MICROLOCAL LIFTS AND QUANTUM UNIQUE ERGODICITY
ON GL_2(\mathbb{Q}_p)

PAUL D. NELSON

Abstract. We prove that arithmetic quantum unique ergodicity holds on compact arithmetic quotients of GL_2(\mathbb{Q}_p) for automorphic forms belonging to the principal series. We interpret this conclusion in terms of the equidistribution of eigenfunctions on covers of a fixed regular graph or along nested sequences of regular graphs.

Our results are the first of their kind on any p-adic arithmetic quotient. They may be understood as analogues of Lindenstrauss’s theorem on the equidistribution of Maass forms on a compact arithmetic surface. The new ingredients here include the introduction of a representation-theoretic notion of “p-adic microlocal lifts” with favorable properties, such as diagonal invariance of limit measures; the proof of positive entropy of limit measures in a p-adic aspect, following the method of Bourgain–Lindenstrauss; and some analysis of local Rankin–Selberg integrals involving the microlocal lifts introduced here as well as classical newvectors. An important input is a measure-classification result of Einsiedler–Lindenstrauss.

1. Introduction

1.1. Overview. Let p be a prime number. This article is concerned with the limiting behavior of eigenfunctions on compact arithmetic quotients of the group \( G := \text{GL}_2(\mathbb{Q}_p) \). A rich class of such quotients is parametrized by the definite quaternion algebras \( B \) over \( \mathbb{Q} \) that split at \( p \). A maximal order \( R \) in such an algebra and an embedding \( B \hookrightarrow M_2(\mathbb{Q}_p) \) give rise to a discrete cocompact subgroup \( \Gamma := R[1/p]^\times \) of \( G \). Fix one such \( \Gamma \). The corresponding arithmetic quotient \( X := \Gamma \backslash G \) is then compact; in interpreting this, it may help to note that the center of \( \Gamma \) is the discrete cocompact subgroup \( \mathbb{Z}[1/p]^\times \) of \( \mathbb{Q}_p^\times \).

2010 Mathematics Subject Classification. Primary 58J51; Secondary 22E50, 37A45.
The space $X$ is a $p$-adic analogue of the cotangent bundle of an arithmetic hyperbolic surface, such as the modular surface $\text{SL}_2(\mathbb{Z})\backslash \mathbb{H}$. It comes with commuting families of Hecke correspondences $T_\ell$ indexed by the primes $\ell \neq p$ (see §3.1). To zeroth approximation, the space $X$ is modelled by its minimal quotient $Y := X/K = \Gamma \backslash G/K$ by the maximal compact subgroup $K := \text{GL}_2(\mathbb{Z}_p)$ of $G$. Then $Y$ may be safely regarded as an undirected $(p+1)$-regular finite multigraph (see §1.1). For simplicity, it will be convenient to assume that

$$(\text{the torsion subgroup of } \Gamma) = \{\pm 1\}.\quad (1)$$

Such graphs and their eigenfunctions appear naturally in several contexts, and have been extensively studied since the pioneering work of Brandt and Eichler [3, 10]; they specialize to the $p$-isogeny graphs of elliptic curves in finite characteristic [12, §2], provide an important tool for constructing spaces of modular forms [28], and their remarkable expansion properties have been studied and applied in computer science following [21].

To study the space $X$ at a finer resolution than that of its minimal quotient $Y$, we introduce for each pair of integers $m, m'$ the notation $m..m' := \{m, m+1, \ldots, m'\}$ and set

$$Y_{m..m'} := \left\{ \text{non-backtracking paths } x = (x_m \to x_{m+1} \to \cdots \to x_{m'}) \right\}, \quad (2)$$

We will recall in Definition 10 the standard group-theoretic realization of $Y_{m..m'}$ as a quotient of $X$. We may and shall identify $Y_{0..0}$ with $Y$. For $m..m' \supseteq n..n'$, we define compatible surjections $Y_{m..m'} \to Y_{n..n'}$ by forgetting part of the path. For example, if $N \geq 0$, then the map $Y_{-N..N} \to Y_{0..0} = Y$ sends a path $x$ as in (2) to its central vertex $x_0$. We define $L^2(Y_{m..m'})$ with respect to the normalized counting measure, so that the maps $Y_{m..m'} \to Y_{n..n'}$ are measure-preserving.

We wish to study the asymptotic behavior of "eigenfunctions" in $L^2(Y_{m..m'})$ as $|m - m'| \to \infty$. From the arithmetic perspective, there is a distinguished collection of such eigenfunctions, whose definition is analogous to that of the set of normalized classical holomorphic newforms of some given weight and level:

**Definition 1 (Newvectors).** Let by $F_{m..m'} \subseteq L^2(Y_{m..m'})$ be an orthonormal basis for the space of functions $\varphi : Y_{m..m'} \to \mathbb{C}$ satisfying the following conditions:

1The images were produced using the “Graph” and “BrandtModule” functions in SAGE [38].
(1) the pullback of $\varphi$ to $X = \Gamma \backslash G$ generates an irreducible representation of $G = \text{GL}_2(\mathbb{Q}_p)$ under the right translation action.

(2) $\varphi$ is an eigenfunction of the Hecke operator $T_\ell$ (see §3.1) for all primes $\ell \neq p$.

(3) $\varphi$ is orthogonal to pullbacks from $Y_{n..n'}$ whenever $n..n' \subset m..m'$.

It is known that $|F_m..m'| \approx |Y_m..m'| \approx p^{|m-m'|}$ for $|m-m'|$ sufficiently large.

To simplify the exposition of §1.1, we focus on the symmetric intervals $-N..N$.

Fix $n \in \mathbb{Z}_{\geq 0}$. Let $N \geq n$ be an integral parameter tending off to $\infty$. Denote by $\text{pr} : Y_{-N..N} \twoheadrightarrow Y_{-n..n}$ the natural surjection. For $\varphi \in F_{-N..N}$, we may define a probability measure $\mu_\varphi$ on $Y_{-n..n}$ by setting

$$\mu_\varphi(E) := \frac{1}{|Y_{-N..N}|} \sum_{x \in Y_{-N..N} : \text{pr}(x) \in E} |\varphi|^2(x).$$

For example, in the instructive special case $n = 0$, the measures $\mu_\varphi$ live on the base graph $Y_{0..0} = Y$ and assign to subsets $E \subseteq Y$ the number

$$\mu_\varphi(E) = \frac{1}{|Y_{-N..N}|} \sum_{x = (x_{-N} \rightarrow \cdots \rightarrow x_{0}) \in Y_{-N..N} : x_{0} \in E} |\varphi|^2(x),$$

which quantifies how much mass $\varphi : Y_{-N..N} \to \mathbb{C}$ assigns to paths whose central vertex lies in $E$.

**Question 2.** Fix $n \in \mathbb{Z}_{\geq 0}$. Let $N \geq n$ traverse a sequence of positive integers tending to $\infty$. For each $N$, choose an element $\varphi_n \in F_{-N..N}$. What are the possible limits of the sequence of measures $\mu_{\varphi_n}$ on the space $Y_{-n..n}$?

The following conjecture has not appeared explicitly in the literature, but may be regarded nowadays as a standard analogue of the arithmetic quantum unique ergodicity conjecture of Rudnick–Sarnak [31] (cf. [32, 26] and references).

**Conjecture 3.** In the context of Question 2, the uniform measure on $Y_{-n..n}$ is the only possible weak limit. In other words, for any sequence $\varphi_n \in F_{-N..N}$ and any $E \subseteq Y_{-n..n}$,

$$\lim_{N \to \infty} \mu_{\varphi_n}(E) = \frac{|E|}{|Y_{-n..n}|}.$$  

Conjecture 3 predicts that for any sequence $\varphi_n \in F_{-N..N}$, the corresponding sequence of $L^2$-masses $\mu_{\varphi_n}$ equidistributes under pushforward to any fixed space $Y_{-n..n}$. One can formulate this conclusion more concisely in terms of equidistribution on the compact space $\lim \leftarrow Y_{-n..n}$ of infinite bidirectional non-backtracking paths, or equivalently, on the space $X = \Gamma \backslash G$.

By explicating the triple product formula [16], one can show that Conjecture 3 follows from an open case of the subconvexity conjecture, which in turn follows from GRH; the latter can be shown to imply more precisely that

$$\mu_{\varphi_n}(E) = \frac{|E|}{|Y_{-n..n}|} + O(p^{-(1+o(1))N/2})$$

for fixed $n$. There are nowadays well-developed techniques (see for instance [25, §1.4]) to show that
• the prediction (3) holds for \( \varphi_N \) outside a hypothetical exceptional subset of density \( o(1) \), that
• if (3) is true, it is essentially optimal, and that
• Conjecture 3 holds for \( \varphi_N \) outside a hypothetical exceptional subset of extremely small density \( |\mathcal{F}_{-N,N}|^{-1/2+o(1)} = o(1) \),

but the problem of eliminating such exceptions entirely (in the present setting and related ones) has proved subtle.

