holomorphic functions \( f(z) = z + a_2 z^2 + \ldots \) in the unit disk. Solutions to the equation (5) are regular univalent
functions \( w(z,t) = e^{-t}z + a_2(t)z^2 + \ldots \) in the unit disk that map \( U \) into itself. Conversely, every function from the class \( A \) can be represented by the limit

\[
f(z) = \lim_{t \to \infty} e^t w(z,t),
\]

where there exists a function \( p(z,t) \) with positive real part for almost all \( t \geq 0 \), such that \( w(z,t) \) is a solution to the equation (4) (see [19] pages 159–163). Each function \( p(z,t) \) generates a unique function from the class \( A \). The reciprocal statement is not true. In general, a function \( f \in A \) can be determined by different functions \( p \).

From [19, page 163] it follows that we can guarantee the univalence of the solutions to the Löwner-Kufarev equation in partial derivatives ([11]) assuming the initial condition \( f_0(\zeta) \) given by the limit (6) with the function \( p(\cdot, t) \) chosen to be the same in the equations (1) and (5). Originally, these arguments have been made by Prokhorov and the author in [20]. We remark also that an analogous Hamiltonian \( H \) one may also find in [4].

The Hamiltonian \( H \) is linear with respect to the variable \( f' \), therefore, the Hamiltonian dynamics which is generated by \( H \) is trivial and the velocity is constant. In [20] we studied another Hamiltonian system for a finite number of the coefficients of the function \( w(z,t) \) generated by the equation (5). It turns out that the Hamiltonian system generated by the coefficients is Liouville partially integrable and the first integrals were obtained and were proved to possess a contact structure. However, the Hamiltonian was again linear with respect to the conjugate system, and we have both systems accelerationless. In order to describe a non-trivial motion we proceed with the Lagrangian formulation.

3. Lagrangian formulation of the subordination evolution

Let us consider a subordination chain \( \{\Omega(t)\}_{t=0}^T, 0 \in \Omega(t) \), and the time-parameter family of the real-valued Green functions \( G(z,t) \) of \( \Omega(t) \) with the logarithmic singularity at 0. If \( z = f(\zeta,t) \) is the Riemann map from the unit disk \( U \) onto \( \Omega(t) \), \( f'(0,t) = e^t \), then \( G(z,t) = -\log|f^{-1}(z,t)| \). The unit normal vector \( n \) to \( \partial \Omega(t) \) in the outward direction can be written as

\[
n = \frac{\zeta f'(\zeta,t)}{|f'(\zeta,t)|}, \quad |\zeta| = 1.
\]

Therefore, the normal velocity \( v_n \) of the boundary \( \partial \Omega(t) \) at the point \( f(e^{i\theta},t) \) may be expressed as

\[
v_n = \Re \int f \frac{e^{i\theta} f'}{|f'|} - |f'| \Re \frac{f'}{e^{i\theta} f'} = |f'| \rho(e^{i\theta},t),
\]

where the function \( \rho(e^{i\theta},t) \) was defined in the preceding section. Thus, \( \rho(e^{i\theta},t) = v_n |\nabla G| \).

The easiest Lagrangian is given by the Dirichlet integral

\[
\iint_{D} |\nabla G|^2 \sigma_z,
\]

where \( d\sigma_z = |dz \wedge d\bar{z}| \), locally for any measurable set \( D \subset \Omega(t) \setminus \{0\} \). However, this functional cannot be defined globally in \( \Omega(t) \setminus \{0\} \) because of the parabolic singularity at the origin. To overcome this obstacle we define the energy represented
by this Lagrangian in the following way. Let $\Omega_\epsilon(t) = \Omega(t) \setminus \{z : |z| \leq \epsilon\}$ for a sufficiently small $\epsilon$, $U_\epsilon = \{\zeta : \epsilon < |\zeta| < 1\}$. Then the finite limit

$$
E = \lim_{\epsilon \to 0} \left\{ \int_{\Omega_\epsilon(t)} |\nabla G|^2 d\sigma_\epsilon + 2\pi \log \epsilon \right\}
$$

exists. Applying the conformal map $z = f(\zeta, t)$ and changing variables we arrive at the representation of the energy

$$
E = E[f] = 2\pi \log |f'(0, t)| = 2\pi t,
$$

just by the capacity (or the conformal radius in this case) of $\partial \Omega(t)$. In other words, $E$ represents the classical action for the Lagrangian defined by the Dirichlet integral. This interpretation allows us to get less trivial Lagrangian description of subordination dynamics, that in particular, emerges in the Liouville part of the CFT

\[ \text{[17][22].} \]

