Isolation Period of $^{131}$I Administered Patients at NIMRA Jamshoro Pakistan

Abstract

Objectives: Since 1940s, the clinical use of unsealed radioisotopes has been in practice and after that the radioiodine’s oral administration became a gold standard for treating thyroid cancers. To protect the patients’ family members/caregivers and general public from unacceptably high radiation exposures, the therapeutic dosage of $^{131}$I administered patients are mandatory hospitalized in special isolation room until the exposure rate at one meter meets international and national limits. The current study was focused to measure the isolation duration of inpatients treated with radioiodine.

Material and Methods: The current study presents the duration of hospitalization of patients treated with $^{131}$I therapeutic dosages at Nuclear Institute of Medicine & Radiotherapy (NIMRA) Jamshoro, Pakistan from 2011 to 2013. Thirty Five patients (age range from 18 to 70 years) with cancer of thyroid administered with different activities (50 to 200 mCi (milliCurie)) of $^{131}$I admitted in special isolated room at different times were included in this study.

Results: The results indicated that only one (2.86%) of total patients discharged from hospital within first 24 hours of $^{131}$I administration whereas 17(48.57%), 11(31.43%) and 3(8.57%) patients were hospitalized in isolation room for 48, 72 and 96 hours after the administration of activity. Eleven percent of total isolated patients (n=4) stayed for 120 to 144 hours at the hospital.

Conclusion: The stay duration of $^{131}$I administered patients at NIMRA shows wide-ranging pattern. Due to rapid clearance of radioiodine form their bodies, more than half of patients stayed only 48 hours.

Keywords: Exposure; Hospitalization; Isolation room; Radioiodine; Stay duration

Introduction

After the radioiodine production by neutrons bombardment on stable iodine by Enrico Fermi in the Ernest O. Lawrence’s constructed cyclotron in 1930s [1], the first usage of radioiodine for treating hyperthyroidism was done by Saul Hertz and Arthur Roberts in 1940s [2] since then it became the milestone for treating thyroid cancer. $^{131}$I primarily emits 610 keV $\beta$ particle which initiate the emission of 364 keV $\gamma$ ray [3]. As $^{131}$I administered patients may likely be potential sources of adverse high radiation exposure to close family members/caregivers [4], so for protection of family members/caregivers and general public, the patients are discharged when the exposure rate level at one meter from the patients’ body falls to tolerable levels [5-7]. To regulate the discharge of hospitalized $^{131}$I administered patients, numerous standards and policies have been established [4]. The patients’ releasing criteria is set to ensure that no family member/caregiver or general public receives exposures above the regulatory dose limits [3,5,8-11] This study was initiated to discuss the isolation period of inpatients treated with radioiodine.

Material and Methods

The stay period of radioiodine administered patients solely depends upon the exposure rate measurement [4] by which the dose to others may be minimized [12,13]. If the administered radioiodine to the patient is more than 30 mCi, isolated hospitalization is necessary until the reduction of residual activity to 30 mCi or decline of the exposure rate to 50µSv/hr (micro Sievert) at one meter from patient [14,15]. Total 35, 71.43% (n=25) females and 28.57% (n=10) males treated with radioiodine at Nuclear Institute of Medicine and Radiotherapy (NIMRA) Jamshoro from 2011 to 2013 were included in the current study. The ages of patients were from 18 to 70 years and the administered activities of $^{131}$I were from 50 mCi to 200 mCi. Data of patients (age, sex, activity administered, date and time of $^{131}$I administration) were recorded [4,16]. Exposures rates at one meter from patients’ bodies on the first day (at the time of activity administration), then consecutive days until the patients’ hospital discharging day [3,9,17] were done with calibrated RM1001-RD LAMSE survey meter. Oral and written instructions about patients’ isolation at hospital and at home were given for minimization of dose to others [4,5,9,16,18-20]. The instructions were

a. During hospital stay, the patient will be alone in the isolated room;

b. Family members/ caregivers will be allowed for very short span of time for providing meals and water to the isolated patient;

c. Ensuring increased liquids intake;

d. Lemon/orange candies chewing to minimizing salivary glands dose;
e. Lactating mothers advised to complete cessation of breast milk to their babies to prevent radioiodine excreted to the babies;
f. Pregnancy avoidance for 4–6 months period after radioiodine administration;
g. Keeping maximum distance from family members/caregivers and general public, separate sleeping arrangements, avoiding of public transport travel and visiting public places (grocery stores, shopping centers, restaurants and theatres);
h. Instructing the patients and their caregivers to follow the instructions at home as maintained in isolation after discharge for one to two weeks for reduction of caregivers’/family members’ dose.

