ABSTRACT

We study the properties of the conformal blocks of the conformal field theories with Virasoro or W-extended symmetry. When the conformal blocks contain only second-order degenerate fields, the conformal blocks obey second order differential equations and they can be interpreted as ground-state wave functions of a trigonometric Calogero-Sutherland Hamiltonian with non-trivial braiding properties. A generalized duality property relates the two types of second order degenerate fields. By studying this duality we found that the excited states of the Calogero-Sutherland Hamiltonian are characterized by two partitions, or in the case of WA\(_{k-1}\) theories by \(k\) partitions. By extending the conformal field theories under consideration by a \(u(1)\) field, we find that we can put in correspondence the states in the Hilbert state of the extended CFT with the excited non-polynomial eigenstates of the Calogero-Sutherland Hamiltonian. When the action of the Calogero-Sutherland integrals of motion is translated on the Hilbert space, they become identical to the integrals of motion recently discovered by Alba, Fateev, Litvinov and Tarnopolsky in Liouville theory in the context of the AGT conjecture. Upon bosonisation, these integrals of motion can be expressed as a sum of two, or in general \(k\), bosonic Calogero-Sutherland Hamiltonian coupled by an interaction term with a triangular structure. For special values of the coupling constant, the conformal blocks can be expressed in terms of Jack polynomials with pairing properties, and they give electron wave functions for special Fractional Quantum Hall states.
1 Introduction

Since their introduction forty years ago [1] [2], the Calogero-Sutherland models, which describe one-dimensional particles interacting via pairwise inverse square potential, have gained considerable interest in theoretical and mathematical physics. The classical [3] and quantum [4, 5] Calogero-Sutherland systems have been proven to be completely integrable and the algebraic structures responsible for the solvability of these models have appeared in various area of theoretical physics, such as random matrix theories or two dimensional Yang-Mills theories. Moreover the Calogero-Sutherland systems have been shown to belong to a wide class of fully solvable systems associated to Lie algebras (see [6] [7]) which are relevant for the study of orthogonal polynomials associated to Lie root lattices.

Here we are interested into the connection between CS models and 2d conformal field theories (CFTs) which are based on Virasoro or, more generally, on WA$_{k-1}$ algebras. The latter are generated by $k-1$ conserved currents of spin $s=2,\ldots,k$ and their representations are associated to the root lattice $A_{k-1}$. The $k=2$ case corresponds to the Virasoro algebra. In the following, we will understand by Calogero-Sutherland model the quantum trigonometric version which describes particles on a ring. For this model, the exact evaluation of the ground state correlations, both static and dynamic, has been possible [8, 9] by using the theory of Jack polynomials.

As it was observed in [10, 11] by considering the properties of a class of multidimensional integrals, the Selberg-Aomoto integrals [12], the CS model is intrinsically related to the Virasoro algebra $Vir(g)$ with central charge $c = 1 - 6(g-1)^2/g$. Here, $g$ parametrizes the CS coupling, and the central charge $c$ is invariant under the change $g \rightarrow 1/g$ which corresponds to the duality transformation of the CS model [13] [14] [15]. One aspect of this connection is that the Jack polynomials characterize the Virasoro singular vectors [16] [17]. Analogous results hold for generic WA$_{k-1}$ algebras [18].

Another aspect of the relationship between $Vir(g)$ CFTs and CS($g$) model has been made explicit in the context of Schramm-Loewner evolutions (SLE) [19]. The probability measure associated to the evolutions of $N$ SLE traces is given by the conformal blocks involving $N$ second order degenerate fields, i.e. Virasoro primaries which possess a second level null vector in their Verma module. The conformal blocks involving these degenerate fields satisfy a second order differential equation which can be related to the CS Hamiltonian [19] [20]. Consequently, these conformal blocks form a new family of CS eigenfunctions. As we will discuss more in detail later, these eigenfunctions are in general not polynomial (they do not correspond to Jack polynomials) and are characterized by a non-abelian monodromy.

These findings were extended to the conformal blocks of $N$ primaries fields of a general WA$_{k-1}$ theory [21]. The main motivation in [21] was the study of a class of trial many-body wavefunctions for fractional quantum Hall effect (FQHE) at bosonic filling fraction $\nu = k/r$ [21] [22]. These states can be constructed from the conformal blocks of a series of minimal models of WA$_{k-1}$ algebras, the WA$_{k-1}(k+1,k+r)$ theories. This is the case for instance for the Moore-Read states [23] [24] with $k=2$, $r=2$ and for the Read-Rezayi states [24] with $k>2$, $r=2$ which play a paradigmatic role in the physics of non-abelian FQHE states. For a given WA$_{k-1}$ algebra, i.e. for a given central charge, there are two primary fields, which we indicate as $\Psi$ and $\sigma$ field [1] whose representation modules present the same degeneracy structure and whose correlation functions satisfy second order differential equations. In the CFT approach to FQHE, a quasihole wavefunction is given by a conformal block involving $\Psi$ and $\sigma$ fields. In [22] it was found that the differential operator which annihilates the quasihole wavefunction decomposes as the sum of two independent CS models acting separately on the coordinates of the $\Psi$ and of the $\sigma$ fields. These two CS Hamiltonians have dual coupling strength [22]. In this sense, the conformal block of $\Psi$ and $\sigma$ fields generalizes the duality kernel [13] [15] [14] in the non-abelian setting. By studying the edge excitations for non-abelian quantum Hall states, it has been shown in [23] [24] that this duality manifests also in the CFT characters characterizing the quasihole and particle sectors.

The purpose of this paper is to use the separation of variables mentioned above to study in more detail the new structures of the CS conformal block eigenfunctions. In this respect we are lead to consider the CFT which is based on the tensor product of the Heisenberg algebra and the WA$_{k-1}$ algebra, $u(1) \otimes$ WA$_{k-1}$. We will show that a conformal block of primary operators giving a CS eigenfunction plays the role of a reference ground state upon which we can define a family of CS excited eigenstates. These eigenstates are indexed by $k$ Young tableaux and are obtained by inserting into the conformal block a particular $u(1) \otimes$ WA$_{k-1}$ descendant.

---

1. We borrow the notations used in FQHE for, respectively, the electron and quasihole operator.
field. We will prove that the descendant states associated to the CS eigenfunctions form an orthogonal basis which, in the case of the $u(1) \otimes Vir(g)$ algebra, corresponds to the basis introduced in [28] to investigate the AGT conjecture [29], i.e. the expansion of the conformal blocks of Liouville theory (or more generally of CFTs based on Virasoro algebra [30, 31]) in terms of Nekrasov instanton functions [32] of $SU(2)$ gauge theories. In some sense, our finding is not surprising. The basis of descendant states have been shown [28] to diagonalize a series of commuting integrals of motion which, in the classical limit, correspond to the Benjamin-Ono conserved quantities. The advantage of our approach is that the connection between the CS Hamiltonian and the set of commuting integral of motion obtained in [28] is direct and explicit. For general $k$, the basis of descendant states associated to CS eigenfunctions is expected [28] to play an analogous role in the generalization of the AGT conjecture concerning the $SU(k)$ gauge theories and the $WA_{k-1}$ theories [33, 34].

Integrability of the CS Hamiltonian implies that there exists other, higher order conserved quantities which should be simultaneously diagonalized by the CS eigenfunctions. We have proven that the conformal blocks discussed above also obey a third-order differential equation which is related to the third order CS Hamiltonian. In order to prove this property, we have used the null vector condition for a particular descendant of the second order null vector. In our approach, it is still an open question how to systematically obtain the whole tower of integral of motion. We have verified that our third order integral of motion coincides with the expression $I_4$ conjectured in Appendix C of [28].

Our strategy is as follow: we first conjecture the eigenenergy formula for the CS non-polynomial eigenstates by using the separation of the variables between $\Psi$ and $\sigma$ fields and the singularity structure of the conformal blocks. Second, we translate the action of the CS Hamiltonian in the differential form into an operatorial form similar to that of [28], involving the Heisenberg and Virasoro (or more generally $WA_{k-1}$) generators. Then, using the bosonisation of Virasoro ($WA_{k-1}$) algebra, and performing a change of basis in the space of bosonic fields, like in [28] and in [33] we write the integral of motion associated to the CS Hamiltonian in terms of $k$ bosonic fields. As shown by Belavin and Belavin [36] in the case $k = 2$, for $g = 1$ the CS Hamiltonian splits into $k$ copies of one-component bosonized CS Hamiltonians [37], with a trivial coupling term involving the zero modes. This splitting explains in particular why we can characterize the generic CS eigenstates using $k$ partitions. Outside the point $g = 1$, the CS Hamiltonian is a sum of $k$ copies of one-component bosonized CS Hamiltonians with $g \neq 1$, plus a coupling term with a triangular structure in the creation/annihilation operators. The triangular structure of the coupling term insures that the spectrum is still given by the sum of $k$ one-component CS eigenenergies, each characterized by a partition. This proves our initial conjecture on the eigenenergies. Finally, the duality $g \rightarrow 1/g$ has a very simple realization in terms of the bosonized CS Hamiltonians and it gives rise to two dual bases in the Hilbert space.

The paper is organized as follows: sections 2 and 3 are reviewing basic facts about the CS model and CFT’s respectively and are fixing the notations. Since the generic formulas for the $WA_{k-1}$ algebras are rather complicated, we have preferred to treat first the Virasoro case, $k = 2$ in section 4 and then repeat the computation for generic $k$ in section 5. In Appendix A we specialize to the Ising case, which is a special case where a class of eigenfunctions become polynomial. Appendix B contains details on the derivation of the operatorial form of the CS integrals of motion and Appendix C is devoted to the Coulomb gas representation of the non-polynomial CS eigenfunctions.

2 Calogero-Sutherland model

In this section we review the standard relation between the Calogero-Sutherland model and Jack polynomials, and introduce some notations.

2.1 Integrability and Hamiltonians

The trigonometric version of Calogero-Sutherland model is a one-dimensional quantum model defined by the Hamiltonian:

$$ H_{CS}^{g} = -\frac{1}{2} \sum_{i=1}^{N} \frac{\partial^2}{\partial x_i^2} + g(g-1) \sum_{1 \leq i < j \leq N} \frac{(\pi/L)^2}{\sin^2[\pi(x_i - x_j)/L]} .$$

Our results can be related to those in [28] by changing $g \rightarrow -g$. 
The Hamiltonian (2.1) describes a system of $N$ particles at positions $x_i \in [0, L]$, $i = 1, \ldots, N$ on a circle of perimeter $L$ which interact with a long-range potential with coupling $g(g - 1)$. It proves convenient to introduce the variables

$$z_j = e^{2i\pi x_j / L},$$

(2.2)
in which the Hamiltonian (2.1) takes the form (up to a multiplicative factor)

$$H^g = \sum_{i=1}^{N} (z_i \partial_i)^2 - g(g - 1) \sum_{i \neq j} \frac{z_i z_j}{z_{ij}^2},$$

(2.3)

where $\partial_i = \partial / \partial z_i$ and $z_{ij} = z_i - z_j$. The total momentum operator reads as

$$\mathcal{P} = \sum_{i=1}^{N} z_i \partial_i.$$  

(2.4)

The Calogero-Sutherland model is completely integrable [39]. The total momentum $\mathcal{P}$ and the Hamiltonian $H^g$ belong to a set of $N$ functionally independent commuting operators $H^g_n$, whose first members are

$$H^g_1 = \mathcal{P} = \sum_{i=1}^{N} z_i \partial_i,$$

(2.5)

$$H^g_2 = H^g = \sum_{i=1}^{N} (z_i \partial_i)^2 - g(g - 1) \sum_{i \neq j} \frac{z_i z_j}{z_{ij}^2},$$

(2.6)

$$H^g_3 = \sum_{i=1}^{N} (z_i \partial_i)^3 + 3 \sum_{i \neq j} \frac{z_i z_j}{z_{ij}^2} (z_i \partial_i - z_j \partial_j).$$

(2.7)

These integral of motions, and the underlying integrability structure, can be derived using the so called Dunkl operator [6]. In order to compare the Hamiltonian (2.3) with expressions coming from CFT, it is particularly useful to conjugate with a generic Jastrow factor:

$$H^g \rightarrow H^{g, \gamma} = \Delta^{-\gamma} H^g \Delta^\gamma$$

$$\Delta^\gamma(z) = \prod_{i<j} (z_i - z_j)^\gamma.$$ 

(2.8)

Naturally, if a function $\Psi(z)$ is eigenvector of $H^g$, the function $\Delta^{-\gamma}(z)\Psi(z)$ is an eigenvector of $H^{g, \gamma}$ with the same eigenvalue. Under such a transformation the momentum $\mathcal{P}$ is simply shifted, and the Hamiltonian becomes

$$H^{g, \gamma} = \sum_{i=1}^{N} (z_i \partial_i)^2 + 2(\gamma - g)(g + \gamma - 1) \sum_{i < j} \frac{z_i z_j}{z_{ij}} + \gamma \sum_{i < j} \frac{z_i + z_j}{z_{ij}} (z_i \partial_i - z_j \partial_j)$$

(2.9)

up to a commuting term $a(g, \gamma) + b(g, \gamma) \mathcal{P}$, which is irrelevant for our purposes. When studying the connection between Calogero-Sutherland wavefunctions and CFT correlator we can safely consider the $z$ variables as general complex variables on the plane. Operators of the form (2.9) will be used later.

### 2.2 Calogero-Sutherland eigenfunctions : Jack polynomials and beyond

Whenever two coordinates $z_i$ and $z_j$ approaches each other, an eigenfunction $\Psi(z)$ of the Calogero-Sutherland Hamiltonian (2.3) has a regular singularity

$$\Psi(z) \sim (z_i - z_j)^\gamma$$

(2.10)

where the singular exponent $\gamma$ can only assume two possible values, namely $\gamma = g$ and $\gamma = 1 - g$. Imposing the behavior of the wavefunctions when two particles collide is equivalent to choosing a particular boundary conditions and thus fixing the Hilbert space in which the operator (2.1) acts. For instance in the case of a repulsive interaction ($g > 1$) between $N$ identical particles, it is natural to select wavefunctions behaving
as \((z_i - z_j)^g\) for every couple of particles (note that for \(g \geq 3/2\) this condition is a necessary one to ensure normalizability of the wavefunctions).

The usual wave-functions of this model are obtained by imposing the same boundary conditions for every couple of particles, and are of the form

\[
\Psi^+(z) = \Delta^g(z)F^+(z) \quad \quad \Psi^-(z) = \Delta^{1-g}(z)F^-(z)
\]

(2.11)

where \(F^\pm(z)\) are analytic functions when \(z_i \to z_j\) and \(\Delta^\gamma(z)\) is the Jastrow factor (2.8). It follows from (2.9) that these functions are eigenvectors of the so-called Laplace-Beltrami operator

\[
\mathcal{H}^\alpha = \sum_{i=1}^N (z_i \partial_i)^2 + \frac{1}{\alpha} \sum_{i<j}^{N} \frac{z_i + z_j}{z_{ij}} (z_i \partial_i - z_j \partial_j),
\]

(2.12)

for \(\alpha = 1/g\) and \(\alpha = 1/(1-g)\), respectively\footnote{In the following we are using mixed notations to denote the CS Hamiltonians and their eigenfunctions, using the index \(\alpha\) from the mathematical literature to denote the Laplace-Beltrami form of the CS Hamiltonian (2.12) and its eigenfunctions, including the Jack polynomials, while we use the index \(g\) for the untransformed Hamiltonians (2.14) and their eigenfunctions.}. The simplest eigenfunctions of this type are the symmetric polynomials known as Jack polynomials \(J^\alpha_\lambda\). They are labelled by partitions, \(i.e.\) a decreasing sequence of positive integers \(\lambda = [\lambda_1, \lambda_2 \ldots \lambda_N]\), and have eigenvalue

\[
E^\alpha_\lambda = \sum_{i}^{N} \lambda_i \left[ \lambda_i + \frac{1}{\alpha} (N + 1 - 2i) \right].
\]

(2.13)

For more details on Jack polynomials we refer the reader to \cite{15}. This method allows to construct two branches of eigenfunctions for the Calogero-Sutherland Hamiltonian (2.3)

\[
\Psi^+_\lambda(z) = \Delta^g(z)J^{1/g}_\lambda(z) \quad \quad \Psi^-_\lambda(z) = \Delta^{1-g}(z)J^{1/(1-g)}_\lambda(z)
\]

(2.14)

for which all pair of particles have the same boundary conditions as they approach each other. Such wavefunctions can be interpreted as describing particles with abelian fractional statistics in the sense of Haldane (2.10).

However, as it has been well discussed in \cite{20}, one can allow for more general boundary conditions, thus enlarging the Hilbert space under consideration. New eigenstates of (2.1) are shown to be given by certain CFT correlators, and we developed a method to tackle the problem of separating variables for these functions.

Moreover it is well known \cite{13,15,14} that there is a duality relating the Calogero-Sutherland models (2.1) with parameter \(g\) and \(1/g\). In particular this duality relates the corresponding Jack polynomials through the decomposition of \(\prod_{i,j} (1 + z_i w_j)\) separating the variables \(z_i\) and \(w_j\):

\[
\prod_{i,j} (1 + z_i w_j) = \sum_{\lambda} J^{1/g}_\lambda(z) J^g_\lambda(w),
\]

(2.15)

where \(\lambda'\) is the transpose of \(\lambda\). We studied how this duality manifests itself in this larger class of non-Abelian Calogero-Sutherland eigenfunctions described by certain CFT correlators, and we developed a method to tackle the problem of separating variables for these functions.

Before studying these non-Abelian eigenfunctions, we need to introduce some basic concepts of CFT which are behind this connection.
3 CFT: basic notions

We briefly review here the basic notions of CFTs. For a more in-depth introduction to CFT we refer the curious reader to [38].