The classical field theory studies the extremum of the action functional, and its critical value is called the classical action. The critical point $\phi^*$ satisfies Hamilton’s principle (or the principle of the least action), i.e., $\delta S[\phi^*] = 0$, which is the Euler-Lagrange equation for the variational problem defined by the action functional $S[\phi]$. For the action given by the Dirichlet integral the classical action is achieved for the harmonic $\phi^*$ and the principle of the least action leads to the Laplacian equation $\Delta \phi = 0$ as above. The Liouville action plays a key role in two-dimensional gravity and leads to the Liouville equation, a solution of which is the Poincaré metric of the constant negative curvature. This conformal metric is of a particular interest, because no flat metric satisfies the Einstein Field Equation. The conformal symmetry of CFT is generated by its energy-momentum tensor $T$ whose mode expansion is expressed in terms of the operators satisfying the commutation relations of the Virasoro algebra. The $(2,0)$-component of the energy-momentum tensor in the Liouville theory is given by the expression $T_{\zeta \bar{\zeta}} = \varphi_{zz} - \frac{1}{2} \varphi_z^2$ that leads to the classical Schwarz result $T_{\bar{\zeta}} = S_f(\zeta)$ with the Schwarzian derivative $S_f$ where $f$ is the ratio of two linearly independent solutions to the Fuchsian equation $w'' + \frac{1}{2} T_{\zeta \bar{\zeta}} w = 0$.

In the case of subordination chains our starting point will be a Riemannian metric $ds^2 = e^{\varphi(z)} |dz|^2$. In the case of the Liouville theory, the real-valued potential $\varphi$ satisfies the Liouville equation $\varphi_{z\bar{\zeta}} = \frac{1}{2} e^\varphi$ (generally, with certain prescribed asymptotics which guarantee the uniqueness). Geometrically, this means that the conformal metric $ds^2$ has constant negative curvature -1 on the underlying Riemann surface corresponding to prescribed singularities. Let us consider the complex Green function $W(z, t)$ whose real part is $G(z, t) = |f^{-1}(z, t)|$, $z \in \Omega(t) \setminus 0$, as before. We have the representation $W(z, t) = -\log z + w_0(z, t)$, where $w_0(z, t)$ is an analytic regular function in $\Omega(t)$. Because of the conformal invariance of the Green function we have the superposition

$$
(W \circ f)(\zeta, t) = -\log \zeta,
$$

and the conformally invariant complex velocity field is just $W'(z, t) = -\frac{1}{f'}(z, t)$, where $\zeta = f^{-1}(z, t)$ is the inverse to our parametric function $f$ and prime means the complex derivative. Rewriting this relation we get

$$
(W'(z, t) \, dz)^2 = \frac{d\zeta^2}{\zeta^2}.
$$
The velocity field is the conjugation of \((-W')\). In other words, the velocity field is directed along the trajectories of the quadratic differential in the left-hand side of \(\mathcal{S}\) for each fixed moment \(t\). The equality \(\mathcal{S}\) implies that the boundary \(\partial\Omega(t)\) is the orthogonal trajectory of the differential \((W'(z, t) \, dz)^2\) with a double pole at the origin. The dependence on \(t\) yields that the trajectory structure of this differential changes in time, and in general, the stream lines are not inherited in time. These lines are geodesic in the conformal metric \(|W'(z, t)|^2|dz|^2\) generated by this differential. Let us use the conformal logarithmic metric generated by \(\mathcal{S}\)

\[
ds^2 = \frac{|f^{-1}'|^2}{|f^{-1}|^2}|dz|^2 = |W'|^2|dz|^2,
\]

which is intrinsically flat. Unlike the Poincaré metric, the hyperbolic boundary is not singular for the logarithmic metric whereas the origin is. But it is a parabolic singularity which can be easily regularized. The density of this metric satisfies the usual Laplacian equation \(\phi_{zz} = 0\) in \(\Omega(t) \setminus \{0\}\), where \(\phi(z) = \log \frac{|f^{-1}'|^2}{|f^{-1}|^2}\). The function \(\phi\) possesses the asymptotics \(\phi \sim \log \frac{1}{|z|^2}\), \(|\phi_z| \sim \frac{1}{|z|^2}\) as \(z \to 0\), therefore, the finite limit

\[
S = S[\phi] = \lim_{\varepsilon \to 0} \int_{\chi_{\Omega(t)}|z| > \varepsilon} \int |\phi_z|^2 d\sigma_z + 2\pi \log \varepsilon
\]

exists and is called the logarithmic action.