For context, we recall some instances in which the difficulty indicated above has been overcome; notation and terminology should be clear by analogy.

**Theorem 4** (Lindenstrauss [20]). Let \( \Delta \backslash \mathbb{H} \) be a compact hyperbolic surface attached to an order in a non-split indefinite quaternion algebra. Let \( \varphi \) traverse a sequence of \( L^2 \)-normalized Hecke–Laplace eigenfunctions on \( \Delta \backslash \mathbb{H} \) with Laplace eigenvalue tending to \( \infty \). Then the \( L^2 \)-masses \( \mu_\varphi \) equidistribute.

**Theorem 5** (N, N–Pitale–Saha, Hu [23, 26, 14]). Fix a natural number \( q_0 \). Let \( q \) traverse a sequence of natural numbers tending to \( \infty \). Let \( \varphi \) be an \( L^2 \)-normalized holomorphic Hecke newform on the standard congruence subgroup \( \Gamma_0(q) \) of \( SL_2(\mathbb{Z}) \). Then the pushforward to \( \Gamma_0(q_0) \backslash \mathbb{H} \) of the \( L^2 \)-mass of \( \varphi \) equidistributes.

We may of course specialize Theorem 5 to powers of a fixed prime:

**Theorem 6** (N, N–Pitale–Saha, Hu [23, 26, 14]). Fix a prime \( p \) and a nonnegative integer \( n_0 \). Let \( n \) traverse a sequence of natural numbers tending to \( \infty \). Let \( \varphi \) be an \( L^2 \)-normalized holomorphic Hecke newform on \( \Gamma_0(p^n) \). Then the pushforward to \( \Gamma_0(p_0^n) \backslash \mathbb{H} \) of the \( L^2 \)-mass of \( \varphi \) equidistributes.

Conjecture 3 is in the spirit of Theorem 6, save a crucial distinction to be discussed in due course (see Remark 19). Unfortunately, the method underlying the proof of Theorem 6, due to Holowinsky–Soundararajan [13], is fundamentally inapplicable to Conjecture 3 due to its reliance on parabolic Fourier expansions, which are unavailable on the compact quotient \( X \). We will instead develop here a method more closely aligned with that underlying the proof of Theorem 4.

To describe our result, we must recall that the elements of \( \mathcal{F}_{-N,N} \) may be partitioned according to the isomorphism class of the representation of \( G = GL_2(\mathbb{Q}_p) \) that they generate. For \( N \geq 1 \), any such representation is either

1. a (ramified) principal series representation (see §5.3), or
2. a (supercuspidal) discrete series representation.

A (computable) positive proportion of elements of \( \mathcal{F}_{-N,N} \) belongs to either category. The dichotomy here is analogous to that on \( SL_2(\mathbb{Z}) \backslash SL_2(\mathbb{R}) \) between Maass forms (principal series) and holomorphic forms (discrete series).

**Theorem 7** (Main result). The conclusion of Conjecture 3 holds if \( \varphi_N \) belongs to the principal series.

Theorem 7 represents the first genuine instance of arithmetic quantum unique ergodicity in the level aspect on a compact arithmetic quotient and also the first on any \( p \)-adic arithmetic quotient. It says that for a sequence \( \varphi_N \in \mathcal{F}_{-N,N} \) belonging to the principal series, the corresponding \( L^2 \)-masses equidistribute under pushforward to any fixed space \( Y_{-n..n} \).

**Remark 8.** Our result might be described concisely as arithmetic quantum unique ergodicity on the path space over the fixed regular graph \((Y, T_p)\) and as contributing
to the growing literature concerning quantum chaos on regular graphs (see [4, 5, 1] and references). Alternatively, one could fix an auxiliary split prime \( \ell \neq p \), regard \((\mathbf{Y}_{-N}, T_{\ell})\) as traversing an inverse system of \((\ell + 1)\)-regular graphs, and interpret Theorem 17 as a form of arithmetic quantum unique ergodicity for such a sequence of graphs.

**Remark 9.** Assuming the multiplicity hypothesis that an element \( \varphi \in \mathcal{F}_{-N,N} \) generating an irreducible principal series representation of \( G \) is automatically an eigenfunction of the \( T_{\ell} \) for \( \ell \neq p \) (which is inspired by analogy from the conjectural simplicity of the spectrum of the Laplacian on \( SL_2(\mathbb{Z}) \)), Theorem 17 may be understood as telling us something new about individual finite graphs \((\mathbf{Y}, T_{p})\), such as those pictured above, together with their realization as \( \Gamma \backslash G/K \).

As indicated already, the proof of Theorem 7 is patterned on that of Theorem 4. An important ingredient in the proof of Theorem 4 is the existence of a measure \( \mu \) on \( \Delta \backslash SL_2(\mathbb{R}) \), called a *microlocal lift*, with the properties:

- \( \mu \) lifts the measure \( \lim_{j \to \infty} \mu_{\varphi_j} \) on \( \Delta \backslash \mathbb{H} \).
- \( \mu \) is invariant under right translation by the diagonal subgroup of \( SL_2(\mathbb{R}) \).
- \( (\mu_{\varphi_j}) \mapsto \mu \) is compatible with the Hecke operators (see [36, Thm 1.6] for details); this third property is that which is not obviously satisfied by the classical construction via charts and pseudodifferential calculus.

The known construction of \( \mu \) with such properties, due to Zelditch and Wolpert (see [43, 42, 18]) and generalized by Silberman–Venkatesh [36], relies heavily upon explicit calculation with raising and lowering operators in the Lie algebra of \( SL_2(\mathbb{R}) \), which have no obvious \( p \)-adic analogue. One point of this paper is to introduce such an analogue and to investigate systematically its relationship to the classical theory of local newvectors. (The restriction to principal series in Theorem 7 then arises for the same reason that Lindenstrauss’s argument does not apply to holomorphic forms of large weight: the absence of a “microlocal lift” invariant by a split torus.) The resulting construction may be of independent interest; for instance, it should have applications to the test vector problem (see §1.5 and Remark 50).

A curious subtlety of the argument, to be detailed further in Remark 26, is that the “lift” we construct is not a lift in the traditional sense (except against spherical observables, and even then only for \( p \neq 2 \)). It instead satisfies a weaker “equidistribution implication” property which suffices for us. This subtlety is responsible for the most technical component of the argument (§6.3).

In the remainder of §1 we formulate our main result in a slightly more general setup (§1.2), introduce a key tool (§1.3), give an overview of the proof (§1.4), interpret our results in terms of \( L \)-functions (§1.5), and record some further remarks and open questions (§1.6).

### 1.2. Main results; general form

In this section we formulate a generalization of Theorem 4 in representation-theoretic language, which we adopt for the remainder of the paper.

**Definition 10.** Define the compact open subgroup

\[
K_{m,m'} := \left[ \begin{array}{cc} \mathfrak{o} & p^{-m} \\ p^m \mathfrak{o} & \mathfrak{o} \end{array} \right] \times \mathfrak{o} := \mathbb{Z}_p, \mathfrak{p} := p\mathbb{Z}_p
\]

(4)
of \( G \). Each such subgroup is conjugate to \( K_{0,n} \) for \( n = m' - m \geq 0 \), which is in turn analogous to the congruence subgroup \( \Gamma(n[p^n]) \) of \( SL_2(\mathbb{Z}) \). Assuming (1), one...
Definition 11. The space $\mathcal{A}(X)$ of smooth functions on $X$ consists of all functions $\varphi : X \to \mathbb{C}$ that are right-invariant under some open subgroup of $G$. An eigenfunction on $X$ is an element $\varphi \in \mathcal{A}(X)$ that is a $T_\ell$-eigenfunction for each $\ell$ and that generates an irreducible representation of $G$ under the right translation action $g\varphi(x) := \mu_{reg}(g)\varphi(x) := \varphi(xg)$. The uniform measure on $X$, denoted simply $\mathcal{L}_X$, is the probability Haar coming from the $G$-action. An element $\varphi \in \mathcal{A}(X)$ is $L^2$-normalized if $\int_X |\varphi|^2 = 1$. In that case, the $L^2$-mass of $\varphi$ is the probability measure $\mu_{\varphi}$ on $X$ given by $\mu_{\varphi}(\Psi) := \int_X |\varphi|^2$. Convergence of measures always refers to the weak sense, i.e., $\lim_{n \to \infty} \mu_n = \mu$ if for each fixed $\Psi \in \mathcal{A}(X)$, $\lim_{n \to \infty} \mu_n(\Psi) = \mu(\Psi)$. A sequence of measures equidistributes if it converges to the uniform measure.