The CFT is a two dimensional quantum field theory which enjoys conformal symmetry. The CFT approach aims to compute the correlator $\langle \Phi(z_1, \bar{z}_1), \ldots, \Phi(z_N, \bar{z}_N) \rangle$ of local fields $\Phi(z, \bar{z})$ by exploiting the infinite number of constraints which the conformal symmetry in two dimension imposes.

3.1 Virasoro algebra and primary fields

The conformal symmetry implies the existence of an holomorphic $T(z)$ and anti-holomorphic $\overline{T}(\bar{z})$ stress energy tensor. In two dimensions the conformal group is the tensor product of holomorphic and antiholomorphic Virasoro algebras which are formed respectively by the Virasoro operators $L_n$ and $\overline{L}_n$. For our purposes we consider only the holomorphic part of the theory, i.e. the holomorphic part of functions and fields.

The Virasoro operators $L_n$ are defined from the Laurent series of the stress-energy tensor

$$T(z)\Phi(w) \equiv \sum_n \frac{1}{(z-w)^{n+2}} L_n \Phi(w)$$

(3.1)

and obey the commutation relations

$$[L_n, L_m] = (n-m)L_{n+m} + \frac{c}{12} n(n^2-1)\delta_{n+m,0}.$$  

(3.2)

The above relations define the Virasoro algebra with central charge $c$.

A Virasoro primary field $\Phi_\Delta(z)$ satisfies the following relations

$$L_0 \Phi_\Delta = \Delta \Phi_\Delta \quad L_n \Phi_\Delta = 0 \text{ for } n > 0$$

(3.3)

The $\Delta$ appearing in the above expression is the conformal dimension of the field primary $\Phi$. To each primary field correspond an infinite family of fields, called descendants, which are obtained by acting with the Virasoro operators on $\Phi_\Delta$.

$$\Phi^{(n_1, n_2, \ldots, n_k)}_\Delta = L_{-n_k} \ldots L_{-n_1} \Phi_\Delta.$$  

(3.4)

The descendant fields $\Phi^{(n_1, n_2, \ldots, n_k)}_\Delta$ are eigenvectors of $L_0$ with eigenvalue $\Delta + L$, where $L = \sum n_i$ is called level and classify the descendant fields. For general values of $c$ and $\Delta$, all the independent fields are obtained by setting $n_1 \geq n_2 \geq n_3 \cdots \geq n_k$. The number of possible descendants at a level $L$ is then equal to the possible partitions of $L$.

3.2 Degenerate fields and differential equations

For special value of the conformal dimension $\Delta$, $\Delta = \Delta(c)$, one can establish the existence of a descendant field $\chi(\Delta, L)$ at a certain level $L$ such that $L_n \chi(\Delta, L) = 0$ for $n > 0$. The primary field $\Phi_\Delta$ is then said to be degenerate at level $L$ with $\chi(\Delta, L)$ being coined a null-vector.

It is convenient in this respect to parametrize the theory according to:

$$c = 1 - 6 \frac{(g-1)^2}{g}$$

(3.5)

and we denote the corresponding Virasoro algebra by $\text{Vir}(g)$. Trivially changing $g \to 1/g$ leaves the algebra invariant. As it will be clear later, the fact that we use the same notation $g$ for the parameter fixing the central charge in the above expression and the coupling of the Calogero-Sutherland model in (2.6) is not casual.

Degenerate primary fields $\Phi_{(r|s)}$ are labelled by two integers $r$ and $s$. Their conformal dimension is

$$\Delta_{(r|s)} = \frac{1}{4} \left( \frac{r^2-1}{g} + (s^2-1)g + 2(1-rs) \right),$$

(3.6)
and they have a null-vector at level \( L = rs \). Such a null vector is equivalent to a linear relation between usually independent descendants. The identity operator, for instance, can be identified with the field \( \Phi_{(1|1)} \) which presents a null-vector at level \( L = 1 \)

\[
L_{-1} \Phi_{(1|1)}(z) = \partial_z \Phi_{(1|1)}(z) = 0 .
\]

Of particular interest are the operators \( \Phi_{(1|2)} \) and \( \Phi_{(2|1)} \), with conformal dimension

\[
\Delta_{(1|2)} = \frac{3g - 2}{4} , \quad \Delta_{(2|1)} = \frac{3 - 2g}{4} .
\]

They are degenerate at level \( L = 2 \):

\[
(L_{-1}^2 - gL_{-2}) \Phi_{(1|2)} = 0 , \quad \left( L_{-1}^2 - \frac{1}{g} L_{-2} \right) \Phi_{(2|1)} = 0 .
\]

The null vector conditions characterizing a field \( \Phi_{(r|s)} \) yields a differential equation of order \( rs \) which is satisfied by any conformal block containing \( \Phi_{(r|s)} \). In particular, for the fields \( \Phi_{(1|2)} \) and \( \Phi_{(2|1)} \), this gives an order 2 differential equation which can be related to the Calogero-Sutherland Hamiltonian \[19, 20, 21, 22\].

Consider the most generic conformal block containing the field \( \Phi_{(1|2)} \), namely

\[
\langle \Phi_{(1|2)}(z_1) \Phi_{\Delta_2}(z_2) \ldots \Phi_{\Delta_N}(z_N) \rangle .
\]

Using standard contour deformation manipulations \[38\], the null-vector condition \((3.9)\) can be cast in the differential form

\[
\mathcal{O}^g(z) \langle \Phi_{(1|2)}(z_1) \Phi_{\Delta_1}(z_1) \ldots \Phi_{\Delta_N}(z_N) \rangle = 0
\]

where the order 2 differential operator \( \mathcal{O}^g(z) \) is

\[
\mathcal{O}^g(z) = \frac{\partial^2}{\partial z^2} - g \left( \sum_{j=1}^{N} \frac{\Delta_j}{(z - z_j)^2} + \frac{1}{z - z_j} \frac{\partial}{\partial z_j} \right).
\]

Likewise, conformal blocks containing the dual field \( \Phi_{(2|1)} \) obey a similar differential equation, which can be obtained by simply changing \( g \to 1/g \).

### 3.3 Heisenberg algebra \( H \)

The CFT based on the Heisenberg algebra \( H \) has an additional \( u(1) \) symmetry generated by a conserved current \( J(z) \) of conformal dimension one. As usual one defines the operator \( a_n \) through the Laurent series of the \( J(z) \) current:

\[
J(z) \equiv \sum_n \frac{1}{(z - w)^{n+1}} a_n \Phi(w)
\]

and they obey the so called Heisenberg algebra:

\[
[a_n, a_m] = n \delta_{n+m,0} .
\]

The stress energy tensor \( T(z) \) of the theory is given by:

\[
T(z) = \frac{1}{2} : J(z) J(z) :
\]

where \( : \) stands for the regularized product, and has central charge \( c = 1 \). The correspondent Virasoro operators \( l_n^{(1)} \) are written in terms of \( a_n \) as

\[
l_n = \frac{1}{2} \sum_{m \in \mathbb{Z}} a_{n-m} a_m \quad n \neq 0
\]

\[
l_0 = \sum_{m > 0} a_{-m} a_m + \frac{1}{2} a_0^2 .
\]

---

\(^4\)Throughout the paper we use the notation \( l_n \) to refer to the Virasoro operator associated to the \( u(1) \) CFT.
The \( t_n \) commute with the \( a_n \) in the following way

\[
[t_n, a_m] = -ma_{n+m}
\]

and form a Virasoro algebra with central charge \( c = 1 \)

\[
[t_n, t_m] = (n - m)t_{n+m} + \frac{1}{12}n(n^2 - 1)\delta_{n+m,0}.
\]

The simplest way to realize the \( c = 1 \) theory is by introducing a free boson \( \phi(z) \) normalized to

\[
\langle \phi(z)\phi(w) \rangle = -\ln(z-w).
\]

In terms of this boson the current \( J(z) \) reads

\[
J(z) = i\partial\phi(z).
\]

The primaries of the \([3.11]\) algebra are the vertex operators \( V_\beta =: e^{i\beta\phi(z)}: \)

\[
a_n V_\beta = 0, \quad n > 0
\]

\[
a_0 V_\beta = \beta V_\beta
\]

where \( \beta \) is the \( U(1) \) charge. From the \([3.17]\), it is easy to derive the conformal dimension \( \Delta_\beta \) of the vertex \( V_\beta: \)

\[
\Delta_\beta = \frac{\beta^2}{2}.
\]

From a vertex operator \( V_\beta \) all possible independent descendant can be obtained by applying the \( a_n \) operator, \( V_\beta^{(n_1, \ldots, n_k)} = a_{n_1} \cdots a_{n_k} V_\beta \) with \( n_1 \geq n_2 \cdots \geq n_k \). Note that, for the \( c = 1 \) theory, there are no singular vectors in this basis. Moreover the conformal block of \( N \) vertex operator are easily computed,

\[
\langle V_{\beta_1}(z_1) \cdots V_{\beta_k}(z_N) \rangle = \prod_{i<j} \delta_{ij} \beta_i \beta_j \quad \text{for} \quad \sum_i \beta_i = 0.
\]

## 4 Virasoro models: separation of variables and duality of partitions

In this section we introduce a set of Calogero-Sutherland eigenfunctions using conformal blocks in \( u(1) \otimes \text{WA}_{k-1}(g) \), and we study their properties. Since the generic formulas for the \( \text{WA}_{k-1} \) algebras are rather complicated, we start with the presentation of the Virasoro case \((k = 2)\) and postpone the treatment of the generic case to section 6.

### 4.1 Separation of variables

As explained in section 3, the fields \( \Phi_{(1|2)} \) and \( \Phi_{(2|1)} \) are of special importance, as any conformal block involving them obey a second order differential equation \([3.12]\). In order to build eigenfunctions of the Calogero-Sutherland Hamiltonian, we are led to consider functions of the form:

\[
\langle \Phi_{(2|1)}(w_1) \cdots \Phi_{(2|1)}(w_M) \Phi_{(1|2)}(z_1) \cdots \Phi_{(1|2)}(z_N) \rangle_{a,b}
\]

where the various conformal blocks are labelled by the double index \( a, b \). It is natural to use a double index because both the \( M \) fields \( \Phi_{(2|1)} \) and the \( N \) fields \( \Phi_{(1|2)} \) must fuse to the identity sector. There are \( 2^{N/2-1} \) such Bratelli diagrams for the fusions of \( \Phi_{(1|2)} \), and \( 2^{M/2-1} \) for \( \Phi_{(2|1)} \).

Upon multiplying by the correct \( u(1) \) factors, this function was shown in \([22]\) to obey a differential equation involving two CS Hamiltonians, and exhibits separation of variables in the sense of \([2.15]\). We introduce the function \( F_{M,N}^{a,b}(w; z) \)

\[
F_{M,N}^{a,b}(w; z) \equiv \langle \Phi_{(2|1)}(w_1) \cdots \Phi_{(2|1)}(w_M) \Phi_{(1|2)}(z_1) \cdots \Phi_{(1|2)}(z_N) \rangle_{a,b} = \prod_{1 \leq i < j} w_{ij}^{2h_{ij}} \prod_{i,j} (w_i - z_j)^{1/2} \prod_{1 \leq i < j} z_{ij}^{2h_{ij}},
\]
where we denote for simplicity
\[ h = \Delta_{(1|2)} = \frac{3g}{4} - \frac{1}{2}, \quad \bar{h} = \Delta_{(2|1)} = \frac{3}{4g} - \frac{1}{2}, \] (4.3)

The \( u(1) \) factors are such that the conformal block \( \mathcal{F}_{M,N}^{a,b}(w; z) \) is regular whenever two fields come close to each other, as long as they have the following fusion channels
\[
\Phi_{(1|2)}(z_i)\Phi_{(1|2)}(z_j) \sim \frac{1}{(z_i - z_j)^{2h}},
\]
(4.4)
\[
\Phi_{(2|1)}(w_i)\Phi_{(2|1)}(w_j) \sim \frac{1}{(w_i - w_j)^{2\bar{h}}},
\]
(4.5)
\[
\Phi_{(1|2)}(z_i)\Phi_{(2|1)}(w_j) \sim \frac{\Phi_2}{(z_i - w_j)^{1/2}}.
\]
(4.6)

In the generic case \( \Phi_{(1|2)} \times \Phi_{(1|2)} \rightarrow I \) is only one of the two possible fusion channels. However for \( g = (r+2)/3 \), the other fusion \( \Phi_{(1|2)} \times \Phi_{(1|2)} \rightarrow \Phi_{(1|3)} \) vanishes. These are the cases of interest for the construction of trial wavefunctions using Jack polynomials in the fractional quantum Hall effect [41, 42, 43, 44]. There the \( u(1) \) factor \( \prod_{i<j}(z_i - z_j)^{2h} \) is necessary to make the wave-function single valued in terms of the positions of the electrons \( z_i \) [23, 27].

As was shown in [22], the null-vector conditions (3.11) for \( \Phi_{(1|2)} \) and \( \Phi_{(2|1)} \) can be combined together to obtain the following differential equation
\[ \left[h^{\alpha}(z) + g \tilde{h}^{\tilde{\alpha}}(w)\right] \mathcal{F}_{M,N}^{a,b}(w; z) = 0 \] (4.7)

where \( h^{\alpha} \) belongs to the tower of commuting Calogero-Sutherland Hamiltonians
\[
h^{\alpha}(z) \equiv \mathcal{H}^{\alpha}(z) - \mathcal{E}_0^{\alpha} + \left(\frac{N - 2}{\alpha} - 1\right)[\mathcal{P}(z) - \mathcal{P}_0] - \frac{NM(M-2)}{4},
\]
(4.8)
\[
h^{\tilde{\alpha}}(w) \equiv \mathcal{H}^{\tilde{\alpha}}(w) - \mathcal{E}_0^{\tilde{\alpha}} + \left(\frac{M - 2}{\tilde{\alpha}} - 1\right)[\mathcal{P}(w) - \mathcal{P}_0] - \frac{NM(N-2)}{4},
\]
(4.9)

with \( \mathcal{P}(z) = \sum z_i \partial_i \) and \( \mathcal{H}^{\alpha} \) given by [2, 12] with coupling
\[
\alpha = \frac{1}{1-g}, \quad \tilde{\alpha} = \frac{1}{1-g^{-1}}, \quad \alpha + \tilde{\alpha} = 1.
\]
(4.10)

The constants \( \mathcal{E}_0^{\alpha} \equiv \mathcal{E}_{\lambda^0}^{\alpha} \) and \( \mathcal{P}_0 = \mathcal{P}_{\lambda^0} \) are given by
\[
\mathcal{E}_0^{\alpha} = \frac{h}{3}N(N-2)(N(2g-1) - 5g + 4), \quad \mathcal{P}_0 = N(N-2)h,
\]
(4.11)

while \( \mathcal{E}_0^{\tilde{\alpha}} \) and \( \mathcal{P}_0' \) are given by similar expressions with \( g \rightarrow g^{-1} \) and \( N \rightarrow M \) and \( \lambda^0 \rightarrow \lambda'^0 \). The degree of homogeneity of \( \mathcal{F}_{M,N}^{a,b}(w; z) \) in both the variables \( w \) and \( z \) is
\[
\mathcal{P}(z) + \mathcal{P}(w) = N(N-2)h + M(M-2)\tilde{h} + MN/2
\]
(4.12)
and it is clear that generically this function cannot be expanded in polynomial eigenbases neither in \( w \) nor in \( z \). However, it can be expanded on non-polynomial eigenfunctions of \( \mathcal{H}^{\alpha}(z) \) and \( \mathcal{H}^{\tilde{\alpha}}(w) \) and a duality property similar to that of section (A.4) holds
\[
\mathcal{F}_{M,N}^{a,b}(w; z) = \sum_{\lambda} \mathcal{F}_{\lambda'}^{\tilde{\alpha},\alpha}(w) \mathcal{F}_{\lambda}^{\alpha,b}(z).
\]
(4.13)

This looks like the duality property [13, 15, 13] of the Calogero-Sutherland model \( g \rightarrow 1/g \), with some differences. One difference consists in the boundary condition of the CS eigenfunctions, which force us to choose \( \alpha = 1/(1-g) \). The second is the non-abelian monodromy of the conformal blocks which implies the non-polynomial nature of the eigenfunctions.
4.2 Duality for the partitions

Although neither \( F^\alpha_b(z) \) nor \( F^\alpha,w(z) \) are polynomials, they are characterized by a “partition”\(^5\) such that the CS eigenvalues are of the form (2.13) for the couplings \( \alpha \) and \( \alpha' \) as in (2.9):

\[
\mathcal{E}_\lambda^a = \sum_{i=1}^{N} \lambda_i \left[ \lambda_i + \frac{1}{\alpha} \left( N + 1 - 2i \right) \right], \quad \mathcal{E}_{\lambda'}^a = \sum_{j=1}^{M} \lambda_j' \left[ \lambda_j' + \frac{1}{\alpha'} \left( M + 1 - 2j \right) \right].
\]

These “partitions” can be obtained by computing the behavior of \( F^\alpha_b(z) \) as \( z_1 \gg z_2 \gg \cdots \gg z_N \):

\[
\mathcal{F}_{0,N}^1(z) = \langle \Phi_{(1|2)}(z_1) \cdots \Phi_{(1|2)}(z_N) \rangle_1 \prod_{1 \leq i < j}^N \frac{z_{i,j}^{2h}}{z_{i,j}^2} \]

behaves in the limit \( z_1 \gg z_2 \gg \cdots \gg z_N \) as

\[
\frac{z_1^{2h(N-2)}}{z_2^{2h(N-2)}} \frac{z_3^{2h(N-4)}}{z_4^{2h(N-4)}} \cdots \frac{z_{N-1}^0}{z_N^0}
\]

and we encode this in a “partition” \( \lambda^0 \)

\[
\lambda_{2i-1}^0 = \lambda_{2i}^0 = 2h(N - 2i), \quad i = 1, \ldots, N/2.
\]

One can already check that this “partition”, when plugged in (2.13), is consistent with the CS eigenvalue \( \mathcal{E}_0^a \) and the degree \( \mathcal{P}_0 \) (4.11). Moreover in the polynomial case \( 2h \) is an integer and \( \lambda_0 \) becomes a true partition (with integer parts). This happens for \( g = (r + 2)/3 \); we recover the densest \( (k = 2, r) \) admissible partition \([45, 46]\) and the corresponding eigenfunction is a Jack polynomial. Similarly for \( \mathcal{F}_{M,0}^1(w) \), we infer that the “partition” corresponding to the lowest eigenstate in \( w \) is given by

\[
\lambda_{2j-1}^0 = \lambda_{2j}^0 = 2h(M - 2j), \quad j = 1, \ldots, M/2.
\]

and it corresponds under the duality to the maximum “partition”

\[
\Lambda_i^0 = \lambda_i^0 + \frac{M}{2}.
\]

We now turn to the description of the excited states \( \lambda \) appearing in the expansion (4.13). It is likely that they differ from the ground state \( \lambda^0 \) by \( \lambda_i - \lambda_i^0 = n_i \) with \( n_i \) positive integers, since they can be constructed from the ground state by applying some “creation operators” \([49]\) which increase degree of homogeneity by one. Moreover the relation (4.17) implies a relationship between the “partitions” which characterize the eigenfunctions of the two Hamiltonians \( \mathcal{H}^a(w) \) and \( \mathcal{H}^{a'}(z) \). We conjecture that the sets \( \lambda \) and \( \lambda' \) are characterized by two sets of dual partitions \( n_i^{c,o} \) and \( n_i^{e,o} \) in the following manner (see Fig. 1)

\[
\lambda_{2i-1} = \Lambda^0_{2i-1} - n_{2i-2+i+1}^{c,o}, \quad \lambda_{2i} = \Lambda^0_{2i} - n_{2i-2+i+1}^{c,o},
\]

\[
\lambda_{2j-1} = \Lambda^0_{2j-1} + n_j^{e,o}, \quad \lambda_{2j} = \Lambda^0_{2j} + n_j^{e,o},
\]

with \( n_i^{c,o} \leq M/2 \) and \( n_i^{e,o} \leq N/2 \).