**Lemma 1.** The Euler-Lagrange equation for the variational problem for the logarithmic action \(S[\phi]\) is the Laplacian equation \(\Delta \phi = -4\pi \delta_0(z)\), \(z \in \Omega(t)\), where \(\delta_0(z)\) is the Dirac distribution supported at the origin, where \(\phi\) is taken from the class of twice differentiable functions in \(\Omega(t) \setminus \{0\}\) with the asymptotics \(\phi \sim -\log |z|^2\) as \(z \to 0\).

**Proof.** Let us consider first the integral

\[
S_\varepsilon[\phi] = \int_{\Omega(t)} |\phi_z|^2 d\sigma_z = \int_{\Omega(t)} \chi_{\Omega(t)}|\phi_z|^2 d\sigma_z,
\]

where \(\chi_{\Omega(t)}\) is the characteristic function of \(\Omega(t)\). Then, due to Green’s theorem,

\[
\lim_{h \to 0} \frac{S_\varepsilon[\phi + hu] - S_\varepsilon[\phi]}{h} = 2 \int_{\Omega(t)} \chi_{\Omega(t)}|\phi_z|^2 d\sigma_z
\]

\[
= -\frac{1}{2} \int_{\Omega(t)} u \Delta \phi d\sigma_z + \frac{1}{2} \int_{\partial\Omega(t)} u \frac{\partial \phi}{\partial n} ds,
\]

in distributional sense for every \(C^\infty(\mathbb{C})\) test function \(u\) supported in \(\Omega(t)\). On the other hand, we have \(\partial \phi/\partial n \sim -2/\varepsilon\) as \(\varepsilon \to 0\) and \(u = 0\) on \(\partial\Omega(t)\). Therefore, the expression \(\mathcal{S}\) tends to

\[
-\frac{1}{2} \int_{\Omega(t)} u \Delta \phi d\sigma_z - 2\pi u(0),
\]
as \( \varepsilon \to 0 \), and the latter must vanish, that is equivalent to the Laplacian equation mentioned in the statement of the lemma. Obviously, the logarithmic term in the definition of \( S[\phi] \) does not contribute into the variation. □

Straightforward calculation gives

\[
\phi_z = -\frac{1}{f'} \left( \frac{f''}{f'} + \frac{1}{\zeta} \right) \circ f^{-1}(z, t)
\]

Hence, the action \( S \) can be expressed in terms of the parametric function \( f \) as

\[
(11) \quad S[f] = \lim_{\varepsilon \to 0} \left\{ \int_{U_\varepsilon} \left| \frac{f''}{f'} + \frac{1}{\zeta} \right|^2 \, d\sigma_\zeta + 2\pi \log \varepsilon \right\} + 2\pi \log |f'(0, t)|,
\]

or adding the logarithmic term into the integral we obtain

\[
(12) \quad S[f] = \int_{U} \left( \left| \frac{f''}{f'} + \frac{1}{\zeta} \right|^2 - \frac{1}{|\zeta|^2} \right) \, d\sigma_\zeta + 2\pi \log |f'(0, t)|.
\]

Within the quantum theory of Riemann surfaces the Liouville action is a Kähler potential of the Weil-Petersson metric on the space of deformations (Teichmüller space), see [28, 29]. We use a flat metric instead, nevertheless, as we show further on, there are several common features between smooth subordination evolution and the Liouville theory. In particular, we shall derive the variation of the logarithmic action \( S \) and give connections with the Virasoro algebra and the Kähler geometry on the infinite dimensional manifold \( \text{Diff} \, S^1/S^1 \).