Definition 12. We denote by $\mathcal{H} \subseteq \text{End}(\mathcal{A}(X))$ the ring generated by $\rho(G)$ and the $T_\ell$, so that an eigenfunction in the sense of Definition 11 is an element of $\mathcal{A}(X)$ that generates an irreducible $\mathcal{H}$-submodule. We denote by $\mathcal{A}(X)$ the set of irreducible $\mathcal{H}$-submodules of $\mathcal{A}(X)$, by $A_0(X) \subseteq \mathcal{A}(X)$ the subset consisting of those that are not one-dimensional, and by $A_0(X) \subseteq \mathcal{A}(X)$ the sum of the elements of $A_0(X)$, or equivalently, the orthogonal complement of the one-dimensional irreducible submodules.

A theorem of Eichler/Jacquet–Langlands implies that each $\pi \in \mathcal{A}(X)$ occurs in $\mathcal{A}(X)$ with multiplicity one, so that $\mathcal{A}(X) = \oplus_{\pi \in \mathcal{A}(X)} \pi$ and $A_0(X) = \oplus_{\pi \in A_0(X)} \pi$. The one-dimensional elements of $\mathcal{A}(X)$ are given by $\mathbb{C}(\chi \circ \det)$ for each character $\chi$ of the compact group $\mathbb{Q}_p^\times / \det(\Gamma)$, thus $\mathcal{A}(X) = \{ \mathbb{C}(\chi \circ \det) \} \bigcup A_0(X)$.

Definition 13. Let $\chi_\pi : \mathbb{Q}_p^\times \to \mathbb{C}^\times$ denote the central character of $\pi$. For $\pi \in A_0(X)$, the conductor of $\pi$ has the form $C(\pi) = p^{c(\pi)}$, where $c(\pi)$ is the smallest nonnegative integer with the property that $\pi$ contains a nonzero vector $\varphi$ satisfying $g\varphi = \chi_\pi(d)g$ for all $g = (a \ d) \in K_{0..c(\pi)}$ [8, 33].

Definition 14. Let $\pi \in A_0(X)$. For integers $m, m'$, a vector $\varphi \in \pi$ will be called a newvector of support $m..m'$ if $m' - m = c(\pi)$ and $g\varphi = \chi_\pi(d)\varphi$ for all $g = (a \ d) \in K_{m..m'}$. Local newvector theory [8, 33] implies that the space of such vectors is one-dimensional, so if $\varphi$ is $L^2$-normalized, then the $L^2$-mass $\mu_\varphi$ depends only upon $\pi$ and $m..m'$, not $\varphi$. A vector $\varphi \in \pi$ will be called a generalized newvector if it is a newvector of support $m..m'$ for some $m, m'$. (We include the adjective “generalized” only to indicate explicitly that we are not necessarily referring to the traditional case $m..m' = 0..c(\pi)$, which will play no distinguished role here.)

Remark 15. The newvectors of support $m..m'$ that generate representations with unramified (equivalently, trivial) central character may be characterized more simply as those eigenfunctions $\varphi \in \mathcal{A}(X)$ (in the sense of Definition 11) which

1. are $K_{m..m'}$-invariant, or equivalently, descend to $\varphi : Y_{m..m'} \to \mathbb{C}$, and
2. are orthogonal to pullbacks from $Y_{n..n'}$ whenever $n..n' \leq m..m'$.
Under the torsion-freeness assumption (1), “orthogonal” can be taken to mean with respect to the normalized counting measure on $Y_{m..m'}$; in general, one should take that induced by the uniform measure on $X$. In this sense, Definition 14 is consistent with Definition 1.

**Definition 16.** We say that $\pi \in A_0(X)$ belongs to the principal series if the corresponding representation of $G$ does (see §5.3).

**Theorem 17** (Equidistribution of newvectors, II). Let $\pi \in A_0(X)$ traverse a sequence with $C(\pi \times \pi) \to \infty$. Assume that $\pi$ belongs to the principal series. Let $\varphi \in \pi$ be an $L^2$-normalized generalized newvector. Then $\mu_\varphi$ equidistributes.

Theorem 17 specializes to Theorem 7 upon requiring that $\chi_\pi$ be unramified (equivalently, trivial) and restricting to newvectors of support $m..m' = -N..N$ for some $N$.

**Remark 18.** Unlike earlier works such as [23, 26, 14], we have allowed arbitrary central characters in Theorem 17. We note that the case of the argument in which the conductor of the central character is as large as possible relative to that of the representation is a bit more technically challenging than the others; see (26) and following.

**Remark 19.** Cases of Theorem 17 in which $m..m'$ is highly unbalanced, such as the most traditional case $m..m' = 0..n$ analogous to Theorem 6, are easier: they follow, sometimes with a power savings, from the triple product formula, the convexity bound for triple product $L$-functions, and nontrivial local estimates as in [26, 14]. Cases in which $m..m'$ is balanced, such as the case $m..m' = -N..N$ illustrated in §1.1, do not follow from such local arguments and require the new ideas introduced here. This phenomenon is comparable to how the mass equidistribution on a hyperbolic surface $\Delta \setminus \mathbb{H}$ of a weight $k$ vector in a principal series $\pi \mapsto L^2(\Delta \setminus SL_2(\mathbb{R}))$ of parameter $t \to \infty$ follows from essentially local means for $t/k = o(1)$ but not for $k = 0$, or even for $k \ll t$; see [44, 30] for some discussion along such lines. See also Remark 30 and footnote 10.

1.3. $p$-adic microlocal lifts. We turn to the key definitions that power the proof of the above results. We develop them slightly more precisely and algebraically than is strictly necessary for the consequences indicated above.

Let $k$ be a non-archimedean local field with ring of integers $\mathfrak{o}$, maximal ideal $\mathfrak{p}$, normalized valuation $\nu : k \to \mathbb{Z} \cup \{+\infty\}$, and $q := \#\mathfrak{o}/\mathfrak{p}$. (The case $(k, \mathfrak{o}, \mathfrak{p}, q) = (\mathbb{Q}_p, \mathbb{Z}_p, \mathfrak{p}, q)$ is relevant for the above application.)

To a generic irreducible representation $\pi$ of $GL_n(k)$ one may attach a conductor $C(\pi) = q^c(\pi)$, with $c(\pi) \in \mathbb{Z}_{\geq 0}$. One also defines $c(\omega)$ for each character $\omega$ of $\mathfrak{o}^\times$; it is the smallest integer $n$ for which $\omega$ has trivial restriction to $\mathfrak{o}^\times \cap 1 + \mathfrak{p}^n$.

For context, we record the local form of Definition 14:

**Definition 20 (Newvectors).** A vector $v$ in an irreducible generic representation $\pi$ of $GL_2(k)$ is a newvector of support $m..m'$ if $m' - m = c(\pi)$ and

$$\pi(g)v = \chi_\pi(d)v$$

for all $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(\mathfrak{o}) \cap \begin{bmatrix} \mathfrak{o} & \mathfrak{p}^{-m} \\ \mathfrak{p}^m & \mathfrak{o} \end{bmatrix}$.

A generalized newvector is a newvector of some support.
Fix now for each nonnegative integer $N$ a partition $N = N_1 + N_2$ into nonnegative integers $N_1, N_2$ with the property that $N_1, N_2 \to \infty$ as $N \to \infty$. The precise choice is unimportant; one might take $N_1 := \lfloor N/2 \rfloor, N_2 := \lceil N/2 \rceil$ for concreteness. Using this choice, we introduce the following class of vectors:

**Definition 21** (Microlocal lifts). Let $\pi$ be a $GL_2(k)$-module. A vector $v \in \pi$ shall be called a *microlocal lift* if it generates an irreducible admissible representation of $GL_2(k)$ and if there is a positive integer $N$ and characters $\omega_1, \omega_2$ of $\mathfrak{o}^\times$ so that $c(\omega_1/\omega_2) = N$ and

$$\pi(g)v = \omega_1(a)\omega_2(\det(g)/a)v$$

for all $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2(\mathfrak{o}) \cap \begin{pmatrix} 0 & p^{N_1} \\ p^{N_2} & 0 \end{pmatrix}$.

In that case, we refer to $N$ as the *level* and $(\omega_1, \omega_2)$ as the *orientation* of $v$.

The observation that the special case $\omega_1 = 1$ of Definition 21 is similar to Definition 20 leads easily to the following characterization of microlocal lifts as twists of generalized newvectors from “extremal principal series” representations “$1 \boxplus \chi$” (see §6.1 for the proof):

**Lemma 22.** An irreducible admissible representation $\pi$ of $GL_2(k)$ contains a nonzero microlocal lift if only if $\pi$ is an irreducible principal series representation $\pi \cong \chi_1 \boxplus \chi_2$ for which $N := c(\pi \otimes \pi)/2 = c(\chi_1/\chi_2)$ is nonzero. In that case, the set of microlocal lifts is the union of two distinct lines. One line consists of microlocal lifts of level $N$ and orientation $(\omega_1, \omega_2)$, where $\omega_i := \chi_i|_{\mathfrak{o}^\times}$ explicitly, it is the inverse image under the non-equivariant twisting isomorphism $\pi \to \pi \otimes \chi_1^{-1} \cong 1 \boxplus \chi_1 \chi_2$ of the space of newvectors of support $-N_1..N_2$. The other line is described similarly with the roles of $\omega_1$ and $\omega_2$ reversed.