For a partition \( n \) with lines of length \( n_i \) the dual partition \( n' \), with lines of length \( n_j' \), is the partition where

\( ^5 \)We use the quotes in “partition” to stress that the parts \( \lambda_i \) are generally not integers, which is related to the fact that the corresponding eigenfunctions are not polynomials. The dual “partition” \( \lambda' \) is not the transpose of the “partition” \( \lambda' \); they are related as specified by the equations (4.21) and (4.22), see also Figure 1
Figure 1: The relation between the sets of numbers $\lambda$ and $\lambda'$ is realized using two sets of dual Young diagrams, $n^o$, $n'^o$ and $n^e$, $n'^e$. The blocks in pink correspond to $\lambda^0$ and $\lambda'^0$, while the maximum envelopes, in red, correspond to $\Lambda^0 \equiv M/2 + \lambda^0$ and $\Lambda'^0 \equiv N/2 + \lambda'^0$. The maximum value of the partitions $n^o$ and $n^e$ is $(M/2)^N/2$.

the lines of $n$ become the columns of $n'$. For two partitions $n$ and $n'$ dual to each other the following relations hold [13]

$$b(n) \equiv 2 \sum_i (i-1)n_i = \sum_j n'_j(n'_j - 1) , \quad |n| \equiv \sum_i n_i = |n'| . \quad (4.24)$$

We can check this conjecture by evaluating the eigenvalues of $\mathcal{H}_z^\alpha$ and $\tilde{\mathcal{H}}^\tilde{\alpha}(w)$ on the corresponding states, eigenvalues which are given in equation (2.13)

$$E_\alpha^{\lambda} = \sum_{i=1}^N \lambda_i |1 - g)(N + 1 - 2i) , \quad E_{\tilde{\alpha}}^{\lambda'} = \sum_{j=1}^M \lambda'_j |1 - g^{-1})(M + 1 - 2j) . \quad (4.25)$$

Substituting the expressions (4.21), (4.22) in the above formulas and using the notations from equation (4.24) we obtain now the expressions of the energies of the intermediate states purely in terms of the partitions $n^{e,o}$ and $n'^{e,o}$ as

$$\mathcal{E}_\lambda^o = [b(n^{e,o}) + b(n^{e,o})] - g [b(n^o) + b(n^e)] + (1 - g)N - M + g(|n^{e,o}| + |n^{e,o}|) + 2(g - 1)|n^{e,o}| + E_\lambda^o \quad (4.26)$$

and

$$\mathcal{E}_{\lambda'}^{\tilde{\alpha}} = [b(n^{e,o}) + b(n^{e,o})] - \frac{1}{g} [b(n^{e,o}) + b(n^{e,o})] + \frac{2g - 3}{g} (|n^{e,o}| + |n^{e,o}|) + \frac{2(g - 1)}{g} |n^{e,o}| + E_{\lambda'}^{\tilde{\alpha}} . \quad (4.27)$$
It is a non-trivial check of the conjectured expressions (4.21), (4.22) that the two eigenvalues $E^\alpha_n$ and $E^\tilde{\alpha}_n$ satisfy the duality condition implied by (4.7)

$$E^\alpha_n - E^\alpha_0 + g(E^\tilde{\alpha}_n - E^\tilde{\alpha}_0) + \frac{(N - 2)}{\alpha} (P_\lambda - P_0) + g \left( \frac{M - 2}{\tilde{\alpha}} - 1 \right) (P_{\lambda'} - P_{\tilde{\alpha}'}) =$$

$$E^\tilde{\alpha}_{n'} - E^\tilde{\alpha}_0 + \frac{NM}{2} \left( \frac{N - 2}{\alpha} - 1 \right) = \frac{NM(M - 2)}{4} + gMN(N - 2) \frac{4}{4}.$$  (4.28)

Although the manipulations from this section may seem too abstract, due in particular to the fact that the properties of the non-polynomial eigenfunctions of the Calogero-Sutherland model are largely unexplored, one can stick to the particular case $g = 4/3$, which corresponds to the Ising CFT. In this case, the dimension of the fermion is 1/2, so that $2h = 1$ and the “partition” $\lambda_0$ becomes a true partition, and the associate eigenfunctions indexed by $\lambda$ are Jack polynomials with clustering properties. This case is well under control, and we treat this particular case in the Appendix A.4. As an example, we give the explicit expressions of non-polynomial eigenfunctions of the Calogero-Sutherland model are largely unexplored, one can stick to the particular case $g = 4/3$, which corresponds to the Ising CFT. In this case, the dimension of the fermion is 1/2, so that $2h = 1$ and the “partition” $\lambda_0$ becomes a true partition, and the associate eigenfunctions indexed by $\lambda$ are Jack polynomials with clustering properties. This case is well under control, and we treat this particular case in the Appendix A.4. As an example, we give the explicit expressions of the non-polynomial eigenfunctions $\mathcal{F}_M^{a,1}(w)$ for $M = 4$ and $N = 2$. In the Ising case, due to the constraint of $(2, 2, N)$ admissibility of the partition $\lambda$, (A.18), $n^o$ and $n^e$ obey the extra mutual constraints

$$0 \leq n^o_i = n^e_i \leq M/2, \quad n^o_{i+1} \leq n^e_i + 2.$$  (4.29)

It is interesting to know whether in general there are any constraints for the partitions $n^e$ and $n^o$ in addition to the ones in equation (4.23).

Let us comment on the significance of the expressions (4.21) and (4.22). Remembering that the energy for a polynomial eigenfunction of the Calogero-Sutherland model with $N$-particles indexed by the partition $n$ can be written as

$$E^\alpha_n = \sum_{i=1}^{N} n_i \left[ \frac{1}{\alpha} (N + 1 - 2i) \right] = b(n') - \frac{1}{\alpha} b(n) + \left( \frac{N - 1}{\alpha} + 1 \right) |n|.$$  (4.30)

the expression (4.21) suggests that the intermediate states $\lambda$ are described by two Calogero-Sutherland models, each with $N/2$ particles, with eigenfunction indexed by the two partitions $n^e$ and $n^o$ and at coupling constant $\alpha = 1/g$. States which are indexed by a pair of Young diagrams appeared in the expression of the Nekrasov’s instanton partition function [32] which can be related to the conformal blocks of the Liouville theory [28]. Since Liouville theory can be treated exactly in the same fashion as the generic Virasoro models in this section, provided that we change the sign of the coupling constant $g$, one can suspect that the basis we have identified in this section is related to the basis used to prove the AGT conjecture [29, 28]. In the next section we are going to show that this basis indeed corresponds to the basis considered by Alba, Fateev, Litvinov and Tanopolsky in [28].

5 Hidden integrable structure in $u(1) \otimes$ Virasoro modules

5.1 The $u(1)$ sector and the Coulomb gas representation of the minimal model

An essential feature in proving the duality (4.7) is the presence of the term $\prod_{i,j} (z_i - w_j)^{1/2}$ which dresses the conformal block in $\mathcal{F}_{M,N}^{a,b}(w; z)$. This factor can be accounted for by introducing an $u(1)$ component in the CFT. In the context of the quantum Hall effect, the $u(1)$ component carries the electric charge. The corresponding conserved current is $J(z) = i\partial\phi(z)$. The $u(1)$ factors introduced in the previous section where inherited from the fractional quantum Hall effect, and it turns out to be more convenient to work with a slightly modified function

$$\mathcal{F}_{M,N}^{a,b}(w; z) \equiv \mathcal{F}_{M,N}^{a,b}(w; z) \prod_{1 \leq i < j}^{N} z_i^{1-g} \prod_{1 \leq i < j}^{M} w_i^{1-g^{-1}}.$$  (5.31)

This slight modification does not spoil the separation of variables since it does not mix the variables $z$ and $w$. However it changes the Laplace-Beltrami operators $\mathcal{H}^a$ and $\mathcal{H}^\tilde{a}$ involved in the differential equation (4.7), (4.9) to the proper Calogero-Sutherland Hamiltonian $H_2^a$ and $H_2^{1/g}$, respectively.
The theory. Let us consider the first possibility for the field identification in (5.35); we can then write for the
The identification of the vertex operators with reflected charge
\( \alpha \)
is to interpret the decomposition
\[ \text{Vir} \text{Calogero-Sutherland Hamiltonians and integrals of motions acting in the modules of} \]
The separation of variables (4.7) and (4.13) can be seen as a corollary of a deeper connection between
\( 5.2 \) The Hilbert space and the Calogero-Sutherland integrals of motion
\( \text{Vir} \)\( \text{Commuting bosonic fields.} \)
is tempting to relate the decoupling relation (4.7) to the fact that the two vertex operators are built from
bosonic modes \( L \)
Let us note that the Virasoro modes \( L \), which in turn is equivalent to \( g \rightarrow 1/g \). This operation exchanges the operators \( V(z) \) and \( V(z) \) in equation (5.36) and corresponds to the duality transformation. It is tempting to relate the decoupling relation (4.7) to the fact that the two vertex operators are built from commuting bosonic fields.

5.2 The Hilbert space and the Calogero-Sutherland integrals of motion
The separation of variables (4.7) and (4.13) can be seen as a corollary of a deeper connection between
Calogero-Sutherland Hamiltonians and integrals of motions acting in the modules of \( \text{Vir}(g) \otimes \mathcal{H} \). The idea is to interpret the decomposition

\[ \langle \tilde{V}(w_1) \ldots \tilde{V}(w_M) V(z_1) \ldots V(z_N) \rangle_{a,b} = \sum_{\lambda} F_{\lambda}^{1/g,a}(w) F_{\lambda}^{g,b}(z) \]
as coming from the insertion of a complete basis of descendants between the operators \( \tilde{V}(w) \) and \( V(z) \), with a very particular basis ensuring that each function \( F_{\lambda}^{g,b}(z) \) is an eigenvector of the CS Hamiltonians \( H_g^\lambda \).
Such a basis is in fact unique, and one of the main result of this paper is the construction of such a basis. In this section we present this result, while more details about its derivation can be found in Appendix B.
We focus on the fields \( \tilde{V} \) from (5.33), the results for \( \tilde{V} \) being simply obtained by substituting \( g \rightarrow 1/g \). We are therefore concerned with correlation functions of the form

\[ f_\mu^+(z_1, z_2, \ldots, z_N) = \langle \mu | V(z_1) V(z_2) \ldots V(z_N) | P \rangle \]
\[ f_\mu^-(z_1, z_2, \ldots, z_N) = \langle P | V(z_1) V(z_2) \ldots V(z_N) | \mu \rangle \]
where \( |\mu \rangle \) is an arbitrary field (primary or descendant), and \( |P \rangle \) is a primary field (i.e. annihilated by \( a_m \) and \( L_m \) for \( m > 0 \)) and we dropped the conformal block label as it does not play a role in this analysis. The order \( n \) CS Hamiltonian \( H_n^g \) acting on the variables \( (z_1, \ldots, z_N) \) can be rewritten as an operator \( I_{r+1}^g \) acting on the state \( \tau_0^\pm \)

\[ H_n^g f_{\mu}^+(z_1, z_2, \ldots, z_N) = \sum_{\nu} \left[ I_{r+1}^g \right]_{\mu, \nu} f_{\nu}^+(z_1, z_2, \ldots, z_N) \]

\( ^6 \)The basis \( I_{r+1}^\pm(g) \) we will use in the following corresponds in fact to a combination of \( H_s^g \) with \( s \leq r \), see e.g. (B.34).
To put it differently, \( f_\lambda^\pm (z_1, \ldots, z_N) \) is an eigenstate of \( H_r(g) \) iff \( |\mu\rangle \) is an eigenstate of \( I_r^{(\pm)}(g) \). We checked this correspondence and computed the value of \( H_{r+1}(g) \) for \( r = 2, 3 \) in Appendix B.

This expression for \( H_2(g) \) comes from the degeneracy at level 2 in the module of the operator \( V \):

\[
(L_{-1}^2 - gL_{-2}) V = 0
\]

By standard contour deformation (see Appendix B for more details), this relation yields a differential equation of order 2 for any correlator involving \( V(z) \). For a symmetric correlation function of the form (5.39), this differential equation becomes the order 2 CS Hamiltonian

\[
H_2^g = \sum_{i=1}^{N} \left( z_i \frac{\partial}{\partial z_i} \right)^2 + g(1 - g) \sum_{i \neq j} \frac{z_i z_j}{z_{ij}^2}
\]

up to an extra term corresponding to the contours being at infinity, yielding an operator acting on \( |\mu\rangle \). This is of course the operator \( I_3^+(g) \). The operator which acts on \( |\mu\rangle \) is \( I_3^-(g) \) with

\[
I_3^{(\pm)}(g) = 2(1 - g) \sum_{m \geq 1} ma_{-m}a_m \pm \sqrt{2g} \sum_{m \neq 0} a_{-m}L_m \pm \sqrt{g} \left( \sum_{m, k \geq 1} a_{-m-k}a_{m+k} + a_{-m}a_{-k}a_{m+k} \right)
\]

The relation for \( H_3^g \) can be obtained from the degeneracy at level 3

\[
(L_{-1} + 3\sqrt{g}/2a_{-1}) (L_{-1}^2 - gL_{-2}) V = 0
\]

and the explicit expression for \( I_4^\pm(g) \) is given in (5.38). \( I_4(g) \) coincides, up to the change \( g \rightarrow -g \) and a change in normalizations of the bosonic operator, with the operator \( I_4(g) \) which appeared in [28] in the context of the AGT conjecture. We conjecture that this structure holds true for any \( r \), in the sense that the higher integrals of motion would correspond to a particular descendent of the second order degenerate vector

\[
\sum_{n_1 + \ldots + n_l = r-2} c_{n_1, \ldots, n_l} L_{-n_l} L_{-n_1} \cdots a_{-n_1} a_{-n_l} (L_{-1}^2 - gL_{-2}) V = 0
\]

with coefficients \( c_{n_1, \ldots, n_l} \) to be determined. This would define two towers of commuting integral of motions \( I_r^+(g) \) and \( I_r^-(g) \), charge conjugate from one another.

In the module of the primary field \( P \), i.e. the set of all \( Vir(g) \otimes \mathcal{H} \) descendants of \( P \), one can diagonalize the operators \( I_r^{(\pm)}(g) \). We denote the corresponding basis of descendants \( |P_\lambda^\pm(g)\rangle \). These two orthogonal bases are charge conjugate from one another. In this basis, the OPE of \( N \) vertex operators \( V(z_1) \cdots V(z_N) |P \rangle \) enjoys a natural action of Calogero-Sutherland Hamiltonians. All the \( N \)-point functions

\[
F_{\lambda}^{(g, \pm)}(z_1, \ldots, z_N) = \langle P_\lambda^+(g) | V(z_1) \cdots V(z_N) | P \rangle
\]

are simultaneously eigenstates of the whole tower of Hamiltonians \( H_0^g \) because of the correspondence (5.40).

As the CFT remains unchanged under \( g \rightarrow 1/g \), one could think of introducing another two bases, namely \( |P_\lambda^\pm(1/g)\rangle \). However the operators \( I_r^{(\pm)}(g) \) are self dual in the sense:

\[
I_r^{(\pm)}(g) \propto I_r^{(\mp)}(1/g)
\]

and these bases are related through

\[
|P_\lambda^\pm(g)\rangle = |P_\lambda^+(1/g)\rangle
\]
This relation induces the duality (4.7), as the (5.40) implies the following structure for the $M$ points OPE of $\tilde{V}$:

$$\tilde{V}(w_1) \cdots \tilde{V}(w_M)|P\rangle = \sum_\lambda F^{(1/g,\cdot)}(w_1, \cdots, w_M)|P(1/g)\rangle$$

(5.52)

where $F^{(1/g,\cdot)}(z_1, \cdots, z_N)$ diagonalize all CS Hamiltonians $H^1_{\lambda}/g$.