4. Variation of the logarithmic action and the Kähler geometry on \( \text{Diff} \, S^1/S^1 \)

We denote the Lie group of \( C^\infty \) sense preserving diffeomorphisms of the unit circle \( S^1 = \partial U \) by \( \text{Diff} \, S^1 \). Each element of \( \text{Diff} \, S^1 \) is represented as \( z = e^{i\phi(\theta)} \) with a monotone increasing, \( C^\infty \) real-valued function \( \phi(\theta) \), such that \( \phi(\theta + 2\pi) = \phi(\theta) + 2\pi \). The Lie algebra for \( \text{Diff} \, S^1 \) is identified with the Lie algebra \( \text{Vect} \, S^1 \) of smooth (\( C^\infty \)) tangent vector fields to \( S^1 \) with the Poisson-Lie bracket given by

\[
[\nu_1, \nu_2] = \nu_1\nu_2' - \nu_2\nu_1'.
\]

There is no general theory of infinite dimensional Lie groups, example of which is under consideration. The interest to this particular case comes first of all from the string theory where the Virasoro (vertex) algebra appears as the central extension of \( \text{Vect} \, S^1 \) and gives the mode expansion for the energy-momentum tensor. The central extension of \( \text{Diff} \, S^1 \) is called the Virasoro-Bott group. Entire necessary background for the construction of the theory of unitary representations of \( \text{Diff} \, S^1 \) is found in the study of Kirillov’s homogeneous Kählerian manifold \( \mathcal{M} = \text{Diff} \, S^1/S^1 \). The group \( \text{Diff} \, S^1 \) acts as a group of translations on the manifold \( \mathcal{M} \) with the group \( S^1 \) as a stabilizer. The Kählerian geometry of \( \mathcal{M} \) has been described by Kirillov and Yuriev in [11]. The manifold \( \mathcal{M} \) admits several representations, in particular, in the space of smooth probability measures, symplectic realization in the space of quadratic differentials. Let \( A \) stand for the class of all analytic regular univalent functions \( f \) in \( U \) normalized by \( f(0) = 0, f'(0) = 1 \). We shall use its analytic representation of \( \mathcal{M} \) based on the class \( \tilde{A} \) of functions from \( A \) which being extended onto the closure \( \overline{U} \) of \( U \) are supposed to be smooth on \( S^1 \). The class \( \tilde{A} \) is dense in \( A \) in the local uniform topology of \( U \). There exists a canonical identification of \( \tilde{A} \) with
M. As a consequence, $\tilde{A}$ is a homogeneous space under the left action of $\text{Diff } S^1$, see [1] Theorem 1.4.1 and [9]–[12]. As it has been mentioned in Section 2, see also [20], a smooth subordination evolution is governed by the Löwner-Kufarev equation (4) with a function $p(\zeta, t)$ which may be Schwarz represented by its boundary values $\rho(e^{i\theta}, t)$, such that $4\pi \rho \in \text{Vect } S^1$.

**Theorem 1.** Let $z = f(\zeta, t)$ be the parametric function for the subordination evolution $\Omega(t)$, $t \in [0, \tau)$, $f(\zeta, t) = e^{i\zeta} + \ldots$. Let $S[f]$ stand for the logarithmic action. Then,

$$\frac{d}{dt} S[f] = \int_0^{2\pi} \left[ \text{Re} \left( 1 + \frac{e^{i\theta}f''}{f'} \right) \right]^2 \nu(e^{i\theta}, t) d\theta + \int_0^{2\pi} \text{Re} (e^{2i\theta}S_f) \nu(e^{i\theta}, t) d\theta - 2\pi,$$

where $\nu \in \text{Vect } S^1$, $\nu > 0$ and $\int_0^{2\pi} \nu(e^{i\theta}, t) d\theta = 4\pi$.

**Proof.** We start rewriting the expression for $S[f]$ as

$$S[f] = \int_U \left( \left| \frac{f''(\zeta, t)}{f'(\zeta, t)} \right|^2 + 2\text{Re} \frac{f''(\zeta, t)}{\zeta f'(\zeta, t)} \right) d\sigma_\zeta + 2\pi t,$$

and therefore,

$$\frac{d}{dt} S[f] = 2\text{Re} \int_U \left( \frac{f''(\zeta, t)}{f'(\zeta, t)} \right) \left( 1 + \frac{1}{\zeta} \right) \left( \frac{i}{f''} \frac{f''}{r} - \frac{f''}{f' r^2} \right) d\sigma_\zeta + 2\pi.$$

Now applying the Löwner-Kufarev representation $\dot{f} = \zeta f' p(\zeta, t)$, we get

$$\frac{d}{dt} S[f] = 2\text{Re} \int_U \left( \frac{f''(\zeta, t)}{f'(\zeta, t)} \right) \left( 1 + \frac{1}{\zeta} \right) \left( (1 + \zeta p) + \zeta p' \right) d\sigma_\zeta + 2\pi.$$