**Remark 23.** We briefly compare with the archimedean analogue inspiring Definition 21: a more complete exposition of this analogy seems beyond the scope of this article. Let $\pi$ be a principal series representation of $PGL_2(\mathbb{R})$ of parameter $t \to \pm \infty$ with lowest weight vector $\varphi_0$ corresponding to a spherical Maass form of eigenvalue $1/4 + t^2$ on some hyperbolic surface. The Zelditch–Wolpert construction\(^2\) of a microlocal lift $\varphi_1$ of $\varphi_0$ is given up to normalizing factors in terms of standard raising/lowering operators $X^n$ for $n \in \mathbb{Z}$ (see [42, 18]) by $\varphi_1 := \sum_{n:|n| \leq t_1} X^n \varphi_0$, where $|t| = t_1t_2 \to \infty$ as $|t| \to \infty$. The choice $\varphi_2 := \sum_{n:|n| \leq t_2} (-1)^n X^n \varphi_0$ also works. The analogue of $(|t|, \varphi_1, \varphi_2, |\cdot| \varphi_1, |\cdot|^{-\varphi_1})$ in the notation of Definition 21 and Lemma 22 is $(q^n, v_1, v_2, \chi_1, \chi_2)$ with $q := \#\mathfrak{o}/p$ and $v_1, v_2 \in \pi$ microlocal lifts of respective orientations $(\omega_1, \omega_2)$, $(\omega_2, \omega_1)$. The analogy may be obtained by comparing how $GL_2(\mathfrak{o})$ acts on $v_1, v_2$ to how the Lie algebra of $PGL_2(\mathbb{R})$ acts on $\varphi_1, \varphi_2$. The factorization $|t| = t_1t_2$ is roughly analogous to the partition $N = N_1 + N_2$. It is also instructive to compare the formulas for $\varphi_1, \varphi_2$ in their induced models with those of §6.2.

**Remark 24.** Le-Masson [17] and Anantharaman–Le-Masson [1] have introduced a notion of microlocal lifts on regular graphs and used that notion to prove some analogues of the quantum ergodicity theorem. Definition 21 serves different aims in that we do not explicitly vary the graph (except perhaps in the second sense.

\(^2\) We discuss here only the “positive measure” incarnation of that construction rather than the “distributional” one.
indicated in Remark 8); it would be interesting to extend it further and compare the two notions on any domain of overlap.

For the remainder of §1.3, take \( k = \mathbb{Q}_p \), so that \( \text{GL}_2(k) = G \). Definition 21 applies to \( \pi \in A_0(X) \).

**Theorem 25** (Basic properties of microlocal lifts). Let \( N \) traverse a sequence of positive integers tending to \( \infty \), and let \( \varphi \in \pi \in A_0(X) \) be an \( L^2 \)-normalized microlocal lift of level \( N \) on \( X \) with \( L^2 \)-mass \( \mu_\varphi \).

- **Diagonal invariance.** Any weak subsequential limit of the sequence of measures \( \mu_\varphi \) is a \((\mathbb{Q}_p \times \mathbb{Q}_p)\)-invariant.
- **Lifting property.** Suppose temporarily that \( p \neq 2 \), so that \( v(2) = 0 \). Let \( \varphi' \in \pi \) be an \( L^2 \)-normalized newvector of support \(-N, N\), and let \( \Psi \in \mathcal{A}(X)^K \) be independent of \( N \) and right invariant by \( K := \text{GL}_2(\mathbb{Z}_p) \). Then
  \[
  \lim_{N \to \infty} (\mu_\varphi(\Psi) - \mu_{\varphi'}(\Psi)) = 0.
  \]
- **Equidistribution implication.** Suppose that \( \mu_\varphi \) equidistributes as \( N \to \infty \). Let \( \varphi' \in \pi \) be an \( L^2 \)-normalized generalized newvector. Then \( \mu_{\varphi'} \) equidistributes as \( N \to \infty \).

Theorem 25 is established in §7 after developing the necessary local preliminaries in §5 and §6. The proof involves uniqueness of invariant trilinear forms on \( \text{GL}_2 \) and stationary phase analysis of local Rankin–Selberg integrals. Theorem 25 is essentially local, i.e., does not exploit the arithmeticity of \( \Gamma \leq G \), and is stated here in a global setting only for convenience; see Theorem 49 for a local analogue.

**Remark 26.** The “lifting property” of Theorem 25 has been included only for the sake of illustration; it is not strictly necessary for the logical purposes of this paper. We have assumed \( p \neq 2 \) in its statement because the corresponding assertion is false when \( p = 2 \). For general \( p \) and non-spherical observables \( \Psi \), there does not appear to be any simple relationship between the quantities \( \mu_\varphi(\Psi) \) and \( \mu_{\varphi'}(\Psi) \) except that convergence to \( \int_X \Psi \) of the first implies that of the second (the “equidistribution implication”). The “lifting” relationship here is thus more subtle than that in [20].

1.4. **Equidistribution of microlocal lifts.** Our core result (from which the others are ultimately derived) is the following:

**Theorem 27** (Equidistribution of microlocal lifts). Let \( N \) traverse a sequence of positive integers tending to \( \infty \). Let \( \varphi \in \mathcal{A}(X) \) be an \( L^2 \)-normalized microlocal lift of level \( N \) on \( X \). Then \( \mu_\varphi \) equidistributes.

The proof depends upon an analogue of Lindenstrauss’s celebrated result [20]:

**Theorem 28** (Measure classification). Let \( \mu \) be a probability measure on \( X \), invariant by the center of \( G \), with the properties:

1. \( \mu \) is \( a(\mathbb{Q}_p^\times) \)-invariant.
2. \( \mu \) is \( T_\ell \)-recurrent for some split prime \( \ell \neq p \).

\[\text{It should be possible to avoid this comparatively deep fact in the proof of the first part of Theorem 25, but it is required by the application to subconvexity (Theorem 29), and the calculations required by that application already suffice here.}\]
(3) The entropy of almost every ergodic component of $\mu$ is positive for the $a(\mathbb{Q}_p^\times)$-action. Then $\mu$ is the uniform measure.

We explain in §2 the specialization of Theorem 28 from a result of Einsiedler–Lindenstrauss [11, Thm 1.5]. To deduce Theorem 27, we apply Theorem 28 with $\mu$ any weak limit of a sequence of $L^2$-normalized microlocal lifts of level tending to $\infty$. Since $X$ is compact, $\mu$ is a probability measure. The invariance hypothesis follows from the diagonal invariance of Theorem 25, while the $T_\ell$-recurrence and positive entropy hypotheses are verified below in §3 and §4. The proof of our main result Theorem 27 is then complete. Theorem 27 and the equidistribution implication of Theorem 25 imply Theorem 17.

1.5. Estimates for $L$-functions. For definitions of the $L$-functions and local distinguishedness see [27, 15]. We record the following because it provides an unambiguous benchmark of the strength of our results.

**Theorem 29** (Weakly subconvex bound). Fix $\sigma \in A_0(X)$. Let $\pi \in A_0(X)$ traverse a sequence with $C(\pi \times \pi) \to \infty$. Assume that $\pi$ belongs to the principal series and that $\sigma \otimes \pi \otimes \pi$ is locally distinguished. Then

$$\frac{L(\sigma \times \pi \times \pi, 1/2)}{L(\text{ad} \, \pi, 1)^2} = o(C(\sigma \times \pi \times \pi)^{1/4}).$$

(5)

The previously best known estimate for the LHS of (5) is the general weakly subconvex estimate of Soundararajan [37], specializing here to $L \ll C^{1/4}/(\log C)^{1-\varepsilon}$ with $L := L(\sigma \times \pi \times \pi, 1/2), C := C(\sigma \times \pi \times \pi)$. The bound (5) improves upon that estimate in the unlikely (but difficult to exclude) case that $L(\text{ad} \, \pi, 1)$ is exceptionally small, which turns out to be the most difficult one for equidistribution problems; see [13] for further discussion.

Theorem 27 implies Theorem 29 after a local calculation with the triple product formula (see §7); in fact, the calculation shows that the two results are equivalent.

**Remark 30.** Theorem 29 implies Theorem 17, but the converse does not hold in general; a special case of the failure of that converse was noted and discussed at length in [26, §1]. The present work may thus be understood as clarifying that discussion: the equivalence between subconvexity and equidistribution problems in the depth aspect is restored by working not with newvectors, but instead with the $p$-adic microlocal lifts introduced here.