Upon inserting a complete basis of descendants $|P(1/g)\rangle = |P^+(1/g)\rangle$ between the $V$'s and $\tilde{V}$'s in the mixed correlator, we obtain a generic separation of variables

$$\langle P|V(z_1)V(z_2)\cdots V(z_N)\tilde{V}(w_1)\cdots \tilde{V}(w_M)|P\rangle = \sum_\lambda F^{(g,-)}(z_1, \cdots, z_N)F^{(1/g,\cdot)}(w_1, \cdots, w_M)$$

(5.53)

and we recover (5.37) when we choose the primary $P$ to be the identity.

### 5.3 The Virasoro model at $g = 1$

As noticed by Belavin and Belavin for the Liouville case [36], at $g = 1$ the structure of the Hilbert space of the conformal field theory and the duality become particularly transparent, in particular we can better understand the role of the extra $u(1)$ component. After a change of basis, the theory can be described with two copies of independent bosons, coupled only by zero modes. We give the details of the construction below and we use the definitions from the section 5 for the bosonisation of the minimal model. Let us note that at $g = 1$ the charge at infinity $c_0$ defined in (5.34) vanishes and the stress-energy tensor is purely quadratic in the bosonic field.

The first non-trivial integral of motion, $I_3^\pm$ is in this case cubic in the bosonic fields,

$$I_3^\pm (1) = \pm \left[ \sqrt{2} \sum_{m \neq 0} a_m L_m + \frac{1}{\sqrt{2}} \sum_{m,k > 0} (a_{-m-k}a_m a_k + a_{-m}a_k a_{m+k}) \right].$$

(5.54)

Moreover, it is the odd in the operators $a_m$, so that

$$a_m \rightarrow -a_m \quad \text{sends} \quad I_3^+ (1) \rightarrow I_3^- (1) = -I_3^+ (1)$$

(5.55)

and it is even in the operators $b_m$, since $L_m$ is quadratic in the $b_m$'s. The next integral of motion, $I_4^\pm$ is even in both sets of bosonic creation/annihilation operators $a_m$ and $b_m$,

$$I_4^+ (1) = -\sum_{m > 0} L_m L_m - \frac{3}{4} \sum_{m,p > 0} (2L_p a_m a_p + 2a_m a_p L_p + a_m a_p L_p a_m)$$

$$- \frac{1}{2} L_0^2 - 3L_0 \sum_{m > 0} a_m a_m - \frac{1}{8} \sum_{m_1 + m_2 + m_3 + m_4 = 0} a_{m_1} a_{m_2} a_{m_3} a_{m_4} \quad : a_{m_1} a_{m_2} a_{m_3} a_{m_4} : - \frac{1}{2} \sum_{m \geq 1} m^2 a_m a_m$$

(5.56)

We are going to show that these two integrals of motion can be separated each into sums of two integrals of motion for independent bosons, plus a part containing the zero mode $b_0$. Let us rotate the bosonic basis and define the new bosonic operators

$$c_m = \frac{1}{\sqrt{2}} (a_m + b_m), \quad \bar{c}_m = \frac{1}{\sqrt{2}} (a_m - b_m)$$

(5.57)

and define the mutually commuting Hamiltonians $\mathcal{I}_2(c)$, $\mathcal{I}_3(c)$ and $\mathcal{I}_4(c)$ as

$$\mathcal{I}_2(c) = \sum_{m > 0} c_m c_m$$

(5.58)

$$\mathcal{I}_3(c) = \sum_{m,k > 0} (c_{-m-k} c_m c_k + c_{-m} c_{-k} c_{m+k})$$

(5.59)
The Hamiltonian \((5.59)\) is known to be the one-component Calogero-Sutherland Hamiltonian at \(g = 1\) expressed in collective variables \([37, 11]\) while \((5.60)\) is the next corresponding conserved charge. It is likely that there exists a whole tower of conserved charges \(I_i(c)\), each being of total degree \(r\) in the bosonic operators. Their joint eigenfunctions are given by the Schur polynomials,

\[ |n\rangle = S_n(c)|0\rangle . \]  

The eigenstates are indexed by partitions \(n\) and the corresponding eigenvalues are given by the simple formulas

\[ e_{2,n} = \sum_i n_i = |n| , \]  

\[ e_{3,n} = \sum_i n_i(n_i - 2i + 1) = b(n') - b(n) , \]  

\[ e_{4,n} = -\sum_i \left[ (n_i - i + \frac{1}{2})^3 + (i - \frac{1}{2})^3 \right] - \frac{1}{4} \sum_i n_i . \]  

where \(b(n)\) is defined in equation \((4.24)\). On the expression \((5.63)\) it is obvious that dual partitions \(n\) and \(n'\) have opposite energies \(e_{3,n} = -e_{3,n'}\). It is slightly more complicated to show that \(e_{4,n} = e_{4,n'}\). On the Schur polynomials, the duality acts like \(S_n(-c) \sim S_{n'}(c)\) where \(n'\) is the partition dual to \(n\). These findings are consistent with the fact that changing the sign of the bosonic operators \(c_k\) changes the sign of the Hamiltonian \(I_3(c)\) and it leaves \(I_4(c)\) invariant.

The Hamiltonian \(I_3(1)\) can be written as a sum of two commuting Hamiltonians depending on the bosonic modes \(c_m\) and \(\bar{c}_m\)

\[ I_3^+(1) = \frac{1}{\sqrt{2}} \sum_{m,k>0} (a_{m-k}a_ka_k + a_{-m}a_{-k}a_{m+k}) + \frac{1}{\sqrt{2}} \sum_{m,0,k \in \mathbb{Z}} a_{-m}b_{m-k}b_k \]  

\[ = I_3(c) + I_3(\bar{c}) + \sqrt{2}b_0(I_2(c) - I_2(\bar{c})) , \]  

the two copies being only related by the zero mode \(b_0\). On the module of the identity, the last term in the previous expression vanishes. A similar property is valid for the next conserved charge,

\[ I_4^+(1) = I_4(c) + I_4(\bar{c}) - 3\sqrt{2}b_0[I_3(c) - I_3(\bar{c})] - \frac{3b_0^2}{2}[I_2(c) + I_2(\bar{c})] - \frac{b_0^4}{8} . \]  

The immediate consequence of the separation \((5.65), (5.66)\) is that the eigenfunctions are factorized, for example for the module of the identity

\[ |n^o, n^e\rangle = [S_{n^o}(c)S_{n^e}(\bar{c}) + S_{n^o}(\bar{c})S_{n^e}(c)] |0\rangle \]  

where \(S_n(c)\) is the Schur polynomial associated to the partition \(n\) constructed from the creation operators \(c_{-k}\). We have isolated the combination which is symmetric in \(b_k \rightarrow -b_k\), since this is what we get from the minimal model by constructing the descendants using \(L_{-k}\). The corresponding energy is the sum of the two independent energies

\[ E_{r; n^o, n^e} = e_{r,n^o} + e_{r,n^e} , \quad r = 3, 4 \]  

and this agrees with the equation \((4.26)\). To illustrate the construction of the eigenstates, we give below the three eigenvectors at level 2 for \(b_0 = 0\) obtained by direct diagonalization of \(I_3\) and \(I_4\),

\[ |[2], [0]\rangle = \sqrt{2} \left[ a_{-2} + \frac{1}{\sqrt{2}} (a_{-1}^2 + b_{-1}^2) \right] |0\rangle = [c_{-2} + c_{-1}^2 + c \rightarrow \bar{c}] |0\rangle \]  

\[ |[1, 1], [0]\rangle = \sqrt{2} \left[ -a_{-2} + \frac{1}{\sqrt{2}} (a_{-1}^2 + b_{-1}^2) \right] |0\rangle = [-c_{-2} + c_{-1}^2 + c \rightarrow \bar{c}] |0\rangle \]  

\[ |[1], [1]\rangle = 2 [a_{-1}^2 - b_{-1}^2] |0\rangle = c_{-1} \bar{c}_{-1} |0\rangle \]
They obey the following symmetry properties. Let us set
\[ g_n \text{ is to transpose the Young diagram} \]
and their eigenvalues are given by
\[ |n^o, n^e; q\rangle = S_n^o(c) S_n^e(\overline{c}) |q\rangle + S_n^e(\overline{c}) S_n^o(c) |q\rangle - q \, . \] (5.72)

5.4 Arbitrary \( g \)

The separation of the energy of the intermediate states into two independent parts (4.26) begs for an explanation. We have seen in the previous section that at \( g = 1 \) this separation originates in the separation of the Hamiltonian \( I_3 \) into two commuting parts. In this section we are going to investigate how the Hamiltonian \( I_3 \) can be written in terms of two independent bosons. First, we define the following one-component bosonic Calogero-Sutherland Hamiltonians [11, 37]
\[ \mathcal{I}_2(c) = \sum_{m>0} c_{-m} c_m \, , \] (5.73)
\[ \mathcal{I}_3^\pm(c; g) = (1 - g) \sum_{m>0} m c_{-m} c_m \pm \sqrt{g} \sum_{m,k>0} (c_{-m-k} c_m c_k + c_{m-k} c_m c_k) \, , \] (5.74)
\[ \mathcal{I}_4^\pm(c; g) = \left( \frac{3g}{2} - g^2 - 1 \right) \sum_{m>0} m^2 c_{-m} c_m - \frac{g}{4} \sum_{m_i \neq 0} : c_{m_1} c_{m_2} c_{m_3} c_{m_4} : \pm \] (5.75)
\[ \pm 3 \sqrt{g} (g - 1) \sum_{m, l>0} m (c_{-m-l} c_m c_l + c_{m-l} c_m c_l) \, . \]

They obey the following symmetry properties
\[ \mathcal{I}_m^+(c; g) = \mathcal{I}_m^-(c; g) \, , \quad m = 3, 4 \, , \]
\[ \mathcal{I}_3^+(c; g) = -g \mathcal{I}_3^-(c; 1/g) = -g \mathcal{I}_3^+(c; -1/g) \, , \]
\[ \mathcal{I}_4^+(c; g) = g^2 \mathcal{I}_4^-(c; 1/g) = g^2 \mathcal{I}_4^+(c; -1/g) \] (5.76)
and their eigenvalues are given by
\[ e_{2,n}(g) = \sum_i n_i = |n| \, , \] (5.77)
\[ e_{3,n}(g) = \sum_i n_i [n_i - g(2i - 1)] = b(n') - gb(n) + (1 - g) |n| = -g e_{3,n'}(1/g) \, , \] (5.78)
\[ e_{4,n}(g) = -\sum_i \left[ \left( n_i - g \left( i - \frac{1}{2} \right) \right)^3 + g^3 \left( i - \frac{1}{2} \right)^3 \right] - \frac{g^2}{4} \sum_i n_i = g^2 e_{4,n'}(1/g) \, . \] (5.79)

As it can be seen from the first equation (5.76), the eigenfunctions of \( \mathcal{I}_r^\pm \) can be related by the change of sign of the bosonic operators. Comparing to the case \( g = 1 \), we notice that the effect of this transformation is to transpose the Young diagram \( n \) which labels the eigenstate. We conclude by continuity in \( g \) that this property holds at any \( g \) and we have \( e_{3,n}(g) = e_{3,n'}(g) \).

In the classical limit \( g \to 0 \), the Hamiltonians (5.74) and (5.77) are the conserved quantities of the Benjamin-Ono equation. Let us set \( v = \sqrt{g} \partial \phi \) and \( \mathcal{I}_r \to g \mathcal{I}_r \); in the classical limit we obtain
\[ \mathcal{I}_2 \sim \int dx \frac{1}{2} v^2 \, , \] (5.80)
\[ \mathcal{I}_3 \sim \int dx \left( \frac{1}{3} v^3 + \frac{1}{2} v H(v_x) \right) \, , \] (5.81)
\[ \mathcal{I}_4 \sim \int dx \left( \frac{1}{4} v^4 + \frac{1}{4} v_x^2 + \frac{3}{4} v^2 H(v_x) \right) \, , \]
where \( v_x = \partial_x v \) and \( H(f) \) is the Hilbert transform of the function \( f \). \( \mathcal{L}_2 \sim L_0 \) corresponds to the stress-energy tensor. One can verify directly that the above quantities are integrals of motion of the Benjamin-Ono equation

\[
v = v v_x + \frac{1}{2} H(v_{xx}). \tag{5.82}
\]

The conservation of \( \mathcal{L}_4 \) relies on the identity \( \int df^3 = 3 \int df H(f)^2 \) applied to \( f = v_x \).

The full integral of motion \( I_3^\pm(g) \) for the (1) \( \otimes \) \( Vir(g) \) component from (4.34) can be written as

\[
I_3^\pm(g) = I_3^\pm(c; g) + I_3^\pm(\tilde{c}; g) \pm \sqrt{2g} (b_0 - \alpha_0)(I_2(c) - I_2(\tilde{c})) + \left( 1 - g \right) \left[ \left( 1 \mp 1 \right) \sum_{m>0} mc_{-m} c_m + \left( 1 \pm 1 \right) \sum_{m>0} mc_{-m} \tilde{c}_m \right]. \tag{5.83}
\]

The first line of this formula is an operator which can be diagonalized in the basis of Jack polynomials spanned by

\[
J_n^{1/\alpha}(\tilde{c}) \ J_n^{1/\alpha}(c) \ |q> \ J_n^{1/\alpha}(\tilde{c}) \ |2\alpha_0 - q>
\]

while the second line has a triangular structure in this basis, in the sense that it removes bosons of one type and it creates bosons of the other type. Here we have incorporated the reflexion property which is built in in (5.83) and which in this case exchanges the two copies of bosons and simultaneously reflects the charge, \( q \to -2\alpha_0 - q \).

Due to the triangularity property, we conclude that the energy can be written as a sum

\[
E_{3; n, n'}^\pm(g) = c_{3, n'}^\pm(g) + c_{3, n'}(g) + \sqrt{2g} (q - \alpha_0) (|n^o| - |n^e|).
\]

For the module of the identity \( g = 0 \), comparing with (4.26) we find that

\[
E_{3; n, n'}^\pm(g) = \mathcal{E}_A^\pm - \mathcal{E}_A^0 + \left( \frac{N - 2}{\alpha} \right) (\mathcal{P}_A - \mathcal{P}_A^0) + \left( M - 2 \right) (|n^e| + |n^o|),
\]

where we remind that \( \alpha = 1/(1-g) \). The terms depending on the total momentum come from the redefinition of the Hamiltonian, see for example formula (B.34). This relation proves the ansatz used in (4.21) and (4.22).

### 6 WA\( k \) theories

The duality obeyed by the conformal blocks was first discovered in [22] in the context of WA\( k \) \( (k+1, k+r) \) theories, which for \( r = 2 \) are related to \( \mathbb{Z}_k \) parafermions. For \( k = 2 \) these models coincide with the Virasoro models from the section 4 with \( g = (2+r)/3 \). When \( r \) is integer, the WA\( k \) \( (k+1, k+r) \) theories correspond to \( \mathbb{Z}_k^{(r)} \) parafermions considered in [21] [22] [31] [32] [33] [34]. The results in [22] generalize straightforwardly to any value of \( r \), not necessarily integer, in the same manner the results for the Ising CFT were extended to generic Virasoro models in the previous section. Again, the object under consideration is the dressed conformal block

\[
\mathcal{F}_{M,N}^{a,b}(w; z) \equiv \langle \sigma(w_1) \ldots \sigma(w_M) \Psi(z_1) \ldots \Psi(z_N) \rangle^{a,b} \prod_{1 \leq i < j} w_{ij}^{\tilde{r}} \prod_{i,j} (w_i - z_j)^{\frac{1}{2}} \prod_{1 \leq i < j} z_{ij}^{\tilde{r}} \tag{6.1}
\]

where now \( \sigma(w) \) and \( \Psi(z) \) represent the primary fields \( \Phi_{1,1,2,1,1}(w) \) and \( \Phi_{1,2,1,2,1}(z) \) with conformal dimensions \( \tilde{r}(k-1)/2k \) and \( r(k-1)/2k \) respectively, where \( \tilde{r} \) is implicitly defined in equation (6.5) below.