In order to apply Green’s theorem we remove the singularity at the origin by splitting the integral into two terms as

$$\frac{d}{dt} S[f] = 2\text{Re} \left( \int_U \cdots + \int_{|\zeta| < \varepsilon} \cdots \right) + 2\pi,$$

where the second term

$$\int_{|\zeta| < \varepsilon} \cdots = \int_0^{2\pi} \int_0^{\varepsilon} \left( \frac{\rho}{f'} + \frac{e^{i\theta}}{r} \right) (\text{holomorphic function}) r \, d\theta dr \to 0$$

as $\varepsilon \to 0$. Applying Green’s theorem for the first term and taking to account that $p(0, t) = 1$, we obtain

$$\int_U \cdots = \left( \frac{-1}{2i} \int_{S^1} \cdots d\zeta + \frac{1}{2i} \int_{|\zeta| = \varepsilon} \cdots d\zeta \right) \to \left( \frac{-1}{2i} \int_{S^1} \cdots d\zeta - \pi \right),$$

as $\varepsilon \to 0$. Thus, we have

$$\frac{d}{dt} S[f] = \text{Re} \int_0^{2\pi} \left( 1 + \frac{e^{i\theta}f''}{f'} \right) \left( (1 + e^{i\theta}p) + e^{i\theta}p' \right) d\theta,$$
Changing the order of integration implies
\[
\int_0^{2\pi} \text{Re} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Re} e^{i\theta} p'(e^{i\theta}, t) \, d\theta
+ \int_0^{2\pi} \text{Im} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Im} e^{i\theta} p'(e^{i\theta}, t) \, d\theta.
\]

These equalities are thought of as limiting values making use of the smoothness of \( f \) on the boundary. Let us denote by \( J_1, J_2 \) and \( J_3 \), the first, the second and the third term respectively in the latter expression. We have
\[
J_3 = \int_0^{2\pi} \text{Im} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Im} \int_0^{2\pi} \frac{2e^{i\theta} e^{i\alpha}}{(e^{i\alpha} - e^{i\theta})^2} \rho(e^{i\alpha}, t) \, d\alpha \, d\theta.
\]

Obviously,
\[
\frac{\partial}{\partial \alpha} \left( \frac{e^{i\alpha} + \zeta}{e^{i\alpha} - \zeta} \right) = \frac{-2 \zeta e^{i\alpha}}{(e^{i\alpha} - \zeta)^2}.
\]

Integrating by parts and applying the Cauchy-Schwarz formula we obtain
\[
J_3 = 2\pi \text{Re} \int_0^{2\pi} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Re} \int_0^{2\pi} \frac{2e^{i\theta} e^{i\alpha}}{(e^{i\alpha} - e^{i\theta})^2} \rho(e^{i\alpha}, t) \, d\alpha \, d\theta.
\]

Using the representation of the function \( \rho(\zeta, t) \) the integral \( J_2 \) admits the form
\[
J_2 = \int_0^{2\pi} \text{Re} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Re} \int_0^{2\pi} \frac{2e^{i\theta} e^{i\alpha}}{(e^{i\alpha} - e^{i\theta})^2} \rho(e^{i\alpha}, t) \, d\alpha \, d\theta.
\]

Changing the order of integration implies
\[
J_2 = \int_0^{2\pi} \text{Re} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Re} \int_0^{2\pi} \frac{2e^{i\theta} e^{i\alpha}}{(e^{i\alpha} - e^{i\theta})^2} \rho(e^{i\alpha}, t) \, d\alpha \, d\theta
\]
\[
= \int_0^{2\pi} \rho(e^{i\alpha}, t) \left( \int_0^{2\pi} \text{Re} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \frac{2e^{i\theta} e^{i\alpha}}{(e^{i\alpha} - e^{i\theta})^2} \right) \, d\alpha.
\]

Integrating by parts we obtain
\[
J_2 = \int_0^{2\pi} \rho(e^{i\alpha}, t) \left( -i \int_0^{2\pi} \frac{\partial}{\partial \theta} \text{Re} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \frac{e^{i\theta} + e^{i\alpha}}{e^{i\alpha} - e^{i\theta}} \, d\theta \right) \, d\alpha.
\]