1.6. Further remarks.

**Remark 31.** Theorems 17 and 27 apply only to sequences of vectors $\varphi$ that generates irreducible $\mathcal{H}$-modules. One can ask whether the conclusion holds under the (hypothetically) weaker assumption that $\varphi$ generates an irreducible $G$-module. The problem formulated this way makes sense for any finite volume quotient $\Gamma \backslash G$, not necessarily arithmetic; an affirmative answer would represent a $p$-adic analogue of the Rudnick–Sarnak quantum unique ergodicity conjecture [31]. In that direction, we note that the method of Brooks–Lindenstrauss [6] should apply in our setting, allowing one to relax the hypothesis of irreducibility under the full Hecke algebra to that under a single auxiliary Hecke operator $T_\ell$ for some fixed split prime $\ell \neq p$. 
Remark 32. Our results apply to principal series representations of conductor $p^N$ with $p$ fixed and $N \to \infty$. A natural question is whether one can establish analogous results for $N$ fixed, such as $N = 100$, and $p \to \infty$. We highlight here the weaker question of whether one can establish equidistribution (in a balanced case, cf. Remark 19) as $N \to \infty$ for $p$ satisfying $p \leq p_0(N)$ for some $p_0(N)$ tending effectively to $\infty$ as $N \to \infty$. Our results and a diagonalization argument imply an ineffective analogue.

Remark 33. The crucial local results of this article have been formulated and proved in generality, i.e., over any non-archimedean local field. On the other hand, we have assumed in our global results that the subgroup $\Gamma$ of $G$ was constructed from a maximal order in a quaternion algebra over $\mathbb{Q}$. We expect that our results hold more generally:

1. The statements and proofs of all our results except Theorem 29 extend straightforwardly to the case that $\Gamma$ arises from a fixed Eichler order in a quaternion algebra over $\mathbb{Q}$. To extend Theorem 29 in that direction would require some local triple product estimates at the “uninteresting” primes $\ell \neq p$ which we do not pursue here.

2. Our results should extend to Eichler orders in totally definite quaternion algebras over totally real number fields, but some mild care is required in formulating such extensions when the class group has nontrivial 2-torsion: as observed in a related context in [24], there are sequences of dihedral forms that fail to satisfy the most naive formulation of quantum unique ergodicity.

3. We expect our results extend to automorphic forms on definite quaternion algebras having fixed nontrivial infinity type; such an extension would require a more careful study of the measure classification input in §2.

4. Over function fields, analogues of our results should follow more directly and in quantitatively stronger forms from Deligne’s theorem and extensions of the triple product formula to the function field setting.

We leave such extensions to the interested reader.

Organization of this paper. We verify the measure-classification (Theorem 28) and its hypotheses in §2, §4. We review the representation theory of $GL_2(k)$ in §5. In §6 and §7, we prove our core results, notably Theorem 25, and their applications. Some additional results of independent interest are recorded along the way.

Acknowledgements. This paper owes an evident debt of ideas and inspiration to E. Lindenstrauss’s work [20]; we thank him also for helpful feedback and interest. We thank M. Einsiedler for helpful discussions on measure classification and feedback on an earlier draft, P. Sarnak and A. Venkatesh for several helpful discussions informing our general understanding of microlocal lifts and microlocal analysis, A. Saha for helpful references concerning conductors, S. Jana for feedback on entropy bounds, Y. Hu for helpful clarifying questions, and E. Kowalski, Ph. Michel and D. Ramakrishnan for encouragement. We gratefully acknowledge the support of NSF grant OISE-1064866 and SNF grant SNF-137488 during the work leading to this paper.
MICROLOCAL LIFTS AND QUANTUM UNIQUE ERGODICITY ON GL_2(\mathbb{Q}_p)

2. Measure classification

The purpose of this section is to deduce Theorem 28 from the following specialization to \( \mathbb{Q}_p \) of a result of Einsiedler–Lindenstrauss [11, Thm 1.5]:

**Theorem 34.** Let \( G = G_1 \times G_2 \), where \( G_1 \) is a semisimple linear algebraic group over \( \mathbb{Q}_p \) with \( \mathbb{Q}_p \)-rank 1 and \( G_2 \) is a characteristic zero \( S \)-algebraic group. Let \( \Delta \subset G \) be a discrete subgroup. Let \( A_1 \) be a \( \mathbb{Q}_p \)-split torus of \( G_1 \) and let \( \chi \) be a nontrivial \( \mathbb{Q}_p \)-character of \( A_1 \) that can be extended to \( C_{G_1}(A_1) \). Let \( M_1 = \{ h \in C_{G_1}(A_1) : \chi(h) = 1 \} \). Let \( \nu \) be an \( A_1 \)-invariant, \( G_2 \)-recurrent probability measure on \( \Delta \setminus G \) such that

1. almost every \( A_1 \)-ergodic component of \( \nu \) has positive ergodic theoretic entropy with respect to some \( a \in A_1 \) with \( |\chi(a)| \neq 1 \), and
2. for \( \nu \)-a.e. \( x \in \Delta \setminus G \), the group \( \{ h \in M_1 \times G_2 : xh = x \} \) is finite.

Then \( \nu \) is a convex combination of homogeneous measures, each of which is supported on an orbit of a subgroup \( H \) which contains a finite index subgroup of a semisimple algebraic subgroup of \( G_1 \) of \( \mathbb{Q}_p \)-rank one.

To deduce Theorem 28 from Theorem 34 requires no new ideas, but we record a complete verification for completeness.

2.1. Consequences of strong approximation. Recall that \( R \) is a maximal order in a definite quaternion algebra \( B \). For a prime \( p \), we shall use the notations \( B_p := B \otimes_{\mathbb{Q}} \mathbb{Q}_p \), \( R_p := R \otimes_{\mathbb{Z}} \mathbb{Z}_p \). A superscripted (1) denotes “norm one elements,” e.g., \( B_p^{(1)} := \{ b \in B_p^\times : \text{nr}(b) = 1 \} \). Denote by \( \mathbb{A}_f \) the finite adele ring of \( \mathbb{Q} \) and \( \hat{B} := B \otimes_{\mathbb{Q}} \mathbb{A}_f \). Regard \( B^\times, B_p^\times, R_p^\times \) as subsets of \( \hat{B}^\times \) in the standard way.

**Lemma 35.** Let \( H \) be a subgroup of \( \hat{B}^\times \) for which:

1. There is a prime \( p \) that splits \( B \) for which \( H \) contains an open subgroup of \( B_p^{(1)} \) containing \( B_p^{(1)} \).
2. The image \( \text{nr}(H) \) of \( H \) under the reduced norm \( \text{nr} : \hat{B}^\times \rightarrow \mathbb{A}_f^\times \) satisfies \( \mathbb{Q}_p^\times \text{nr}(H) = \mathbb{A}_f^\times \).

Then \( B^\times H = \hat{B}^\times \).

**Proof.** It is known that \( \text{nr} : B^\times \rightarrow \mathbb{Q}_p^\times \) is surjective. Let \( b \in \hat{B}^\times \) be given. By (ii), there exists \( \gamma \in B^\times \) and \( h \in H \) for which \( \gamma b h \in \hat{B}^{(1)} \). Let \( p \) be as in (i). Strong approximation for the simply-connected semisimple algebraic group \( B^{(1)} \) and its non-compact factor \( B_p^{(1)} \) implies that \( B^{(1)} B_p^{(1)} \) is dense in \( \hat{B}^{(1)} \). By (i), we may write \( \gamma b h = \delta h' \) for some \( \delta \in B^{(1)} \) and \( h' \in H \). Therefore \( b = \gamma^{-1} \delta h' h^{-1} \) belongs to \( B^\times H \), as required. \( \square \)

Let \( p \) be a split prime for \( B \). For any prime \( \ell \), one has \( \text{nr}(B_\ell^\times) = \mathbb{Q}_\ell^\times \); because \( R \) is a maximal order (in particular, an Eichler order), one has moreover that \( \text{nr}(R_\ell^\times) = \mathbb{Z}_\ell^\times \). The hypotheses of Lemma 35 thus apply to \( H = B_p^\times \prod_{\ell \neq p} R_\ell^\times \): (i) is clearly satisfied, while (ii) follows from the consequence \( \mathbb{Q}_+^\times \mathbb{Q}_p^\times \prod_{\ell \neq p} \mathbb{Z}_\ell^\times = \mathbb{A}_f^\times \) of strong approximation for the ideles. For similar but simpler reasons, the hypotheses apply also to \( H = B_\ell^\times B_p^\times \prod_{q \neq \ell, p} R_q^\times \). Thus

\[
B^\times B_p^\times \prod_{\ell \neq p} R_\ell^\times = \hat{B}^\times = B_p^\times B_\ell^\times B_p^\times \prod_{q \neq \ell, p} R_q^\times.
\]
We have $B^x \cap \prod_{\ell \neq p} \hat{R}_\ell^x = R[1/p]^x$ and $B^x \cap \prod_{q \neq \ell, p} \hat{R}_q^x = R[1/p]\ell]^x$, whence the natural identifications

$$R[1/p]^x \backslash B_p^x / Q_p^x = B^x \backslash B^x / Q_p^x \prod_{\ell \neq p} \hat{R}_\ell^x = R[1/p\ell]^x \backslash B_p^x / Q_p^x R_\ell^x.$$  \hspace{1cm} (6)