As it was shown in reference [22], the dressed conformal block defined in equation (6.1) obeys the second order differential equation

\[
\alpha \ h^a(z) \mathcal{F}_{M,N}^{a,b}(w; z) = \tilde{\alpha} \ h^{\tilde{a}}(w) \mathcal{F}_{M,N}^{a,b}(w; z) \tag{6.2}
\]

where \( h^a(z) \) and \( h^{\tilde{a}}(w) \) are defined in terms of two differential Calogero-Sutherland operators

\[
h^a(z) = \mathcal{H}^a(z) - \mathcal{E}_0^a + \left( \frac{N - k}{\alpha} - 1 \right) [\mathcal{P}(z) - \mathcal{P}_0] - \frac{NM(M-k)}{k^2}, \tag{6.3}
\]

\[
h^{\tilde{a}}(w) = \mathcal{H}^{\tilde{a}}(w) - \mathcal{E}_0^{\tilde{a}} + \left( \frac{M - k}{\alpha} - 1 \right) [\mathcal{P}(w) - \mathcal{P}_0] - \frac{NM(N-k)}{k^2}. \tag{6.4}
\]
The coupling constant takes now the values
\[ \alpha = -\frac{k+1}{r-1}, \quad \tilde{\alpha} = \frac{k+r}{r-1}, \quad \text{and} \quad g = -\frac{\tilde{\alpha}}{\alpha} = \frac{k+r}{k+1} = \frac{k+1}{k+r}. \]  
(6.5)

The constants \( \mathcal{E}_0^\alpha \) and \( \mathcal{P}_0 \) are given by
\[ \mathcal{E}_0^\alpha = \mathcal{E}_{\lambda^0} = \frac{rN(N-k)[2Nr + k^2(1-2r) + k(N-r+Nr)]}{6k^2(k+1)}, \quad \mathcal{P}_0 = \frac{rN(N-k)}{2k}, \]  
(6.6)
while \( \mathcal{E}_{\tilde{\alpha}}^\alpha \) and \( \mathcal{P}_0^\prime \) are given by similar expressions with \( r \to \tilde{r} \), which is equivalent to \( g \to g^{-1} \), and \( N \to M \). The degree of homogeneity of \( \mathcal{F}_{M,N}^{a,b}(w;z) \) in both the variables \( w \) and \( z \) is
\[ \mathcal{P}(z) + \mathcal{P}(w) = \frac{rN(N-k)}{2k} + \frac{\tilde{r}M(M-k)}{2k} + \frac{MN}{k}. \]  
(6.7)

In the following we suppose that both \( M \) and \( N \) are divisible by \( k \), which insures that the conformal block (6.1) is non-zero. The duality property (6.2) implies that the conformal block (6.1) can be expanded on eigenfunctions of the dual Calogero-Sutherland Hamiltonians similarly to (4.13),
\[ \mathcal{F}_{M,N}^{a,b}(w;z) = \sum_\lambda \mathcal{F}_{\lambda^0}^{\tilde{\alpha},a}(w) \mathcal{F}_{\lambda^0}^{\tilde{\alpha},b}(z). \]  
(6.8)

The lowest eigenstate of the Hamiltonian \( \hbar \tilde{\alpha}(w) \) is characterized now by the quantum numbers
\[ \lambda_{k-j+1}^0 = \ldots = \lambda_{kj}^0 = \tilde{r} \left( \frac{M}{k} - j \right), \quad j = 1, \ldots, M/k. \]  
(6.9)
and it corresponds under the duality to the maximum “partition” \( \Lambda^0 \) defined as
\[ \Lambda_i^0 = \lambda_i^0 + \frac{M}{k}, \quad i = 1, \ldots, N \]
(6.10)
\[ \lambda^0_{k-i+1} = \ldots = \lambda_{k-i}^0 = r \left( \frac{N}{k} - i \right), \quad i = 1, \ldots, N/k. \]

Generically, the sets \( \lambda \) and \( \lambda' \) are related to each other through a set of \( k \) partitions \( n^{(p)} \) and their duals \( n'^{(p)} \), with \( p = 1, \ldots, k, \)
\[ \lambda_{ki-k+p} = \Lambda_{ki-k+p} - n^{(k-p+1)}_{N/k+i+1}, \quad \lambda'_{kj-k+p} = \lambda'_{kj-k+p} + n'^{(p)}_j, \quad p = 1, \ldots, k. \]  
(6.11)

Expressed in terms of the partitions \( n^{(p)} \) and \( n'^{(p)} \), the energies of the intermediate state in the expansion (6.8) are
\[ \mathcal{E}_\lambda^\alpha - \mathcal{E}_{\lambda^0}^\alpha = \sum_{p=1}^k \left[ b(n^{(p)}) - g b(n^{(p)}) \right] + \sum_{p=1}^k \left( 1 - g \right) (N - 2(p - 1)) - \frac{2M}{k} + g \left| n^{(p)} \right|. \]  
(6.12)
and
\[ \mathcal{E}_\lambda^{\tilde{\alpha}} - \mathcal{E}_{\lambda^0}^{\tilde{\alpha}} = \sum_{p=1}^k \left[ b(n^{(p)}) - \frac{1}{g} b(n'^{(p)}) \right] + \sum_{p=1}^k \left[ 2M \frac{r}{k} + (2 - g^{-1}) + (1 - g^{-1})(M + 2(k - p)) \right] \left| n'^{(p)} \right|. \]  
(6.13)

where \( b(n) \) and \( |n| \) are defined in (6.24). The two dual energies sum up to a constant which does not depend on the particular state \( n^{(p)} \), as implied by the formula (6.2),
\[ \mathcal{E}_\lambda^\alpha - \mathcal{E}_{\lambda^0}^\alpha + g (\mathcal{E}_\lambda^{\tilde{\alpha}} - \mathcal{E}_{\lambda^0}^{\tilde{\alpha}}) + \left( \frac{N-k}{\alpha} - 1 \right) (\mathcal{P}_\lambda - \mathcal{P}_0) + g \left( \frac{M-k}{\tilde{\alpha}} - 1 \right) (\mathcal{P}_{\lambda'} - \mathcal{P}_{0'}) = \]
\[ = \mathcal{E}_{\lambda^0}^\alpha - \mathcal{E}_{\lambda^0}^{\tilde{\alpha}} + \frac{NM}{k} \left( \frac{N-k}{\alpha} - 1 \right) = \frac{NM(M-k)}{k^2} + gMN(N-2). \]  
(6.14)

Therefore, the only difference with the Virasoro model from section 4 is the appearance in the intermediate states of \( k \) partitions. In the following, we will explain this structure via the bosonisation.
6.1 Bosonisation of the WA\(_{k-1}\) theories

The WA\(_{k-1}\) theories can be constructed with the help of a \(k - 1\) component bosonic field. Let \(h_i\) with \(i = 1, \ldots, k\) be the weights in the fundamental representation of the \(su(k)\) algebra,

\[
\vec{h}_1 = \left( \frac{k-1}{k}, \frac{-1}{k}, \ldots, \frac{-1}{k} \right), \quad \ldots, \quad \vec{h}_k = \left( -\frac{1}{k}, \frac{k-3}{2}, \ldots, \frac{-1}{k} \right).
\]

The fundamental weights of \(su(k)\) are

\[
\vec{\omega}_i = \sum_{j=1}^i \vec{h}_j \quad \text{and} \quad \rho = \sum_{j=1}^k \vec{\omega}_j = \left( \frac{k-1}{2}, \frac{k-3}{2}, \ldots, \frac{-1}{2} \right).
\]

Let us first consider \(k\) copies of bosonic fields \(\vec{\phi} = (\phi^1, \ldots, \phi^k)\) with normalization \(\langle \phi^i(z)\phi^j(0) \rangle = -\delta_{ij} \log z\). We redefine the fields as

\[
\phi_0 = \frac{1}{k} \sum_{i=1}^k \phi^i, \quad \phi_i = \vec{h}_i \phi = \phi^i - \phi_0, \quad i = 1, \ldots, k
\]

The \(k\) fields \(\phi_i\) are not independent since \(\sum_{i=1}^k \phi_i = 0\). They are the fields that effectively enter the bosonisation of the WA\(_{k-1}\) theory. The diagonal field \(\phi_0\) decouples at this stage, but it is convenient to keep it for later purpose. It will appear in the next subsection in guise of the \(u(1)\) field. We have

\[
\langle \phi_0(z)\phi_0(0) \rangle = -\frac{1}{k} \log z, \quad \langle \phi_i(z)\phi_0(0) \rangle = 0, \quad i = 1, \ldots, k
\]

\[
\langle \phi_i(z)\phi_j(0) \rangle = -\left( \delta_{ij} - \frac{1}{k} \right) \log z.
\]

The fields \(\phi_i\) generate a conformal field energy with stress-energy tensor

\[
T(z) = \sum_{i<j} : \partial \phi_i \partial \phi_j : -i\alpha_0 \sqrt{2} \sum_j (j-1) \partial^2 \phi_j = -\frac{1}{2} \sum_{j=1}^k : (\partial \phi^j)^2 : + \frac{k}{2} (\partial \phi_0)^2 : + i\alpha_0 \sqrt{2} \rho \partial^2 \vec{\phi}
\]

and a spin 3 current \(\vec{W}(z)\) given by\(^7\)

\[
i\vec{W}(z) = \sum_{i<j<l} : \partial \phi_i \partial \phi_j \partial \phi_l : -\alpha_0 \sqrt{2} \sum_{j<l} [(l-1) : \partial^2 \phi_j \partial \phi_l : + (j-2) : \partial \phi_l \partial^2 \phi_j :] + \alpha_0^2 \sum_j (j-1)(j-2) \partial^3 \phi_j + \frac{i\alpha_0(k-2)}{\sqrt{2}} \partial T(z).
\]

The vertex operators

\[V_{\vec{\beta}}(z) = : e^{i\vec{\beta} \vec{\phi}(z)}:
\]

are primary fields of the theory, with conformal dimension given by\(^8\)

\[
\Delta_{\vec{\beta}} = \frac{1}{2} \vec{\beta} \cdot (\vec{\beta} - 2\vec{\alpha}_0), \quad \vec{\alpha}_0 = \alpha_0 \sqrt{2} \vec{\rho}.
\]

---

\(^7\)The usual normalization is such that \(\langle W(1)W(0) \rangle = c/3\), so that \(\vec{W}(z) = \sqrt{\frac{2}{k+1}} ((k+2)g-k)((k+2)-k)W(z)\).

\(^8\) If the vector \(\vec{\beta}\) is not orthogonal to the vector \((1, \ldots, 1)\), the vertex operator will have an extra \(u(1)\) part, since it will contain \(\phi_0\).
The degenerate fields of the theory, denoted by $\Phi_{(n_1,\ldots,n_k)}$, are associated to the vertex operators with charges

$$\tilde{\beta} = \frac{1}{\sqrt{2}} \sum_{i=1}^{k-1} [(1-n_i)\alpha_+ + (1-n_i')\alpha_-] \tilde{\omega}_i$$

(6.23)

where

$$\alpha_+ = \sqrt{\frac{g}{2}}, \quad \alpha_- = -\sqrt{\frac{g}{2}}, \quad 2\alpha_0 = \alpha_+ + \alpha_-.$$  

(6.24)

so that the fundamental fields $\Phi_{(1,\ldots,1,2,\ldots,1)}$ and $\Phi_{(1,\ldots,1,2,\ldots,1,1)}$ are represented by the vertex operators $V_{1/\sqrt{g}\omega_{-1}}(z)$ and $V_{\sqrt{g}\omega_{-1}}(z)$ respectively, with conformal dimension

$$\eta = \frac{k-1}{2k} \left[ k + \frac{1}{2} \right] = \frac{r(k-1)}{2k}, \quad h = \frac{k-1}{2k} \left[ (k+1)g - k \right] = \frac{r(k-1)}{2k}.$$  

(6.25)

The fields $\Phi_{(1,\ldots,1,2,\ldots,1,1)}$ have generically two fusion channels with themselves,

$$\Phi_{(1,\ldots,1,2,\ldots,1,1)}(z_1)\Phi_{(1,\ldots,1,2,\ldots,1,1)}(z_2) \sim \Phi_{(1,\ldots,1,2,\ldots,1)}(z_2) + \frac{\Phi_{(1,\ldots,1,3,\ldots,1)}(z_2)}{(z_1-z_2)^{2h-h}}.$$  

(6.26)

so that the leading short distance singularity is characterized by the power $2h-h_a = r/k$. This explains the powers which were used in dressing the conformal block (6.1) to remove the short distance singularities.

Let us now consider the $u(1)$ current $J(z)$ which we identify with the diagonal field $J(z) = i\sqrt{k} \partial \phi_0(z)$, We dress the fundamental fields $\Phi_{1,\ldots,1,2,\ldots,1,\ldots,1}$ and $\Phi_{1,\ldots,1,2,\ldots,1,\ldots,1}$ by vertex operators, defining

$$V(z) \equiv \Phi_{1,\ldots,1,2,\ldots,1,\ldots,1}(z) : e^{i\sqrt{g}\phi_0(z)} :,$$

$$V(w) \equiv \Phi_{1,\ldots,1,2,\ldots,1,\ldots,1}(w) : e^{i\sqrt{g}\phi_0(w)} :.$$  

(6.27)

Choosing appropriately the bosonic representative for the fundamental fields, we can write

$$V(z) \sim e^{i\sqrt{g}\phi_1(z)}e^{i\sqrt{g}\phi_0(z)} : = e^{i\sqrt{g}\phi^1(z)} :,$$

$$V(w) \sim e^{i\sqrt{g}\phi_1(w)}e^{i\sqrt{g}\phi_0(w)} : = e^{i\sqrt{g}\phi^1(w)} :,$$

(6.28)

and which again can justify the mutual separation of the action of the Calogero-Sutherland Hamiltonians on the $u(1)$ dressed conformal blocks (6.1). A similar basis of bosonic fields was used recently in [50] to study the appearance of the $W_{1+\infty}$ algebra in the context of the $su(3)$ AGT relationship.

### 6.2 The $W_{A_k}$ theories at $g = 1$

The action of the Calogero-Sutherland Hamiltonians on the conformal blocks can be again transferred to an action on the Hilbert space of the $u(1) \otimes W_{A_k-1}$ as it does in the case of minimal models, cf. section (5.2). When $g = 1$ the first non-trivial conserved quantity $I_3$ has the expression

$$I_3^\pm(1) = \pm \frac{1}{\sqrt{k}} \left[ \sum_{m \neq 0} a_{-m}L_m + \sum_{m,k \geq 1} (a_{-m-k}a_ma_k + a_{-m}a_{-m-k}) \right] \pm \hat{W}_0$$

(6.29)

and can be written as a sum of $k$ independent bosonic Calogero-Sutherland Hamiltonians. The new ingredient $\hat{W}_0$ is the zero mode of the operator $\hat{W}(z)$

$$i\hat{W}(z) = \frac{1}{3} \sum_{j=1}^k : (\partial \phi_j)^3 : = \sum_{j=1}^k \left[ \frac{1}{3} : (\partial \phi)^3 : - : (\partial \phi)^2(\partial \phi_0) : + \frac{2k}{3} : (\partial \phi_0)^3 : \right],$$

(6.30)

while the Virasoro generators $L_m$ are the Fourier modes of the stress-energy tensor

$$T(z) = -\frac{1}{2} \sum_{j=1}^k : (\partial \phi_j)^2 : + \frac{k}{2} : (\partial \phi_0)^2 :.$$  

(6.31)
Let us now identify the $u(1)$ current with the diagonal bosonic field $J = i\sqrt{k}\partial \phi_0(z)$, with Fourier modes $a_m = \frac{1}{\sqrt{k}} \sum_{j=1}^k \epsilon_j^m$. It is now straightforward to show that $I_3$ can be written as a sum of $k$ decoupled Hamiltonians depending on the $k$ independent bosons $c_m^j$

$$I_3^\pm(1) = \pm \sum_{j=1}^k \mathcal{I}_3^j(c^j) \pm 2 \sum_{j=1}^k (\tilde{h}_j \tilde{c}_0) \mathcal{I}_2(c^j),$$

(6.32)

with the only coupling between the $k$ bosonic copies being realized by the zero modes $c_0^j$ in the second term. This decomposition generalizes the result of Belavin and Belavin [36] to the case of $W$ algebras with $g = 1$, and it justifies the structure of the eigenenergies of the intermediate states (6.12) as a sum over $k$ Young tableaux.

### 6.3 Arbitrary $g$

When $g \neq 1$, the integral of motion $I_3$ of the $W$ theories conserves the same triangular structure as the one described in section 5.4. Its expression is given by

$$I_3^\pm(g) = k(1 - g) \sum_{m \geq 1} ma_{-m}a_m + 2 \sqrt{g} \sum_{m \neq 0} a_{-m}L_m + \sqrt{g} \sum_{m, k \geq 1} (a_{-m-k}a_ka_k + a_{-m}a_{-k}a_{m+k}) \pm \sqrt{g}\tilde{W}_0 .$$

(6.33)

After expressing the zero mode of the $W(z)$ current in terms of the bosonic fields, one finds that

$$I_3^\pm(g) = \sqrt{g} I_3(1) + k(1 - g) \sum_{m \geq 1} ma_{-m}a_m + (1 - g) \sum_{j \neq l} m : c_{-m}^j c_m^j : + \text{ terms with zero modes} =$$

$$= \sum_{j=1}^k \mathcal{I}_3^j(c^j; g) \pm 2 \sqrt{g} \sum_{j=1}^k \tilde{h}_j \cdot (\tilde{c}_0 - \bar{\alpha}_0) \mathcal{I}_2(c^j) \mp \sqrt{g} \sum_{j} (\tilde{h}_j \cdot \bar{\alpha}_0)(\tilde{h}_j \cdot \bar{\alpha}_0)(\tilde{h}_j \cdot (\bar{c}_0 - \bar{\alpha}_0))$$

$$+ (1 - g) \sum_{m \geq 1} \left[ \left( 1 \pm 1 \right) \sum_{j \neq l} m : c_{-m}^j c_m^j : + (1 \mp 1) \sum_{j \geq l} m : c_{-m}^j c_m^j : \right] ,$$

(6.34)

where $\bar{\alpha}_0 = \sqrt{2}\alpha_0\bar{\rho}$. On states in the module of the identity, the eigenvalues of $I_3^+(g)$ are given by

$$E_{3,n(p)}^+(g) = \sum_{p=1}^k E_{3,n(p)}^+(g) + (1 - g) \sum_{p=1}^k (k + 1 - 2p)|n(p)| ,$$

(6.35)

where we have ordered the partitions in the reverse order, in the sense that the partition $n(p)$ corresponds to the boson copy $c^{k-p}$. This eigenenergy agrees, up to a momentum-depending shift in the Hamiltonian, with the one in (6.12),

$$E_{3,n(p)}^+(g) = E_{3,n(p)}^+ + \left( \frac{N - k}{\alpha} \right) \left( \mathcal{P}_\lambda - \mathcal{P}_{\lambda'} \right) + \frac{2(M - k)}{k} \sum_{p=1}^k |n(p)| .$$

(6.36)

This proves the identification of the labels of the ”partitions” $\lambda$ in terms of $k$ partitions $n(p)$ which was done in (6.11).