The internal integral represents an analytic function by the Cauchy formula (modulo an imaginary constant). Taking into account the normalization at the origin we get
\[
J_2 = 2\pi \text{Re} \int_0^{2\pi} \left( e^{i\alpha} \frac{f''}{f'} + e^{2i\alpha} \left( \frac{f''}{f'} - \left( \frac{f''}{f'} \right)^2 \right) \right) \rho(e^{i\alpha}, t) \, d\alpha = J_3.
\]

Summing up \( J_1 + J_2 + J_3 \), and taking into account \( \nu = 4\pi \rho \), concludes the proof. \( \square \)

In the particular case of the Laplacian growth evolution this theorem has been proved in \( \cite{27} \). The normal velocity of the boundary is equal to the gradient of the Green function and \( \nu(e^{i\theta}, t) = 2 |f'(e^{i\theta}, t)|^2 \).

\[
\frac{d}{dt} S[f] = 2\pi \int_0^{2\pi} \left| 1 + e^{i\theta} \frac{f''}{f'} \right|^2 e^{i\theta} t \, d\theta
+ \int_0^{2\pi} \text{Re} \left( 1 + e^{i\theta} \frac{f''}{f'} \right) \text{Re} e^{i\theta} p'(e^{i\theta}, t) \, d\theta
\]
In two-dimensional conformal field theories [9], the algebra of energy momentum tensor is deformed by a central extension due to the conformal anomaly and becomes the Virasoro algebra. The Virasoro algebra is spanned by elements $e_k = \zeta^{1+k} \partial$, $k \in \mathbb{Z}$ and $c$ with $e_k + e_{-k}$, where $c$ is a real number, called the central charge, and the Lie brackets are defined by

$$[e_m, e_n]_{Vir} = (m-n)e_{m+n} + \frac{c}{12}m(m^2-1)\delta_{n,-m}, \quad [c, L_k] = 0.$$  

The Virasoro algebra ($Vir$) can be realized as a central extension of $Vect\ S^1$ by defining

$$[\phi \partial + ca, \psi \partial + cb]_{Vir} = (\phi' \psi' - \phi \psi')\partial + \frac{c}{12}\omega(\phi, \psi),$$

(wheras $[\phi, \psi] = \phi \psi' - \phi' \psi$), where the bilinear antisymmetric form $\omega(\phi, \psi)$ on $Vect\ S^1$ is given by

$$\omega(\phi, \psi) = -\frac{1}{4\pi} \int_0^{2\pi} (\phi' + \phi''')\psi d\theta,$$

and $a, b$ are numbers. This form defines the Gelfand-Fuks cocycle on $Vect\ S^1$ and satisfies the Jacobi identity. The factor of $1/12$ is merely a matter of convention.

The manifold $\mathcal{M}$ being considered as a realization $\hat{A}$ admits affine coordinates $\{c_2, c_3, \ldots\}$, where $c_k$ is the $k$-th coefficient of a univalent functions $f \in \hat{A}$. Due to de Branges’ theorem [9], $\mathcal{M}$ is a bounded open subset of $\{|c_k| < k + \varepsilon\}$.

The Goluzin-Schiffer variational formula lifts the actions from the Lie algebra $Vect\ S^1$ onto $\hat{A}$. Let $f \in \hat{A}$ and let $\nu(e^{i\theta})$ be a $C^\infty$ real-valued function in $\theta \in (0, 2\pi]$ from $Vect\ S^1$ making an infinitesimal action as $\theta \mapsto \theta + \tau \nu(e^{i\theta})$. Let us consider a variation of $f$ given by

$$L_\nu[f](\zeta) = -\frac{f''(\zeta)}{2\pi i} \int_{S^1} \frac{\nu(w)}{f(w) - f(\zeta)} \frac{dw}{w}.$$  

Kirillov and Yuriev [11, 12] have established that the variations $L_\nu[f](\zeta)$ are closed with respect to the commutator and the induced Lie algebra is the same as $Vect\ S^1$. Moreover, Kirillov’s result [9] states that there is the exponential map $Vect\ S^1 \to Diff\ S^1$ such that the subgroup $S^1$ coincides with the stabilizer of the map $f(\zeta) = \zeta$ from $\hat{A}$.