Since $\mathbb{Z}[1/p]^x Q_p^x \mathbb{Z}_\ell^x = Q_p^x \mathbb{Z}_\ell^x$, the RHS of (6) is unaffected by further reduction modulo $Q_\ell^x$, i.e.,

$$R[1/p]^x \backslash B_p^x / Q_p^x = R[1/p\ell]^x \backslash B_p^x / Q_p^x Q_\ell^x R_\ell^x.$$  \hspace{1cm} (7)

2.2. Deduction of Theorem 28. Let $p$ be a split prime for $B$. Identify $B_p^x = \text{GL}_2(\mathbb{Q}_p)$ and $X = \Gamma \backslash \text{GL}_2(\mathbb{Q}_p)$ as in §1. Let $\mu$ be a measure on $X$ satisfying the hypotheses of Theorem 28. It is invariant under the diagonal torus of $\text{SL}_2(\mathbb{Q}_p)$, so to prove that $\mu$ is the uniform measure, we need only verify that it is $\text{SL}_2(\mathbb{Q}_p)$-invariant. To that end, we apply Theorem 34: Set $G_1 := \text{PGL}_2(\mathbb{Q}_p) = B^x_p / Q_p^x$, $G_2 := \text{PGL}_2(\mathbb{Q}_p) = B^x / Q_p^x$, $G := G_1 \times G_2$. Recall that $\Gamma = R[1/p]^x$. Take for $\Delta$ the image of $R[1/p\ell]^x$ in $G$. By strong approximation in the form (7), we may identify $\Gamma \backslash \text{GL}_2(\mathbb{Q}_p)/\Delta(G)$ with $\Delta \backslash \text{PGL}_2(\mathbb{Z}_\ell)$ and $\mu$ with a right $\text{PGL}_2(\mathbb{Z}_\ell)$-invariant measure $\nu$ on $\Delta(G).$ Our task is then to verify that $\nu$ is invariant by the image of $\text{SL}_2(\mathbb{Q}_p).$ Take for $A_1$ the diagonal torus in $G_1$ and for $\chi : A_1 \to \mathbb{Q}_p^\times$ the map $\chi(\text{diag}(y_1, y_2)) := y_1/y_2$. We have $C_G(A_1) = A_1$. The group $M_1$ is trivial, hence each $\{h \in M_1 \times G_2 : xh = x\}$ is trivial. The hypotheses of Theorem 28 are satisfied, so $\nu$ is invariant by some finite index subgroup $H_1$ of some semisimple algebraic subgroup of $G_1$ (of $\mathbb{Q}_p$-rank one) that contains $A_1$. The smallest such $H_1$ is the image of $\text{SL}_2(\mathbb{Q}_p)$, so we conclude.

3. Recurrence

In this section we formulate and verify the $T_\ell$-recurrence hypothesis required by Theorem 28. The argument here is as in [20, §8] except that we allow general central characters; for completeness, we record a proof of the key estimate in that case. The proof is simple; a key insight of Lindenstrauss [20] is that the condition enunciated here is useful for the present purposes.

3.1. Hecke operators. For a positive integer $n$ coprime to $p$, the Hecke operator $T_n \in \text{End}(\mathcal{A}(X))$ is defined by $T_n \varphi(x) := \sum_{\alpha \in M_n/M_1} \varphi(\alpha^{-1}x)$, where $M_n := R[1/p] \cap n^{-1}(n\mathbb{Z}[1/p]^x)$, so that $M_1 = \Gamma$. These operators commute with one another and also with $\rho_{\text{reg}}(G)$. If $\ell \mid \text{disc } B$, then the operator $T_\ell$ is an involution modulo the action of the center; otherwise, it is induced by a correspondence of degree $\ell + 1$. For $m \in \mathbb{Q}_p^\times$, abbreviate $z(m) := \rho_{\text{reg}}(z(m))$ (see §1.3 for notation). The adjoint of $T_n$ is $T_n^* = z(n)T_n$, and one has the composition formula

$$T_mT_n = \sum_{d \in \mathbb{Z}_\ell^*} d \cdot z(d^{-1})T_{mn/d^2}.$$  \hspace{1cm} (8)

3.2. Spherical averaging operators. Let $n$ be a positive integer coprime to $p$. The operator $T_n$ on $\mathcal{A}(X)$ is induced by the correspondence on $X$, denoted also by $T_n$, given for $x \in X$ by the multiset (i.e., formal sum) $T_n(x) := \sum_{s \in M_n/\Gamma} s^{-1}x$. Thus $T_n \varphi(x) = \sum_{y \in T_n(x)} \varphi(y)$. Denote by $M_n^\text{pr}$ the set of all primitive elements of $M_n,$ i.e., those that are not divisible inside $R[1/p]$ by any divisor $d > 1$ of $n$. Then
Correspondence $S_n(x) := \sum_{s \in M_{n, T}^\text{prim}} s^{-1} x$; it likewise induces an operator $S_n$ on $A(X)$ given by $S_n \varphi(x) := \sum_{s \in M_{n, T}^\text{prim}} \varphi(s^{-1} x) = \sum_{y \in S_n(x)} \varphi(y)$, and one has
\[ T_n(x) = \sum_{d | n} \varphi(d^{-1}) S_n/d \varphi(x). \] (9)

3.3. Recurrence. Let $\ell \neq p$ be a split prime, that is to say, a prime that splits the quaternion algebra underlying the construction of $\Gamma$, so that the Hecke operator $T_{\ell}$ has degree $\ell + 1$.

Definition 36. A finite $Z$-invariant measure $\mu$ on $X$ is called $T_{\ell}$-recurrent if for each Borel subset $E \subseteq X$ and $\mu$-almost every $x \in E$, there exist infinitely many positive integers $n$ for which $S_n(x) \cap E \neq \emptyset$.

Theorem 37 (Hecke recurrence). Let $\mu$ be any subsequential limit of a sequence of $L^2$-masses $\mu_\varphi$ of $L^2$-normalized automorphic forms $\varphi \in \pi \in A_0(X)$. Then $\mu$ is $T_{\ell}$-recurrent.4

The proof of Theorem 37 reduces via measure-theoretic considerations as in [20, 6] to that of the following:

Lemma 38. There exists $c_0 > 0$ so that for each split prime $\ell$ and $\varphi \in \pi \in A_0(X)$ and $x \in X$, one has $\sum_{k \leq n} \varphi(y)^2 \geq c_0 n |\varphi(x)|^2$.

Proof. By a theorem of Eichler, Shimura and Igusa, $\pi$ is tempered, hence there exist $\alpha, \beta \in \mathbb{C}^{(1)}$ (the Satake parameters) so that $\lambda_\pi(\ell) = \alpha + \beta$; one then has more generally for $n \in \mathbb{Z}_{\geq 1}$ that
\[ \lambda_\pi(\ell^n) = \frac{\alpha^{n+1} - \beta^{n+1}}{\alpha - \beta}. \] (10)

By (9), one has $T_{\ell^n} = \sum_{k \leq n : k \equiv n(2)} z((\ell+2)/2) S_{\ell^k}$. Conversely, $S_{\ell^k} = T_{\ell^k} - 1_{k \geq 2} z((\ell-1)/2) T_{\ell^k-2}$. Since $\pi$ has a unitary central character, there is $\theta \in \mathbb{C}^{(1)}$ so that $z((\ell-1)/2) \varphi = \theta \varphi$ for all $\varphi \in \pi$. Thus, denoting by $\ell^k/2 \sigma_k \in \mathbb{C}$ the scalar by which $S_{\ell^k}$ acts on $\pi$, one obtains $\sigma_k = \lambda(\ell^k) - 1_{k \geq 2} \theta \ell^{k-1} \lambda(\ell^{k-2})$, which expands for $k \geq 2$ to
\[ \sigma_k = \frac{\gamma_1 \alpha^k - \gamma_2 \beta^k}{\alpha - \beta}. \] (11)

with $\gamma_1 := \alpha - \theta \ell^{-1} \alpha, \gamma_2 := \beta - \theta \ell^{-1} \beta$. Note that $|\gamma_1|, |\gamma_2| \geq 1/2$.