### 7 Conclusion and outlook

In this paper we have studied the integrable structure of the $u(1) \otimes Vir(g)$ and, more general, of the $u(1) \otimes WA_{k-1}$ CFTs. Our starting point is the action of the Calogero-Sutherland Hamiltonian on the conformal blocs of these theories which contains second order degenerate fields. Dual degenerate field are
associated to Calogero-Sutherland Hamiltonians with dual coupling constants. Once translated on arbitrary
descendant fields inserted in the correlation functions, the action of the Calogero-Sutherland Hamiltonians
generates an action on the Hilbert space of the theory. This action corresponds to the action of the integrals
of motion found in refs. [28] and [55]. The basis associated to these integrals of motion were used in
refs. [28] and [55] to give a proof of the AGT conjecture [29] relating the Nekrasov’s instanton partition
function for supersymmetric quiver gauge theories to Liouville conformal blocks (or to the conformal blocks
of the WA_{k-1} theory). Using bosonisation of the corresponding theories, we show that the action of the
Calogero-Sutherland integrals of motion on the Hilbert space can be written as a sum of k copies of Calogero-
Sutherland bosonic Hamiltonians coupled by an interaction term which is triangular in the bosonic basis.
This explains why the spectrum of the integrals of motion is the sum of the spectra of k Calogero-Sutherland
Hamiltonians with coupling constant g (or, dually, 1/g) and it is indexed by k partitions. The advantage of
our approach is to show that the integrals of motion correspond to a unique Calogero-Sutherland differential
operator with coupling constant 1 − g, and that the associated eigenfunctions are generically non-polynomial.
In some particular cases, when g = (k + r)/(k + 1) with k and r integers, the associated eigenfunctions are
Jack polynomial with parameter α = −(k + 1)/(r − 1). These polynomials give electron eigenfunctions of
the Fractional Quantum Hall Effect (FQHE) with pairing properties [21, 22].

It would be interesting to explore further the non-polynomial eigenfunctions of the Calogero-Sutherland
model which are associated with the conformal blocks, and their link with the bosonic states in their Jack
polynomial representation.

One of the most interesting yet unsolved problem is to unravel the integrable structure which is behind
the integrals of motion which we identified in this work. We have obtained that the integrals of motion are
associated with particular null vectors which are descendants of the null vector at level two. It would be
interesting to find a representation of the monodromy matrix in the framework of the CFT, similar to that
obtained by Bazhanov, Lukyanov and Zamolodchikov [51] for Vir(g).

Note: On the final stage of the preparation of the manuscript we have learned that results concerning the
integrals of motion \( I_n \) and the associated \( R \) matrix were obtained by Davesh Maulik and Andrei Okounkov
[52]. Our results partially overlap with theirs, in particular concerning the triangular expansion of \( I_3 \),
our formulas (5.83) and (6.34). An expression similar to (5.83) also appeared recently in [54]. A \( q \)-version
of the AGT relation was given in [54]. The proof of the AGT conjecture for \( U(k) \) quiver gauge theories was
given by Fateev and Litvinov in [55], where they used the same basis of the integrals of motion as the one
in our section 6.

Acknowledgements: V.P and D.S. thank to Andrei Okounkov for discussions and for sharing their
unpublished work. We acknowledge discussions with A.A. Belavin, Vl. Dotsenko, B. Feigin, A.A. Litvinov,

Netherlands.

A  \( u(1) \otimes \) Ising conformal field theory

In section 4 we considered the \( u(1) \otimes Vir(g) \) algebra and the corresponding family of CS conformal block
eigenfunctions. In particular we derived the CS eigenvalue formulas (4.25) which show how the duality
\( g \to 1/g \) of the CS model works for non-polynomial eigenfunctions. The formulas (4.25) have been initially
guessed on the basis of the results concerning the \( u(1) \otimes Vir(4/3) \) algebra, that is to say the \( u(1) \otimes \) Ising
algebra. This case is particularly useful because the conformal blocks of free fermion fields (which represent
one side of the duality) are given by certain Jack polynomials with pairing properties. It is interesting to
remark that these properties have a direct relevance in the study of the FQHE. In this appendix we show in
full detail that the formulas (4.25) can be derived, for the Ising case, by using, together with the (4.7), the
pairing properties of the fermionic conformal blocks.

A.1 Ising primary fields

The Ising model is the unitary minimal model of the Virasoro algebra (3.2) with central charge \( c = 1/2 \). It
presents a finite number of operators which close under operator algebra: besides the identity I, there are only
the two Virasoro primary fields \( \Phi_{(1|2)} \) and \( \Phi_{(2|1)} \) with conformal dimension \( \Delta_{(1|2)} = 1/2 \) and \( \Delta_{(2|1)} = 1/16 \). In our notations, this fixes \( g = 4/3 \). The fields \( \Phi_{(1|2)} \) and \( \Phi_{(2|1)} \) correspond to the free fermion field \( \Psi \):

\[
\Psi \equiv \Phi_{(1|2)},
\]

and to the spin operator \( \sigma \):

\[
\sigma \equiv \Phi_{(2|1)}.
\]

Their fusion relations read

\[
\Psi(z)\Psi(w) = \frac{1}{z - w} I, \quad (A.2)
\]

\[
\sigma(z)\sigma(w) = \frac{C^\sigma_{\sigma,\sigma}}{(z - w)^{1/8}} I + \frac{C^\sigma_{\sigma,\psi}}{(z - w)^{-3/8}} \Psi(w), \quad (A.3)
\]

\[
\sigma(z)\Psi(w) = \frac{C^\sigma_{\sigma,\psi}}{(z - w)^{1/2}} \sigma(w), \quad (A.4)
\]

where the \( C^Z_{X,Y} \) are the structure constants of the operator algebra.

### A.2 Relation with Calogero-Sutherland model

**Conformal block of \( N \) free fermions**: Consider first the conformal block of \( N \) free fermions:

\[
\langle \Psi(z_1) \ldots \Psi(z_N) \rangle. \quad (A.5)
\]

This correlator can of course be easily computed by using the Wick theorem, \( \langle \Psi(z_1) \ldots \Psi(z_N) \rangle = \text{Pf}(1/z_{ij}) \), where Pf(\( M_{ij} \)) if the Pfaffian of the matrix \( M_{ij} \). The \( N \) fermion fields \( \Psi \) degenerate second order fields and their correlation function satisfies a system of \( N \) second order equations (3.11). On can recast these equations in the following way:

\[
\sum_{i=1}^N z_i^2 \partial_i^{4/3} \langle \Psi(z_1) \ldots \Psi(z_N) \rangle = 0. \quad (A.6)
\]

Using the Ward identities satisfied by the conformal blocks

\[
\sum_{i=1}^N \partial_i \langle \Psi(z_1) \ldots \Psi(z_N) \rangle = 0
\]

\[
\sum_{i=1}^N \left( z_i \partial_i + \frac{1}{2} \right) \langle \Psi(z_1) \ldots \Psi(z_N) \rangle = 0, \quad (A.7)
\]

one obtains from the equation (A.6):

\[
\left[ \sum_{i=1}^N (z_i \partial_i)^2 - \frac{4}{3} \sum_{i<j} z_i z_j \frac{z_i}{z_j} + \frac{2}{3} \sum_{i<j} z_i z_j (z_i \partial_i - z_j \partial_j) - \frac{2N}{3} \right] \langle \Psi(z_1) \ldots \Psi(z_N) \rangle = 0. \quad (A.8)
\]

One can recognize in the above the Calogero-Sutherland Hamiltonian in the form (2.9) with \( \gamma = 2/3 \) and \( g = 4/3 \). The function

\[
\Psi(z) \equiv \prod_{i<j} z_i^{2/3} \text{Pf}(1/z_{ij}) \quad (A.9)
\]

is then eigenfunction of (2.6) with coupling \( g = 4/3 \). It is easy to convince oneself that

\[
\Psi(z) = \prod_{i<j} z_i^{-1/3} F(z) = \prod_{i<j} z_i^{1-g} F(z), \quad (A.10)
\]

with \( F(z) \) regular at \( z_i \to z_j \), which means that \( \Psi(z) \) is subject to the second type of boundary conditions \( \Psi^- (z) \) in the terminology of equation (2.11).
Conformal blocks of $M$ spin operators $\sigma$ : Analogously, we could consider the correlation function of $M$ fields $\sigma$:

$$\langle \sigma(z_1) \ldots \sigma(z_M) \rangle_a$$

(A.11)

where $a = 1, \ldots, 2^{M/2-1}$ is the conformal block index. Indeed, from the fusions (A.3)-(A.4), there are $2^{M/2-1}$ different conformal blocks corresponding to the function (A.11).

Figure 2: A diagram representing the conformal block of $\sigma$ fields for $M = 6$. For each diagram there are $M/2 - 1$ fields $X$ which can correspond to the $I$ or to the $\psi$ field, with $X = I$ or $X = \psi$. The total number of possible conformal blocks is then $2^{M/2-1}$.

Again, using the $M$ second order differential equations (3.11) and the conformal Ward identities, the conformal block (A.11) can be shown to satisfy the equation:

$$\sum_{i=1}^{M} (z_i \partial_i)^2 - \frac{3}{32} \sum_{i<j} \frac{z_i z_j}{z_{ij}^2} + \frac{3}{8} \sum_{i<j} \frac{z_i + z_j}{z_{ij}} (z_i \partial_i - z_j \partial_j) - \frac{3M}{64} \langle \sigma(z_1) \ldots \sigma(z_N) \rangle_a = 0,$$

(A.12)

which corresponds to the operator (2.9) for $\gamma = 3/8$ and $g = 3/4$. An eigenfunction of (2.6) with coupling $g = 3/4$ is then obtained by setting:

$$\Psi(z)_a \equiv \prod_{i<j} z_{ij}^{3/8} \langle \sigma(z_1) \ldots \sigma(z_M) \rangle_a.$$

(A.13)

It is interesting to notice that the eigenvalue associated to the eigenfunctions $\Psi(z)_a$ does not depend on the particular conformal block index $a$. Generally, by using the (A.3) into (A.13), one has that:

$$\Psi(z)_a \sim c_{a1} z_{ij}^{1/4} + c_{a2} z_{ij}^{3/4} \quad \text{for} \quad z_i \rightarrow z_j.$$

(A.14)

The possible asymptotic behavior characterizing the eigenfunctions of (2.6) with $g = 3/4$, see (2.10), are then associated to the two fusion channels in (A.3). The exponents characterizing the two boundary condition are given by $1 - g = 1/4$ and $g = 3/4$. The first exponent is smaller, so we can write

$$\Psi(z)_a = \prod_{i<j} z_{ij}^{1/4} F(z)_a$$

(A.15)

with $F(z)_a \sim c_{a1} + c_{a2} \sqrt{z_{ij}}$ for $z_i \rightarrow z_j$.

Each conformal block $\Psi(z)_a$ is characterized by having a given configuration of boundary conditions. In this respect, consider for instance the simplest non trivial case, i.e. with $N = 4$. Here one has two conformal blocks, $\Psi(z)_a$ with $a = 1, 2$. One conformal block, say $\Psi(z)_1$, can be chosen such that:

$$\begin{align*}
\Psi(z)_1 & \sim_{z_1 \rightarrow z_2} z_{12}^{1/4} \\
\Psi(z)_1 & \sim_{z_1 \rightarrow z_3} c_{11} z_{13}^{1/4} + c_{12} z_{13}^{3/4}
\end{align*}$$

$$\begin{align*}
\Psi(z)_1 & \sim_{z_1 \rightarrow z_4} \frac{1}{z_{34}^{1/4}} \\
\Psi(z)_1 & \sim_{z_1 \rightarrow z_2} c_{11} \frac{1}{z_{24}^{1/4}} + c_{12} \frac{1}{z_{24}^{3/4}}
\end{align*}$$

24
while the other behave as:

\[
\begin{align*}
\Psi(z)_2 \sim z_1 \rightarrow z_2 z_1^{3/4} \\
\Psi(z)_2 \sim z_1 \rightarrow z_3 c_21 z_1^{1/4} + c_{22} z_1^{3/4} \\
\Psi(z)_2 \sim z_2 \rightarrow z_4 z_2^{3/4} \\
\Psi(z)_2 \sim z_2 \rightarrow z_3 c_{21} z_2^{1/4} + c_{22} z_2^{3/4}
\end{align*}
\]

where the \( c_{nm} \) are some constants. A detailed discussion about the possible boundary conditions configurations associated to conformal block correlator has been done in \([20]\).

### A.3 Clustering polynomials and admissible partitions

Let us come back for a moment to the fermionic conformal blocks. The function associated to conformal block correlator has been done in \([20]\).

\[
i_{ij} \equiv (\Psi(z_1) \cdots \Psi(z_N))
\]

is a function regular when \( z_{ij} \rightarrow 0 \), monovalued, symmetric of total degree \( N(N-2)/2 \), therefore it should be a symmetric polynomial. It is an eigenfunction of the CS Hamiltonian \([2, 12]\) with \( \alpha = 1/(1-g) = -3 \), therefore it should be a Jack polynomial with a negative coupling constant. By inspection it is equal to \( J^{\lambda_0}_1(z) \) where \( \lambda_0 \) is the partition

\[
\lambda_0 = [N-2, N-2, N-4, N-4, \ldots, 0, 0].
\]

It is interesting to point out that the polynomial \( J^{\lambda_0}_1(z) \) does not vanish when two variables are at the same point but vanishes with power 2 when the third particles approaches a cluster of two. Due to this property, this polynomial is the zero-energy eigenstate of model 3-body Hamiltonian and thus it has been considered as a good trial many-body wavefunctions for fractional quantum Hall systems.

More generally, Jack polynomials with \((k, r)\)-clustering properties appear in the WA\(_{k-1}(k+1, k+r)\) theories; these polynomials vanish with a power \( r \) when at least \( k+1 \) particles come to the same point. A characterization of symmetric polynomials with clustering properties was initiated in the work of Feigin \emph{et al.} \([45, 46]\). Let \( k, r \) be positive integer such that \( k+1 \) and \( r-1 \) are co-prime. A partition \( \lambda \) is said to be \((k, r, N)\)-admissible if it satisfies the following condition:

\[
\lambda_i - \lambda_{i+k} \geq r \quad (1 \leq i \leq N-k).
\]

The \( \lambda_0 \) is then a \((2, 2, N)\) admissible partition. Given a \((k, r, N)\)-admissible partition \( \lambda \) Feigin \emph{et al.} \([45]\) showed that:

- the coefficients \( c_{\lambda M}(\alpha) \) do not have a pole for the particular negative value \( \alpha = - (k+1)/(r-1) \).
- the Jack polynomial \( J^{(k+1)/(r-1)}(z_1, \cdots, z_n) \) vanishes when \( z_1 = z_2 = \cdots = z_{k+1} \).

The space spanned by the Jack polynomials \( J^{(k+1)/(r-1)}(z_1, \cdots, z_N) \) for all \((k, r, N)\)-admissible partitions \( \lambda \) coincides with the space of symmetric polynomials satisfying the \((k, r)\) clusterings.

### A.4 Duality and separation

Let us now consider the function \([4, 2]\) for the Ising case:

\[
\mathcal{F}_{M,N}^{a}(w; z) \equiv \langle \sigma(w_1) \cdots \sigma(w_M) \psi(z_1) \cdots \psi(z_N) \rangle_a \prod_{1 \leq i < j} w_{ij}^{1/8} \prod_{i,j} (w_i - z_j)^{1/2} \prod_{1 \leq i < j} z_{ij}. \tag{A.19}
\]

Note that, with respect to the \([4, 2]\), we have here only one index \( a \) which runs over the possible 2\(^{M/2-1}\) possible independent conformal blocks (see also the \([4, 2]\) below). This is because the \( \Psi \) field correlators have an Abelian monodromy. The function \( \mathcal{F}_{M,N}^{a}(w; z) \), which has been introduced to describe the excited

\(^9\) \( N \) should be even, otherwise the conformal block vanishes.
$M$–quasihole wavefunction for the paired fractional quantum Hall state \cite{25,26}, has been computed exactly in \cite{56,57} (note that it vanishes for $M$ odd).

Because of the fusions \eqref{A.2}-\eqref{A.4}, the factors $\prod_{i<j} z_{ij}$ and $\prod_{i,j} (w_i - z_j)^{1/2}$ insure the function $F_{M,N}^a(w; z)$ to be a symmetric polynomial in the $z$ variables. In particular the factor $\prod_{i,j} (w_i - z_j)^{1/2}$ renders the variables $z$ and $w$ mutually local. The factor $\prod_{i<j} w_{ij}^{1/2}$ suppresses the divergence as $w_{ij} \to 0$. It is rather easy to show from the fusion \eqref{A.2} that the function $F_{M,N}^a(w; z)$ satisfies the following $(2,2)$–clustering properties:

$$F_{M,N}^a(w, z_1 = z_2 = Z, z_3, z_4, \cdots, z_N) = \prod_{i=1}^{M} (w_i - Z) \prod_{i=3}^{N} (Z - z_i)^2 F_{M,N-2}^a(w, z_3, z_4, \cdots, z_N). \quad \text{(A.20)}$$

The function $F_{M,N}^a(w; z)$ can in general be expanded in symmetric polynomials of $z$, each of which satisfies the $(2,2)$-clustering condition and has total degree $D$ such that:

$$\frac{N(N-2)}{2} \leq D \leq \frac{N(N-2)}{2} + NM. \quad \text{(A.21)}$$

This can be seen, for instance, from the conformal block $F_{M,N}^1(w; z)$ corresponding to the case where all the $\sigma_i$ fuse into the identity. In the limit $w_{2n} \to w_{2n-1} = W_n$, $n = 1, \ldots, M/2$, one has from \eqref{A.3}:

$$F_{M,N}^1(w_1, \ldots, w_M, z) \to \prod_{i=1}^{M/2} \prod_{j=1}^{N} (z_j - W_i) J_{\lambda_0}^{-3}(z) \quad \text{for} \quad w_{2n}, w_{2n-1} \to W_n \quad n = 1, \ldots, M/2. \quad \text{(A.22)}$$

Similar considerations can be made for all the conformal blocks.