It is convenient [10] to extend $\mathcal{M}$ by complex linearity to $\mathbb{C}Vect\ S^1 \to Vect\ \hat{A}$. Taking $\nu_k = -i e^{ik\theta}$, $k \geq 0$ from the basis of $\mathbb{C}Vect\ S^1$, we obtain the expressions for $L_k = \delta_\nu f$, $f \in \hat{A} \simeq \mathcal{M}$ (see formula (13)), as

$$L_0 = \zeta f'(\zeta) - f(\zeta), \quad L_k = \zeta^{1+k} f'.$$

The computation of $L_k$ for $k < 0$ is more difficult because poles of the integrant. For example,

$$L_{-1} = f' - 1 - 2c_2 f, \quad L_{-2} = \frac{f'}{\zeta} - \frac{1}{f} - 3c_2 + (c_2^2 - 4c_3) f,$$

(see, e.g., [10]). In terms of the coordinates $\{c_2, c_3, \ldots\}$ on $\mathcal{M}$

$$L_k = \partial_k + \sum_{n=1}^{\infty} (n+1)c_n \partial_{k+n}, \quad L_0 = \sum_{n=1}^{\infty} nc_n \partial_n,$$

for $k > 0$, where $\partial_k = \partial/\partial c_{k+1}$.  

\[\{e_m, e_n\} = (m-n)e_{m+n} + \frac{c}{12}m(m^2-1)\delta_{n,-m}, \quad [c, L_k] = 0.\]
Neretin [16] introduced the sequence of polynomials $P_k$, in the coordinates \{c_2, c_3, \ldots\} on $\mathcal{M}$ by the following recurrent relations
\[
L_m(P_n) = (n + m)P_{n-m} + \frac{c}{12}m(m^2 - 1)\delta_{n,m}, \quad P_0 = P_1 = 0, \quad P_k(0) = 0,
\]
where the central charge $c$ is fixed. This gives, for example, $P_2 = \frac{c}{2}(c_3 - c_2^2)$, $P_3 = 2c(c_4 - 2c_2c_3 + c_2^2)$. In general, the polynomials $P_k$ are homogeneous with respect to rotations of the function $f$. It is worthy to mention that estimates of the absolute value of these polynomials has been a subject of investigations in the theory of univalent functions for a long time, e.g., for $|P_2|$ we have $|c_3 - c_2^2| \leq 1$ (Bieberbach 1916 [3]), for estimates of $|P_3|$ see [7, 14, 23, 24]. For the Neretin polynomials one can construct the generatrix function
\[
P(\zeta) = \sum_{k=1}^{\infty} P_k \zeta^k = \frac{e^{c_2^2/12}}{S_f(\zeta)},
\]
where $S_f(\zeta)$ is the Schwarzian derivative of $f$, Let $\nu \in \mathbb{C} \text{Vect } S^1$ and $\nu^g$ be the associated right-invariant tangent vector field defined at $g \in \text{Diff } S^1$. For the basis $\nu_k = -ie^{ik\theta}\partial$, one constructs the corresponding associated right-invariant basis $\nu^g_k$. By $\{\psi_{-k}\}$ we denote the dual basis of 1-forms such that the value of each form on the vector $\nu^g_k$ is given as
\[
(\psi_k, \nu^g_n) = \delta_{k+n,0}.
\]
Let us construct the 1-form $\Psi$ on $\text{Diff } S^1$ by
\[
\Psi = \sum_{k=1}^{\infty} (P_k \circ \pi) \psi_k,
\]
where $\pi$ means the natural projection $\text{Diff } S^1 \to \mathcal{M}$. This form appeared in [11, 22] in the context of the construction of a unitarizing probability measure for the Neretin representation of $\mathcal{M}$. It is invariant under the left action of $S^1$. If $f \in \tilde{A}$ represents $g$ and $\nu \in \text{Vect } S^1$, then the value of the form $\Psi$ on the vector $\nu$ is
\[
(\Psi, \nu)_f = \int_0^{2\pi} e^{2i\theta} \nu(e^{i\theta}) S_f d\theta,
\]
see [11, 22]. So the variation of the logarithmic action given in Theorem 1 becomes
\[
\frac{d}{dt} S[f] = \int_0^{2\pi} \left[ \Re \left( 1 + \frac{e^{i\theta} f''}{f'} \right) \right]^2 \nu(e^{i\theta}, t) d\theta + \Re (\Psi, \nu)_f - 2\pi.
\]
Taking into account the definition of the mean curvature $\kappa(z, t)$ of the boundary of $\Omega(t)$, and the normal velocity $\nu_n$, we conclude that
\[
\frac{d}{dt} S[f] = 4\pi \int_{\partial \Omega(t)} (\kappa \nu_n)^2 |dz| + \Re (\Psi, \nu)_f - 2\pi.
\]