We turn to the main argument. For $m, k \in \mathbb{Z}_{\geq 0}$, Cauchy–Schwarz gives
\[ \ell^m |\lambda_\pi(\ell^m) \varphi(x)|^2 = |T_{\ell^m} \varphi(x)|^2 \leq (1 + \ell^{-1}) \ell^m \sum_{y \in T_{\ell^m} \varphi(x)} |\varphi(y)|^2, \]
\[ \ell^k |\sigma_k \varphi(x)|^2 = |S_{\ell^k} \varphi(x)|^2 \leq (1 + \ell^{-1}) \ell^k \sum_{y \in S_{\ell^k} \varphi(x)} |\varphi(y)|^2, \]
whence by (9) that $\sum_{k \leq n} \varphi(y)^2 \geq |\varphi(x)|^2 c_{\pi, \ell}(n)$ with
\[ c_{\pi, \ell}(n) := \sum_{k \leq n} |\sigma_k|^2 + \max_{m \leq n} |\lambda_\pi(\ell^m)|^2. \] (12)

4It suffices to assume only that $\varphi$ is a $T_\ell$-eigenfunction.

5As in the references, the non-tempered case may be treated more simply.
Our task thereby reduces to verifying that \( c_{\pi,\ell}(n) \gg n \), uniformly in \( \pi \) and \((\text{unimportantly}) \ell \). Suppose this estimate fails. Then there is a sequence of integers \( j \to \infty \) and tuples \((\pi, n, \ell) = (\pi_j, n_j, \ell_j)\) as above, depending upon \( j \), so that \( n \to \infty \) as \( j \to \infty \) and \( c_{\pi,\ell}(n) = o(n) \). Here asymptotic notation refers to the \( j \to \infty \) limit, and for quantities \( A, B = A_j, B_j \) depending (implicitly) upon \( j \), we write \( A \ll B \) for \( \limsup_{j \to \infty} |A_j/B_j| < \infty \) and \( A \ll B \) or \( A = o(B) \) for \( \limsup_{j \to \infty} |A_j/B_j| = 0 \); the notations \( A \gg B \) and \( A \gg B \) are defined symmetrically. We shall derive from this supposition a contradiction. By passing to subsequences, we may consider separately cases in which the Satake parameters \( \alpha, \beta \) of \( \pi \), as defined above, satisfy (i) \( |\alpha - \beta| \gg 1/n \) or (ii) \( |\alpha - \beta| \ll 1/n \). In case (i), we have \( |1 - \alpha\beta|^{-1} \ll n \), and so upon expanding the square and summing the geometric series,

\[
c_{\pi,\ell}(n) \geq \sum_{k \leq n} |\sigma_k|^2 \geq \frac{|\gamma_1|^2 n + |\gamma_2|^2 n + o(n)}{|\alpha - \beta|^2} \geq \frac{n/3}{|\alpha - \beta|^2} \gg n.
\]

In case (ii), one has \( |\alpha - \beta|^{-1}/10 \gg n \), so the largest positive integer \( m \leq n \) for which \( m|\alpha - \beta| < 1/10 \) satisfies \( m \gg n \), and (10) gives \( c_{\pi,\ell}(n) \geq |\lambda_\pi(\ell m)|^2 \gg m^2 \gg n^2 \geq n \). In either case, we derive the required contradiction. \( \square \)

4. Positive entropy

In this section we verify the entropy hypothesis required by Theorem 28. The basic ideas here are due to Bourgain–Lindenstrauss [2] following earlier work of Rudnick–Sarnak [31] and Lindenstrauss [18] and followed by later developments of Silberman–Venkatesh [35] and Brooks–Lindenstrauss [6]. Those works dealt with archimedean aspects; the present \( p \)-adic adaptation is obtained by replacing the role played by the discreteness of \( \mathbb{Z} \) in \( \mathbb{R} \) with that of \( \mathbb{Z}[1/p] \) in \( \mathbb{R} \times \mathbb{Q}_p \). We also give a new formulation of the basic line of attack (Lemma 41) emphasizing convolution over covering arguments (compare with [35, Lemma 3.4]), which may be of use in other contexts.

Call \( \varepsilon > 0 \) admissible if it belongs to the image of \( |.| : \mathbb{Q}_p^\times \to \mathbb{R}^\times \). For a compact open subgroup \( C \subseteq \mathbb{Q}_p^\times \) and admissible \( \varepsilon > 0 \) set

\[
B(C, \varepsilon) := \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in G : a, d \in C, |b|, |c| \leq \varepsilon \}.
\]

We refer to [19, §8] for definitions and basic facts concerning measure-theoretic entropy. As in [19, §8] or [2] or [35, Thm 6.4], the following criterion suffices:

**Theorem 39** (Positive entropy on almost every ergodic component). For each compact subset \( \Omega \) of \( G \) there exists \( C \) as above and \( C_1, C_2 > 0 \) so that for all admissible \( \varepsilon \in (0, 1) \), all \( L^2 \)-normalized \( \varphi \in \pi \in A_0(X) \), and all \( x \in \Omega \), one has \( \mu_\varphi(xB(C, \varepsilon)) \leq C_1 \varepsilon^{c_2} \).

Given \( \Omega \), we choose for \( C \) any open subgroup of \( \mathfrak{o}^\times \) with the property that for small enough \( \varepsilon \), one has

\[
xB(C, \varepsilon)x^{-1} \subseteq K \quad \text{for all } x \in \Omega, \quad \text{(13)}
\]

\[
gB(C, \varepsilon)g^{-1} \cap \Gamma = \{1\} \quad \text{for all } g \in G \quad \text{(14)}
\]

\[\text{and (13) holds for all } x \in \Omega.\]

\[\text{and (14) holds for all } g \in G.\]
the latter being possible because $B$ is non-split. We now state two independent lemmas, prove Theorem 39 assuming them, and then prove the lemmas.

**Lemma 40** (Bounds for Hecke returns). For all admissible $\varepsilon \in (0,1)$, all $n \in \mathbb{Z}_{\geq 1}$ coprime to $p$ and satisfying $n < \sqrt{1/2} \varepsilon^{-1}$, all $m \in \mathbb{Q}^\times$ with numerator and denominator coprime to $p$, and all $x \in \Gamma$, the set $S := M_n \cap z(m)xB(C,\varepsilon)x^{-1}$ has cardinality $#S \leq 6 \prod_{p | \nu} (k + 1)$. In particular, $#S \leq 2^{13}$ if $n$ has at most 10 prime divisors counted with multiplicity.

**Lemma 41** (Geometric amplification). Let $(c_\ell)_{\ell \in \mathbb{Z}_{\geq 1}}$ be a finitely-supported sequence of scalars. Set $T := \sum_{\ell} c_\ell T_\ell/\sqrt{\ell}$ and $T^a := \sum_{\ell} |c_\ell| T_\ell^a/\sqrt{\ell}$. Let $\varphi \in \mathcal{A}(\mathbb{X})$, $\psi, \nu \in C_c^\infty(G)$. Define $\Psi \in \mathcal{A}(\mathbb{X})$ by $\Psi(g) := \sum_{\gamma \in \Gamma} |\psi(\gamma g)|$ and $\psi \ast \nu \in C_c^\infty(G)$ by $\psi \ast \nu(x) := \int_{y \in G} \psi(xy) \nu(y)$. Then $$\|T \varphi(\psi \ast \nu)\|_{L^2(G)} \leq \|\varphi\|_{L^2(\mathbb{X})} \|T^a \Psi\|_{L^2(\mathbb{X})} \|\nu\|_{L^2(G)}.$$  

**Proof of Theorem 39.** We have $T \varphi = \lambda \varphi$ with $\lambda := \sum c_\ell \lambda_\varphi(\ell)$ where $T_\ell \varphi = \sqrt{\ell} \lambda_\varphi(\ell) \varphi$. Abbreviate $J := B(\mathbb{C}, \varepsilon)$; it is a group. Let $x \in \Omega$. Take $\psi := 1_{xB(\mathbb{C}, \varepsilon)} \geq 0$ and $\nu := e_J := \text{vol}(J)^{-1}1_J$. Then $1_{xB(\mathbb{C}, \varepsilon)} = |\psi \ast \nu|^2$. By (14), we have $\mu_T \varphi(\psi \ast \nu) = \|T \varphi(\psi \ast \nu)\|_{L^2(G)}^2$, and so by Lemma 41, $\mu_T (\psi \ast \nu) \leq \|\psi \ast \nu\|_{L^2(G)}$. The square $\|T \varphi(\psi \ast \nu)\|_{L^2(G)}^2$ is a linear combination of terms $(T_\ell \varphi, T_\ell \Psi, \nu) = (T_\ell \varphi, T_\ell \Psi, \nu)$ to which we apply the Hecke multiplicity (8) and the unfolding: for $m, n \in \mathbb{Z}_{\geq 1}$,

$$\langle z(m)T_n \varphi, \Psi \rangle \|\nu\|_{L^2(G)}^2 = \int_{g \in G} \sum_{s \in M_n} \psi(z(m)sg)\psi(g) \text{vol}(J)^{-1}$$

$$= #M_n \cap z(m^{-1})xJx^{-1}.$$  

By Lemma 40, we thereby obtain

$$\mu_T (xB(\mathbb{C}, \varepsilon))^2 \leq 2^{13} |\lambda|^{-2} \sum_{\ell, \ell'} |c_\ell c_{\ell'}| \sum d/\ell \sqrt{\ell}$$