It is therefore natural to expand the function $F_{M,N}^a(w; z)$ on the basis of Jack polynomial $J_{\lambda}^{-3}(z)$ where $\lambda$ is a $(2, 2, N)$ admissible partition:

$$F^a(w; z) = \sum_{\lambda} F_{\lambda}^a(w) J_{\lambda}^{-3}(z) \quad \text{(A.23)}$$

$$\lambda \quad (2, 2, N) - \text{admissible}, \quad \lambda_0^0 \leq \lambda_i \leq \Lambda_0^0(M), \quad \text{(A.24)}$$

where $\lambda^0$ and the maximum admissible partition $\Lambda^0(M)$ are given respectively by \eqref{4.18}, where one has to take $h = 1/2$, and by \eqref{4.20}. This shows that, for the Ising case, the choice \eqref{4.18} is a direct consequence of the $(2,2)$-clustering properties. In the above expression we have:

$$\mathcal{H}^{-3}(z) J_{\lambda}^{-3}(z) = \mathcal{E}_{\lambda}^{-3} J_{\lambda}^{-3}(z) \quad \text{(A.25)}$$

with the energies $\mathcal{E}_{\lambda}^{-3}$ given by \eqref{4.7} with $\alpha = -3$.

The $F_{\lambda}^a(w)$ are non-polynomial functions of the variables $w$. Specifying the \eqref{4.7} for the Ising case, one finds that the $P_{\lambda}^4(w)$ are eigenstates of $\mathcal{H}^4$:

$$\mathcal{H}^4(w) F_{\lambda}^4(w) = \mathcal{E}_{\lambda}^4 F_{\lambda}^4(w) \quad \text{(A.26)}$$

with

$$\frac{3}{4} \mathcal{E}_{\lambda}^{-3} + \mathcal{E}_{\lambda}^4 + \frac{5 - M - N}{4} |\lambda| = E(N, M). \quad \text{(A.27)}$$

Note that we have associated the eigenfunctions $P_{\lambda}^4(w)$ to an admissible partition $\lambda$. Until now this is a simply consequence of the expansion \eqref{A.23} Using the expression for $\mathcal{E}_{\lambda}^{-3}$ together with the structure of the $(2,2,N)$-admissible partition $\lambda$, one is lead to the formulas \eqref{4.25} and \eqref{4.22} with $\alpha = 4$ and $h = 1/16$.

The construction shown above generalizes to the case of the $u(1) \otimes W_{A_{k-1}}$ algebras, discussed in section \ref{section}. Indeed, analogously to the case of Ising, one can prove that, in the parafermionic models $W_{A_{k-1}}(k+1, k+r)$ ($k$ and $r$ integers and $k, r \geq 2$), the conformal blocks of $\Phi_{(1, \ldots, |2,1, \ldots, 1)}$ and $\Phi_{(1, \ldots, 1, 1, \ldots, 2)}$ fields \footnote{Note that these fields correspond to the parafermionic currents $\Psi_1$ and $\Psi_{k-1}$ generating the $Z_k$ symmetry} are expressed in terms of Jack polynomials with generalized $(k, r)$–clustering properties \cite{22}. Using the decoupling
equations (6.2) together with the structure of the $(k, r, N)$-admissible Young tableau, one is naturally lead to the formulas (6.12)–(6.13).

**An explicit Ising example: $M = 4$, and $N = 2$**

For sake of clarity, we give here a full explicit example of the above results by considering the conformal block with $M = 4$ spins operators and $N = 2$ energy operators. In this case one has two independent conformal blocks, $F^3(w; z)$, with $a = 1, 2$.

The sum (A.24) runs over the partitions $\lambda : [\emptyset], [1], [2], [1, 1], [2, 1], [2, 2]$. The corresponding Jack polynomials $J_{\lambda}^{-}$ are eigenfunction of $\mathcal{H}^4$ with energy:

\[
\begin{array}{ccccccc}
\text{Function} & J^{-3}_{[\emptyset]} & J^{-3}_{[1]} & J^{-3}_{[2]} & J^{-3}_{[1,1]} & J^{-3}_{[2,1]} & J^{-3}_{[2,2]} \\
\text{Eigenval} & 0 & \frac{2}{3} & \frac{10}{3} & 2 & \frac{14}{3} & 8 \\
|n^a, n^e| & [2, 2] & [2, 1] & [2, 0] & [1, 1] & [1, 0] & [0, 0] \\
\end{array}
\]

while the $F_{\lambda}^{4,a}(w)$, are eigenfunction of $\mathcal{H}^4$ with eigenvalues:

\[
\begin{array}{cccccccc}
\text{Function} & F_{[\frac{1}{4}, \frac{1}{4}, 1, 1]}^{4,a} & F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a} & F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a} & F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a} & F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a} & F_{[\frac{1}{4}, \frac{1}{4}, 0, 0]}^{4,a} \\
\text{Eigenval} & \frac{43}{8} & \frac{41}{8} & \frac{27}{8} & \frac{35}{8} & \frac{21}{8} & \frac{3}{8} \\
|n^a, n^e| & [1, 1, [1, 1] & [1, 1, [1] & [1, 1, [0] & [1, 1] & [1, 0] & [0, 0] \\
\end{array}
\]

Note that the relation (A.27) is satisfied.

We found the explicit form $F_{\lambda}^{4,a}$, $a = 1, 2$, explicitly.

\[
\begin{align*}
F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a}(w) &= \sqrt{w_{13} w_{24} - (-1)^a w_{23} w_{14}} \\
F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a}(w) &= m_{[1]}(w) F_{[\frac{1}{4}, \frac{1}{4}, 0, 0]}^{4,a}(w) \\
F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a}(w) &= \left( -\frac{1}{4} m_{[2]}(w) + \sum_i w_i^3 \partial w_i \right) F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a}(w) \\
F_{[\frac{1}{4}, \frac{1}{4}, 1, 1]}^{4,a}(w) &= \left( \frac{1}{4} m_{[2]}(w) + \frac{1}{2} m_{[1,1]}(w) - \sum_i w_i^3 \partial w_i \right) F_{[\frac{1}{4}, \frac{1}{4}, 1, 0]}^{4,a}(w) \\
F_{[\frac{1}{4}, \frac{1}{4}, 1, 1]}^{4,a}(w) &= m_{[2,1]}(w) F_{[\frac{1}{4}, \frac{1}{4}, 0, 0]}^{4,a}(w) \\
F_{[\frac{1}{4}, \frac{1}{4}, 1, 1]}^{4,a}(w) &= m_{[1,1,1]}(w) F_{[\frac{1}{4}, \frac{1}{4}, 0, 0]}^{4,a}(w)
\end{align*}
\]

where the $m_{\lambda}(w)$ are the symmetric monomial associated to the partition $\lambda$:

\[ m_{\lambda}(\{z_i\}) = S(\prod_i^N z_i^{\lambda_i}). \] (A.28)

Here the $S$ stands for the symmetrization over the $N$ variables.

**B Correspondence between CS Hamiltonians and Integral of motions**

In this appendix we derive the correspondence of section 5.2. This is the central result of this paper. The system of integrals of motions that we obtained is the same as the one introduced in [25].
B.1 Algebraic setting

We consider the algebra \( \text{Vir}(g) \otimes H \) of central charge \( c = 2 - 6(g - 1)^2/g \) generated by

\[
[L_n, L_m] = (n - m)L_{n+m} + \frac{c}{12}n(n^2 - 1)\delta_{n+m,0} \tag{B.1}
\]

\[
[a_n, a_m] = n\delta_{n+m,0} \tag{B.2}
\]

\[
[L_n, a_m] = 0 \tag{B.3}
\]

The Heisenberg algebra contains a Virasoro with \( c = 1 \):

\[
l_n = \frac{1}{2} \sum_{m \in \mathbb{Z}} a_{n-m}a_m \quad n \neq 0 \tag{B.4}
\]

\[
l_0 = \sum_{m>0} a_{-m}a_m + \frac{1}{2}a_0^2 \tag{B.5}
\]

and

\[
[l_n, a_m] = -ma_{n+m} \tag{B.6}
\]

Vertex operators \( V_\beta = :e^{i\beta \varphi(z)}: \) are \( H \) primaries:

\[
a_n V_\beta = 0 \quad n > 0 \tag{B.7}
\]

\[
a_0 V_\beta = \beta V_\beta \tag{B.8}
\]

and as a consequence are also Virasoro primaries (for \( l_n \)) with conformal dimension \( \frac{\beta^2}{2} \).

B.1.1 Ward identities

We are concerned with correlation functions:

\[
F_{a,b} = \langle a|V(z_1)V(z_2)\cdots V(z_N)|b \rangle \tag{B.9}
\]

where \( \langle \beta \rangle \) and \( |\alpha\rangle \) are fields (arbitrary descendants) at \( \infty \) and \( 0 \) respectively. We denote by \( \vec{X}_n \) and \( \rightarrow X_n \) the action of the mode \( X_n \) on these vectors:

\[
\vec{X}_n = \frac{1}{2\pi i} \oint_\infty dz z^n + \frac{\Delta - 1}{2} X(z) \tag{B.10}
\]

\[
\rightarrow X_n = \frac{1}{2\pi i} \oint_0 dz z^n + \frac{\Delta - 1}{2} X(z) \tag{B.11}
\]

where \( \Delta \) is the (integer) dimension of the current \( X(z) \). When acting on \( \langle a|V(z_1)V(z_2)\cdots V(z_N)|b \rangle \), contour deformation yields the generic relation:

\[
\vec{X}_{-n} = \sum_i \sum_{m=1-\Delta}^0 \left( n + \frac{\Delta - 1}{m + \frac{\Delta - 1}{2}} \right) z_i^{n-m} X_m^{(i)} + \rightarrow X_n \tag{B.12}
\]

where \( X_m^{(i)} \) means that the mode \( X_m \) acts on the field \( V(z_i) \) in the correlator. This leads to

\[
\vec{T}_{-n} = \sum_i [(g - 1/2)(n + 1)z_i^n + z_i^{n+1} \partial_i] + \rightarrow T_n \tag{B.13}
\]

including the modified Ward identities:

\[
\vec{T}_{-1} = \sum_i [(2g - 1)z_i + z_i^2 \partial_i] + \vec{T}_1 \tag{B.14}
\]

\[
\vec{T}_0 = \sum_i [(g - 1/2) + z_i \partial_i] + \vec{T}_0 \tag{B.15}
\]

\[
\vec{T}_1 = \sum_i \partial_i + \vec{T}_{-1} \tag{B.16}
\]

28
and for the current $J$:

$$\hat{a}_{-n} = \sqrt{g/2} \sum_i z_i^n + \hat{a}_{a_n} \quad (B.17)$$

### B.1.2 Contour deformations

Using standard contour deformation techniques, we obtain for $n \in \mathbb{Z}$

$$a_{-n}^{(i)} = -\sum_{j(\neq i)} \frac{\sqrt{g/2}}{(z_i - z_j)^n} - (-1)^n \sum_{m \geq 0} (m + n - 1) z_i^{-m-n} a_m + \sum_{m \geq n} (m - 1) z_i^{m-n} a_m \quad (B.18)$$

in particular

$$a_{-1}^{(i)} = \sum_{j(\neq i)} \frac{\sqrt{g/2}}{(z_i - z_j)^2} + \sum_{m \geq 1} z_i^{-m-1} a_m + \sum_{m \geq 1} z_i^{-m} a_m \quad (B.19)$$

$$a_{-2}^{(i)} = -\sum_{j(\neq i)} \frac{\sqrt{g/2}}{(z_i - z_j)^2} - \sum_{m \geq 0} (m + 1) z_i^{-m-2} a_m + \sum_{m \geq 2} (m - 1) z_i^{m-2} a_m \quad (B.20)$$

For the Virasoro mode $T_{-2}$:

$$T_{-2}^{(i)} = \sum_{j(\neq i)} \left[ \frac{g - 1/2}{(z_i - z_j)^2} + \frac{\partial_j}{(z_i - z_j)} \right] + \sum_{m \geq -1} \frac{T_m}{z_i^{m+2}} + \sum_{m \geq 2} z_i^{m-2} T_m \quad (B.22)$$

### B.2 Derivation of the correspondence

#### B.2.1 Correspondence at level 1

The first order CS Hamiltonian is the generator of dilatations $H_1 = \sum_i (z_i \partial_i)$. Scale invariance dictates

$$\sum_i (\Delta + z_i \partial_i) F_{a,b} = \left( \tilde{T}_0 - T_0 \right) F_{a,b} \quad (B.23)$$

and we get

$$I_2^\pm = T_0 = L_0 + \sum_{m \geq 0} a_m a_{-m} + \frac{1}{2} a_0^2 \quad (B.24)$$

which is nothing but the zero mode of the total stress energy tensor in $Vir(g) \otimes H$. Since $a_0$ commutes with the whole algebra, we are free to choose

$$I_2^\pm = L_0 + \sum_{m \geq 0} a_m a_{-m} \quad (B.25)$$

#### B.2.2 Correspondence at level 2

The correspondence between the order 2 CS Hamiltonian

$$H_2^g = \sum_{i=1}^N \left( z_i \frac{\partial}{\partial z_i} \right)^2 + g(1 - g) \sum_{i \neq j} \frac{z_i z_j}{z_{ij}^2} \quad (B.26)$$

and the operator $I_3$ comes from the degeneracy at level 2 in the module of $V = \Phi(1/2) : e^{i\sqrt{2} \varphi} :$

$$(L_{-1} - g L_{-2}) V = 0 \quad (B.27)$$
An important point is that $L_{-1}$ is no longer a simple derivative in the extended algebra $Vir(g) \otimes H$, as we must now deal with the total Virasoro algebra generated by $T_n = L_n + l_n$. This degeneracy becomes:

$$\left( T_{-1}^2 - gT_{-2} + (g-1)\sqrt{g/2}a_{-2} + ga_{-1}^2 - 2\sqrt{g/2}a_{-1}T_{-1} \right) V = 0 \quad (B.28)$$

This yields the following relation:

$$\sum_{i=1}^{N} z_i^2 \left( \partial_i^2 - gT_{-2}^{(i)} + (g-1)\sqrt{g/2}a_{-2}^{(i)} + g\left(a_{-1}^{(i)}\right)^2 - 2\sqrt{g/2}a_{-1}^{(i)}\partial_i \right) F_{a,b} = 0 \quad (B.29)$$

Using the contour deformations of the previous section all these terms can be handled. For instance

$$\sum_{i=1}^{N} z_i^2 T_{-2}^{(i)} (\beta|V(z_1)V(z_2) \cdots V(z_N)|\alpha) = \left[ \sum_{m \geq 0} p_{-m} \tilde{T}_m + \sum_{m \geq 1} p_m \tilde{T}_m \right] \langle \beta|V(z_1)V(z_2) \cdots V(z_N)|\alpha \rangle \quad (B.30)$$

$$+ \left[ (g-1/2) \sum_{i \neq j} \frac{z_i z_j}{z_{ij}} - \frac{1}{2} \sum_{i \neq j} \frac{z_i z_j}{z_{ij}} (\partial_i - \partial_j) - \sum_{i=1}^{N} z_i \partial_i \right] \langle \beta|V(z_1)V(z_2) \cdots V(z_N)|\alpha \rangle \quad (B.31)$$

We obtained the following relation for $F_{a,b} = \langle a|V(z_1)V(z_2) \cdots V(z_N)|b \rangle$

$$H_3^a F_{a,b} = \left[ I_3^{-}(g) + I_3^{+}(g) + 4(g-1) \sum_{m \geq 1} m \tilde{a}_m a_m \right] F_{a,b} \quad (B.32)$$

with

$$I_3^{(\pm)}(g) = 2(1-g) \sum_{m \geq 1} m a_{-m} a_m \pm \sqrt{2g} \sum_{m \geq 1} (a_{-m}L_m + L_{-m}a_m) \pm \frac{g}{2} \left( \sum_{m,k \geq 1} a_{-m-k} a_m a_k + a_{-m-k} a_m a_k \right) \quad (B.33)$$

The extra term $\sum_{m \geq 1} m \tilde{a}_m a_m \tilde{a}_m$ vanishes identically whenever $a$ or $b$ is primary, and $\mathcal{E}$ is simply a constant:

$$\mathcal{E} F_{a,b} = \left[ g(N-1) + (1-g) + 2\sqrt{g/2}a_0 \right] \sum_{i} z_i \partial_i \right] F_{a,b}$$

$$+ \left[ gN \tilde{T}_0 + (g-1)N \sqrt{g/2}a_0 - g \left( g \left( N \frac{N}{3} \right) + (1-g) \left( N \frac{N}{2} \right) + 2 \sqrt{g/2}a_0 \left( N \frac{N}{2} \right) + N \tilde{a}^2_0 \right) \right] F_{a,b} \quad (B.34)$$