The patients’ releasing criteria from hospital’s isolation room was based on international and national regulatory agencies [4,5,10,11,16], that indicate that the patients may be discharged from hospital as exposure rate drops below 50µSv/hr at one meter [21] and this limit is PNRA’s regulatory requirements [5]; however, to avoid radiation dose to family members/caregivers, most patients were discharged from the hospital at exposure rate around 20–30µSv/hr.

Results

Amongst 35 patients who have administered $^{131}$I, 2.86% (n=1) stayed for just 24 hours in isolation room whereas 48.57% (n=17), 31.43% (n=11) and 8.57% (n=3) patients were stayed in isolation room at NIMRA for 48, 72 and 96 hours after the administration of radioiodine respectively. Remaining 4 patients (11.43%) stayed for 120 to 144 hours at the hospital as shown in Figure 1.

Continuous reduction in exposure rate shows the radioiodine excretion from the patients and we observed a mixed pattern of patients’ exposure rates. The exposure rate of radioiodine patients dropped to around initial exposure rate’s 50% within first 24 hours, and after each succeeding 24 hour period, the exposure rates dropped to 16.35%, 11.70% and 9.77% as expressed in Figure 2.

Overall, more than 80% fall in the initial exposure rate was recorded during patients’ stay at the hospital. From daily exposure rate measurements, the doses of caregivers during patients’ stay (providing meals and water to patients in a minute time span) were estimated from 0.0517 to 0.2125mSv (average 0.132mSv) and the majority of caregivers (more than 80%) received doses between 0.03mSv and 0.09mSv.

Discussion

The stay of patient in isolation room at the institute depends on many factors [4]
a. Activity administered,
b. Removal of activity from the patient,
c. Behavior of exposure rate.

The hospitalization of patient in isolation room for a 1-3 days or more till fall of the radioactivity in their bodies or the exposure rate at one meter to acceptable levels play major role to avoid unsuitable high radiation exposure to patients’ family members/caregivers [9,22]. The radioiodine uptake and exposure rate differs from patient to patient so their stay at hospital may differ also. The exposure rate, patients’ socioeconomic conditions and institution’s available resources must be considered as the majority of patients are financially poor and the institution has limited resources [4,23]. The studies [3,4,15,24-38] on % age excretion of $^{131}$I activity by researchers and, dose to caregivers/family members including current study are summarized in Table 1 & 2.

The studies conducted by Driver & Memon [3,4] and current study reveals that dearance of $^{131}$I from patients’ bodies is about 50% in first 24 hours where as 30% to 75% radioiodine excretion in first 24 hours observed by Tuntawiroon et al. & Parthasarathy et al. [25,26]. Tavakoli [27] reported that about 70% of activity cleared within first 24 hours. The study conducted by Markou P et al. [28] indicated that more than 60% of administered activity excreted within first 24 hours whereas 50-60% excretion administered activity was studied by Hamizah NMZ et al. [29] in the first 24 hours. Table 1 concludes that in all studies the excretion rate of $^{131}$I activity from patients is more than 75% within 72 hours of activity administration. Figure 1 shows the
Isolation Period of $^{131}$I Administered Patients at NIMRA Jamshoro Pakistan

%age excretion of $^{131}$I activity from isolated patients at NIMRA Jamshoro Pakistan.

Table 2 shows the radiation dose levels to family members/caregivers of radiiodine patient which pointed out that the doses to masses in various studies [4,30-38] including current report were in the magnitude of annual limit to general public (1mSv) which wrapping up that the patients treated with $^{131}$I do not share a significant radiation dose to the public [4,16,39]. Table 3 presents the data of patients’ stay at hospital including current study. Memon SA et al. [4] studied that stay duration of only 1.2% patients was 24 hours and 33.73%, 25.3% & 21.67% were discharged from hospital after 48, 72 & 96 hours. Al Haj [9] revealed that only 7% of the total patients were stayed just for 24 hours where as 76% and 14% of patients stayed for 48 and 72 hours. Culver et al. [21] reported that 26% of the treated patients were released after 24 hours from hospital whereas 67% and 7% were stayed for 48 and 72 hours respectively, Markou P et al. [28] studied that 75% of patients stayed for 48 hours and only 25% discharged from hospital within 72 hours. The study commenced by Lee JH et al. [40] reveals that 28% of patients discharged from hospital within 24 hours whereas stay of 60% patients in hospital was 48 hours. This study expressed that the patients’ stay at the hospital were in the magnitude of 2.86% for 24 hours whereas 48.57%, 31.43% and 8.57% of patients discharged after 48, 72 and 96 hours respectively. Figure 2 indicates the data of patients’ stay duration at NIMRA Jamshoro Pakistan.

Table 1: Summary of studies including current for % age of excretion of $^{131}$I activity from patients.

| Study                        | % Age of Excretion $^{131}$I Activity from Patients |
|------------------------------|----------------------------------------------------|