### B.2.3 Correspondence at level 3

It is quite natural to expect that a relation involving the order 3 CS Hamiltonian

$$H_3^a = \sum_{i=1}^{N} \left( z_i \frac{\partial}{\partial z_i} \right)^3 + \frac{3}{2} g^2 (1-g) \sum_{i \neq j} \frac{z_i z_j}{z_{ij}^2} (z_i \partial_i - z_j \partial_j) \quad (B.35)$$

can be obtained from a degeneracy at level 3 of $V = \Phi_{(1|2)} : e^{i\sqrt{2}\varphi} :$. However there are two such null states:

- $L_{-1} \left( L_{-1}^2 - gL_{-2} \right) V = 0$
- $a_{-1} \left( L_{-1}^2 - gL_{-2} \right) V = 0$

and taking a generic linear combination of them will not work: the corresponding relation will not separate into a differential operator on one side and an operator acting in the conformal Hilbert space on the other side. It turns out that demanding this separability amounts to consider the degeneracy:

$$\left( L_{-1} + 3\sqrt{g/2}a_{-1} \right) \left( L_{-1}^2 - gL_{-2} \right) V = 0 \quad (B.36)$$
\[ T_{-1}^3 - g T_{-1} T_{-2} + (g - 3) \sqrt{\frac{g}{2}} a_{-2} T_{-1} - g \sqrt{2} a_{-1} T_{-2} - \sqrt{2} g a_{-1} T_{-2} + (g - 1) \sqrt{2} g a_{-3} + g (g + 1) a_{-1} a_{-2} + g \sqrt{2} g a_{-1} \]

Using the same techniques as for the level 2 degeneracy we obtained the expression

\[ T^+_4 (g) = -g \sum_{m > 0} L_m L_m \]

\[ -3 g \sum_{m,p > 0} (2 L_p - m a_{p+m} + 2 a_{m-p} L_p + a_{m-p} L_{p+m} + L_{m-p} a_m a_p) \]

\[ \pm 3 \sqrt{2} g (g - 1) \sum_{m > 0} m (a_m L_m + L_m a_m) \pm 3 \sqrt{2} g (g - 1) \sum_{m,p > 0} m (a_m a_{p+m} + a_{m-p} a_m a_p) \]

\[ -\frac{1}{2} g L_0^2 - 3 g L_0 \sum_{m > 0} a_m a_m + \sum_{m \geq 1} \left[ \frac{1}{2} (9 g - 5 - 5 g^2) m^2 - \frac{1}{2} (g - 1)^2 \right] a_m a_m \]

\[ -\frac{g}{8} \sum_{m_i + m_2 + m_3 + m_4 = 0} : a_{m_1} a_{m_2} a_{m_3} a_{m_4} : \]

\[ (B.37) \]

\[ (B.38) \]

### C Integral-differential representation of non-polynomial Calogero Sutherland eigenfunctions

We have shown that the correlation functions of CFT minimal models admit a particular separation of variables, see \[4.13\]. This result points out the existence of a new families of eigenfunctions of \[2.12\], the \[F_0^{\alpha,\gamma}(z)\].

Each of these solutions is associated to a set \(\lambda\) which is related to the two partitions \(n^e\) and \(n^o\), \(\lambda \rightarrow [n^e, n^o]\) \[4.21\]. The associated eigenvalue have been given in \[4.25\].

Here we want to show that:

- the function \(F_0^{\alpha,\gamma}(z)\), see \[4.13\] and \[4.20\], can be expressed in terms of contour integrals by using standard Coulomb gas methods.

- the "excited states" \(F^{\alpha,\gamma}_{\lambda}(z)\) can be written in terms of symmetric differential operators acting on \(F_0^{\alpha,\gamma}(z)\).

#### Coulomb gas representation of \(F_0^{\alpha,\gamma}(z)\)

Consider for instance the eigenfunction \(F_0^{\alpha,\gamma}(z)\), \(\alpha^{-1} = 1 - g\), constructed from the conformal block of \(\Phi_{(1|2)}\) primary fields:

\[ F_0^{\alpha,\gamma}(z) = \langle \Phi_{(1|2)}(z_1) \cdots \Phi_{(1|2)}(z_N) \rangle_b \prod_{1 \leq i < j \leq N} z_{ij}^{2h} \]

\[ (C.1) \]

where the dimension \(h\) is given in \[4.3\]. Note that, with respect to the definition \[5.38\] given in section \[5.2\], the function \(F_0^{\alpha,\gamma}(z)\) corresponds to:

\[ F_0^{\alpha,\gamma}(z) = \langle e^{iN \sqrt{g/2} \phi} \otimes |V(z_1) V(z_2) \cdots V(z_N)| \otimes |I\rangle_b \prod_{1 \leq i < j \leq N} z_{ij}^{g-1} \]

\[ (C.2) \]

In the above equation, the factor \(\prod_{1 \leq i < j} z_{ij}^{g-1}\) can also be understood by remembering the fact that in section \[5.2\] we worked in the gauge of the Hamiltonian \[2.9\] with \(\gamma = 0\) while here we are considering the eigenfunctions of \[2.9\] with \(\gamma = 1 - g\).

31
In the Coulomb gas representation, the operators $Φ_{1|2}(z_1)$ are represented by vertex operator, see [5.35]. A crucial role is played by the screening operators:

$$V_\pm(z) = e^{iα_±φ(z)}$$  \hspace{1cm} (C.3)

which are primary operator of conformal dimension $h_± = 1$. Suppose one in interested in the computation of a general conformal block

$$\langle \prod_i^n \Phi_{α_i}(z_i) \rangle.$$  \hspace{1cm} (C.4)

The above conformal block is obtained by considering the following free boson correlation function

$$Φ(z, x, y) = \prod_i e^{iα_0φ(z_i)} \prod_j V_+(x_j) \prod_j V_-(y_j) =$$

$$= \prod_{1≤i<j≤N} z_{ij}^{2α_+} \prod_{1≤i≤N} \prod_{1≤j≤N} (z_i - x_j)^{2α_+} \prod_{1≤i≤N} \prod_{1≤j≤m} (z_i - y_j)^{2α_-},$$  \hspace{1cm} (C.6)

$$= \prod_{1≤i<j≤N} (x_i - x_j)^{2α_+} \prod_{1≤i≤N} \prod_{1≤j≤m} (x_i - y_j)^{-2},$$  \hspace{1cm} (C.7)

where the number of screenings $n$ and $m$ is chosen in order to satisfy the charge neutrality condition:

$$∑ i α_i + nα_+ + mα_- = 2α_0,$$  \hspace{1cm} (C.8)

with $α_0$ given in [5.35]. The conformal block $⟨ Π_i^n \Phi_{α_i}(z_i) ⟩$ is given by integrating the $Φ(z, x, y)$ over the positions of the $n + m$ screenings. The contours of integration have to be closed in the Riemann surface on which $Φ(z, x, y)$ is defined. One has:

$$⟨ \prod_i^n \Phi_{α_i}(z_i) ⟩ ≈ \prod_i^n \prod_j^m \int_{C_i} dx \int_{S_j} dy \ Φ(z, x, y)$$  \hspace{1cm} (C.9)

By setting $Φ_{12}(z_i) = e^{iα_{12}φ(z_i)}$, for $i = 1, 2, \ldots, N - 1$ and $Φ_{12}(z_N) = e^{i(2α_0 - α_{12})φ(z_N)}$, the charge neutrality condition [C.8] associated to the conformal block in [C.1] is satisfied with $n = (N - 2)/2$. We have then:

$$F^{1/(1-g),b}_{\lambda_0}(z) \propto \prod_{1≤i<j≤N} z_{ij}^{α_0_+/2} \prod_{1≤i≤(N-2)/2} \int_{C_i} dx \prod_{1≤i≤N} \prod_{1≤j≤(N-2)/2} (z_i - x_j)^{-α_0_-} \prod_{1≤i<j≤(N-2)/2} (x_i - x_j)^{2α_0_+},$$  \hspace{1cm} (C.10)

Note that one could directly prove that a function of the above form defines, for appropriate closed integration contours $C_i$, a solution of [2.12] (see for instance [52, 53]).

The different conformal blocks giving $F^{1/(1-g),b}_{\lambda_0}(z)$ (we recall that in our notation the different conformal blocks are indexed by the integer $b$) correspond to the different independent ways of choosing closed contours $C_i$. One can easily show [20] that each choice is associated to certain boundary conditions. As an example, we can let the contour $C_i$ encircling the points $z_{2i-1}$ and $z_{2i}$ (with figure-8 contours in order to take into account the branch cuts). The contours can then be shrinked to give the following integral expression:

$$F^{1/(1-g),1}_{\lambda_0}(z) \propto \prod_{1≤i<j≤N} z_{ij}^{α_0_+/2} \prod_{1≤i≤(N-2)/2} \int_{z_{2i-1}}^{z_{2i}} dx_i \prod_{1≤i≤N} \prod_{1≤j≤(N-2)/2} (z_i - x_j)^{-α_0_-} \prod_{1≤i<j≤(N-2)/2} (x_i - x_j)^{2α_0_+}.$$  \hspace{1cm} (C.11)

The $F^{1/(1-g),1}_{\lambda_0}(z)$ corresponds to the conformal block where the fields $Φ(z_{2i-1})$ and $Φ(z_{2i})$ fuse into the identity channel: the function $F^{1/(1-g),1}_{\lambda_0}(z)$ behaves has $F^{1/(1-g),1}_{\lambda_0}(z) \sim (z_{2i-1} - z_{2i})^0$ for $z_{2i} \to z_{2i-1}$.

For general central charge, the number of conformal block is the Catalan of $N/2$, $C_{N/2}$, i.e. $b = 1, \ldots, C_{N/2}$. Naturally for values of central charge associated to rational CFTs, one has to take into account the truncations in the operator algebra. This is the case for instance for the $c = 1/2$ theory, which we have discussed in detail in section [A.2].

32
It is interesting to mention that in [48] it was shown how to derive the (anharmonic ratio-) expansion of a four-point conformal block from its Coulomb gas representation.

Formal solutions for the excited states.

It is interesting to recall a known result for the Jack eigenfunctions $J^\lambda_0(z)$. One defines [49] a class of operators $D_\lambda$ which are particular symmetric combination of differential operators acting on a function $f(z)$, $D_\lambda[f(z)]$, and which are associated to a partition $\lambda$. The Jack polynomials can be obtained acting with this class of symmetric operators on the ground state wavefunction $J^\lambda_0(z)$, with $\lambda^0 = [\emptyset]$, which is the trivial constant function, $J^\lambda_0(z) = 1$:

$$J^\lambda_0(z) = D_\lambda^0[J^\lambda_0(\emptyset)(z)] = D_\lambda^0[1] \quad (C.12)$$

In an analogous way, we can show that the non-polynomial solution $F^{1/(1-g),b}_\lambda(z)$ can be obtained by acting with a symmetric differential operator $O_\lambda[f(z)]$ on the reference state $F^{1/(1-g),b}_\lambda(\emptyset)(z)$:

$$F^{1/(1-g),b}_\lambda(z) = O_\lambda[F^{1/(1-g),b}_\lambda(\emptyset)(z)] \quad (C.13)$$

We have seen in section [5.2] that an eigenfunctions of $H^g_\lambda = H^{g,0}$, see [2.9], can take the form [5.49]. We consider here the function $F^{(g,\tau)}_\lambda(z)$, see [5.49], in which the primary $\{P > \}$ and the state $\mid P^+(\lambda) \rangle$ appearing in [5.49] are respectively the trivial state $I \otimes I$ and a descendant state of $e^{iN\sqrt{g/2} \phi} \otimes I$:

$$F^{(g,\tau)}_\lambda(z) = \langle P^+(\lambda)|V(z_1)V(z_2)\cdots V(z_N)|I \otimes I \rangle_b \quad (C.14)$$

We recall that $\mid P^+(\lambda) \rangle >$ is an eigenstate of $I^{(\pm)}_{n+1}(\lambda)$ and it is labelled by the two partitions $[n^c, n^o]$, $P^+(\lambda) \rightarrow P^+_\lambda([n^c, n^o])$, see sections [5.3]-[5.4]. Again, if we are interested in the eigenfunctions of the CS Hamiltonian $H^{g,1-g}$ we have simply:

$$F^{1/(1-g),b}_\lambda(z) = F^{(g,\tau)}_\lambda(z) \prod_{1 \leq i < j \leq N} \frac{z_i^{g-1}}{z_j^{g-1}} \quad (C.15)$$

In order to simplify the notation, we indicate $\mid I \otimes I \rangle \equiv \{0\}$, $e^{iN\sqrt{g/2} \phi} \otimes I \equiv \{N\}$ and $\mid P^+_\lambda([n^c, n^o]) \rangle \equiv \{[n^c, n^o]\}$.

One can then show the validity of [C.13] by the following procedure:

- Find the basis $[[n^c, n^o]]$ which diagonalizes the operator $I^+_3(\lambda)$ [5.54]. Each state $[[n^c, n^o]]$ is then found as a given combination $O_\lambda(\{L-n\}, \{a-n\})$ of Virasoro modes $L-n$ and of $u(1)$ current modes $a_n$ acting on $e^{iN\sqrt{g/2} \phi} \otimes I$ state:

- From the relations [B.12], one can write the action of the algebra modes in terms of differential operator acting on the correlation function $F^{(g,\tau)}_{\{n^c, n^o\}}(z) = \langle N|V(z_1)V(z_2)\cdots V(z_N)|\emptyset\rangle_b$:

$$F^{(g,\tau)}_{\{n^c, n^o\}}(z) = O'_{\{n^c, n^o\}}[F^{(g,\tau)}_{\{n^c, n^o\}}(z)] \quad (C.16)$$

where $O'_{\{n^c, n^o\}}[f(z)]$ will be particular symmetric combination of differential operators, associated to the descendant $\{\lambda\}$, acting on a function $f(z)$.

- The differential operator defined in [C.13] is then

$$O_{\{n^c, n^o\}} = \left( \prod_{1 \leq i < j \leq N} z_i^{1-g} \right) O'_{\{n^c, n^o\}} \left( \prod_{1 \leq i < j \leq N} \frac{z_i^{g-1}}{z_j^{g-1}} \right) \quad (C.17)$$

We illustrate the above procedure by considering the basis $[[n^c, n^o]]$ which diagonalizes $I^+_3$, see [5.43], at the first and at the second level in the module $|N\rangle$.

Descendants level one

At the first level there is only one descendant.

$$\{1\}, \{\emptyset\} \rightarrow O'_{\{1\}, \{\emptyset\}}(\{L-n\}, \{a-n\})\{\emptyset\} = a-1|N\rangle \quad (C.18)$$
Using (B.17) one has:

$$\langle [1], [0] | V(z_1)V(z_2) \cdots V(z_N) | 0 \rangle_b = \left( \sum_i z_i \right) \langle N | V(z_1)V(z_2) \cdots V(z_N) | 0 \rangle .$$  \hspace{1cm} (C.19)

This means that the operator $O'_{[1],[0]}[f(z)]$ simply multiplies the function $f(z)$ by the monomial $m_{[1]}(z)$:

$$O'_{[1],[0]}[f(z)] = \sum_i z_i f(z) = m_{[1]}(z)f(z).$$  \hspace{1cm} (C.20)

**Descendants level two**

We have three descendants at level two. In the basis $a_{-2}|0\rangle$ and $\sqrt{2}g a_{-1}|0\rangle$ and $\sqrt{2}g L_{-2}|0\rangle$, the operator $I_3^+(g)$, reads

$$I_3^+(g) = \begin{pmatrix}
8(1-g) & 2g & g c(g) \\
1 & 4(1-g) & 0 \\
2 & 0 & 0
\end{pmatrix}$$

The correspondent eigenvectors are:

$$|2],[0] > = \left[ 3 - 2g \right] a_{-2} + \left[ \frac{3}{2} - g \right] \sqrt{2} g a_{-1} + \sqrt{2} g L_{-2} |N >$$

$$|[1,1], [0] > = \left[ 2 - 3g \right] a_{-2} + \left[ \frac{3}{2} - g \right] \sqrt{2} g a_{-1} + \sqrt{2} g L_{-2} |N >$$ \hspace{1cm} (C.21)

$$|[1], [1] > = \left[ 1 - g \right] a_{-2} - \frac{1}{2} \sqrt{2} g a_{-1} + \sqrt{2} g L_{-2} |N >$$

with eigenvalues $6 - 4g$, $4 - 6g$ and $2 - 2g$ respectively. Note that for $g = 1$ this is the same basis as in Section 5.3 where we used instead the bosonic representation of the Virasoro algebra. Taking into account:

$$L_{-2}|N > = (T_{-2} - a_{-2} a_0 - \frac{1}{2} a_{-1}^2) |N >$$  \hspace{1cm} (C.22)

it is straightforward to use the relations (B.13) and (B.17) to associate to each descendant a symmetric differential operator acting on the function $F_{([0],[0])}(z)$. By remplacing:

$$L_{-2}|N > \rightarrow \left[ \frac{11 - 2N}{4} g - \frac{1}{2} \right] m_{[2]}(z) - \frac{g}{2} m_{[1,1]} + \sum_{1 \leq i \leq N} z_i \partial_i \right] F_{([0],[0])}(z)$$  \hspace{1cm} (C.23)

$$a_{-2}|N > \rightarrow \left[ g \frac{m_{[2]}(z)}{2} \right] F_{([0],[0])}(z)$$  \hspace{1cm} (C.24)

$$a_{-1}^2|N > \rightarrow \left[ g \frac{m_{[2]}(z) + gm_{[1,1]}(z)}{2} \right] F_{([0],[0])}(z)$$  \hspace{1cm} (C.25)

the expressions for $O'_{[n_*],[n_*]}[f(z)]$ and for $O_{[n_*],[n_*]}[f(z)]$ are easily found. In appendix B, where we considered the case with $N = 4$ and $g = 4/3$, the explicit expression for $O_{[1],[1]}$ and $O_{[1,1],[0]}$ were shown.