provided that $c_\ell$ is supported on integers $\ell \leq 2^{-1/4} \varepsilon^{-1/2}$ having at most 5 prime factors counted with multiplicity. A standard choice of $c_\ell$ completes the proof. For completeness, we record a variant of the choice from [40, §4.1]: Set $L := (1/\varepsilon)^{0.1}$. Denote by $\mathcal{L}$ the set consisting of all $\ell = q$ or $\ell = q^2$ taken over primes $q \in [L, 2L]$; each such $q$ splits $B$ provided $\varepsilon$ is small enough. Set $c_\ell := 0$ unless $\ell \in \mathcal{L}$, in which case $c_\ell := L^{-1} \log(L) \text{sgn}(\lambda_\varphi(\ell))^{-1}$. We have $\sum_{\ell} |c_\ell| \approx 1$ and $|c_\ell| \leq L^{-1} \log(L)$, while Iwaniec’s trick $|\lambda_\varphi(q)|^2 + |\lambda_\varphi(q^2)| \geq 1$, a consequence of (8), implies $\lambda \gg 1$. With trivial estimation we obtain $\mu_T (xB(\mathbb{C}, \varepsilon)) \ll L^{-1/2} \log(L) \ll \varepsilon^{10.1}$, as required.

**Proof of Lemma 40.** Observe first, thanks to (13) and $n \mathbb{Z}[1/p]^\times \cap (\mathbb{Q}^\times \times \mathbb{Z}_p) = \{ n \}$ and $z(m) \in K$, that $S \subseteq M_n \cap K = R(n) := \{ \alpha \in R : \nu r(\alpha) = n \}$. Given $s, t \in S$, their commutator $u := st s^{-1} t^{-1}$ thus satisfies $\nu r(u) = 1$ and $n^2 u = sts t^{-1} \in R$, hence $\text{tr}(u) \in n^{-2} \mathbb{Z}$. Since $S$ is conjugate to a subset of the preimage in $M_2(\mathbb{O})$ of the upper-triangular Borel in $M_2(\mathbb{O}/q)$ with $q := \{ x \in \mathbb{O} : |x| \leq \varepsilon^2 \}$, and the commutator of that preimage is contained in the preimage of the unipotent, one has $|\text{tr}(u) - 2| \leq \varepsilon^2$. Since $B$ is definite, $|\text{tr}(u)|_{\infty} \leq 2 |\nu r(u)|_{1/2} = 2$. The integer $a := n^2 \text{tr}(u) - 2n^2$ thus satisfies $|a|_{\infty} |a|_p \leq 2n^2 \varepsilon^2 < 1$ and so must be zero, i.e., $\text{tr}(u) = 2$; since $B$ is non-split, $u = 1$. In summary, any two elements of $S$ commute. Since $B$ is non-split and definite, $S$ is contained in the set $\mathcal{O}(n)$ of norm $n$ elements.
in some imaginary quadratic order $O \subset R$. Thus $\# S \leq \# O(n) \leq \# O^\times \cdot \# \{ I \subseteq O : \text{nr}(I) = n \} \leq 6 \prod_{p || n} (k + 1)$. \hfill \Box

Proof of Lemma 41. Write $M := R[1/p]$. We may express the operator $T$ by the formula $T \varphi(x) = \sum_{s \in M / \Gamma} h_s \varphi(s^{-1}x)$ for some finitely supported coefficients $h_s$; then $T^\alpha \Psi(x) = \sum_{s \in M / \Gamma} |h_s| \Psi(sx)$. Abbreviate $I := \| T \varphi (\psi \ast \nu) \|_{L^2(G)}$. By the triangle inequality and a change of variables $x \mapsto sx$, we have

$$I \leq \sum_{s \in M / \Gamma} |h_s| (\int_{x \in G} |\varphi|^2 (x) |\psi \ast \nu(sx)|^2)^{1/2}.$$ 

By a change of variables, $\psi \ast \nu(sx) = \int_{y \in G} \psi(sy) \nu^*_y (x)$ with $\nu^*_y(x) := \nu(x^{-1}y)$. By the triangle inequality, $I \leq \int_{y \in G} \sum_{s \in M / \Gamma} |h_s| |\psi(sy)||\nu^*_y|_{L^2(G)}$. We unfold $\int_{y \in G} \sum_{s \in M / \Gamma} = \int_{y \in X} \sum_{s \in \Gamma \setminus M \gamma \in \Gamma}$, giving $I \leq \int_{y \in X} T^\alpha \Psi(y) |\varphi \ast \nu^*_y|_{L^2(G)}$. We conclude via Cauchy–Schwartz and the identity $\int_{y \in X} |\varphi \ast \nu^*_y|^2_{L^2(G)} = \| \nu \|^2_{L^2(Y)} |\varphi|^2_{L^2(X)}$. \hfill \Box

5. Representation-theoretic preliminaries

5.1. Generalities. Let $k$ be a non-archimedean local field with maximal order $\mathfrak{o}$, maximal ideal $p$, normalized valuation $\nu : k \to \mathbb{Z} \cup \{+\infty\}$, and $q := \# \mathfrak{o}/p$. Fix Haar measures $dx, d^x y$ on $k, k^x$ assigning volume one to maximal compact subgroups. Fix a nontrivial unramified additive character $\psi : k \to \mathbb{C}^{(1)}$. Set $G := \text{GL}_2(k)$.

5.2. Some notation and terminology. For $x \in k$ and $y_1, y_2 \in k^x$, set

$$n(x) := \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}, \quad n'(x) := \begin{pmatrix} 1 & 0 \\ x & 1 \end{pmatrix},$$

$$\text{diag}(y_1, y_2) := \begin{pmatrix} y_1 & 0 \\ 0 & y_2 \end{pmatrix}, \quad w := \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$$

and $a(y) := \text{diag}(y, 1)$, $z(y) := \text{diag}(y, y)$. Say that a vector $v$ in some $\text{GL}_2(k)$-module $\pi$ is supported on $m, m'$, for integers $m, m'$ with $m \leq m'$, if $v$ is invariant by $n(p^{-m})$ and $n'(p^m')$, and that $v$ has orientation $(\omega_1, \omega_2)$, for characters $\omega_1, \omega_2$ of $\mathfrak{o}^\times$, if $\pi(\text{diag}(y_1, y_2)v) = \omega_1(y_1)\omega_2(y_2)v$ for all $y_1, y_2 \in \mathfrak{o}^x$.

5.3. Principal series representations. For characters $\chi_1, \chi_2 : k^x \to \mathbb{C}^\times$, denote by $\pi = \chi_1 \boxtimes \chi_2$ the principal series representation of $G$ realized in its induced model as a space of smooth functions $\nu : G \to \mathbb{C}$ satisfying $\nu(n(x) \text{diag}(y_1, y_2)g) = |y_1/y_2|^{1/2} \chi_1(y_1)\chi_2(y_2)v(g)$ for all $x \in k$ and $y_1, y_2 \in k^x$ and $g \in G$. A sufficient condition for $\pi$ to be irreducible is that $c(\chi_1/\chi_2) \neq 0$. If $\chi_1, \chi_2$ are unitary, then $\pi$ is unitary; an invariant norm is given by $\| v \|^2 := \int_{x \in k} |\nu(n'(x))|^2 dx$. The logarithm of $c(\pi) = c(\chi_1) + c(\chi_2)$ and the central character is $\chi_\pi = \chi_1\chi_2$.

The following “line model” parametrization of $\pi$ shall be convenient: for suitable $f \in C^\infty_k$, define $v_f \in \pi$ by

$$v_f(g) := f(c/d) |\det(g)/d^2|^{1/2} \chi_1(\det(g)/d)\chi_2(d), \quad g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}. \quad (16)$$

If $\chi_1, \chi_2$ are unitary, then $\| v_f \|^2 = \int_k |f|^2$. 

5.4. **Generic representations.** Recall that an irreducible representation \( \sigma \) of \( G \) is generic if it is isomorphic to an irreducible subspace \( W(\sigma, \psi) \) of the space of smooth functions \( W : G \to \mathbb{C} \) satisfying \( W((xg))(g) = \psi(x)W(g) \) for all \( x, g \in k, G \); in that case, \( W(\sigma, \psi) \) is called the Whittaker model of \( \sigma \). It is known that every non-generic irreducible representation of \( G \) is one-dimensional.

For each \( W \in W(\sigma, \psi) \), denote also by \( W \) the function \( W : k^\times \to \mathbb{C} \) defined by \( W(y) := W(\alpha(y)) \). The space \( K(\sigma, \psi) \) of functions \( W : k^\times \to \mathbb{C} \) arising in this way from some \( W \in W(\sigma, \psi) \) is called the Kirillov model of \( \sigma \). It is known that \( K(\sigma, \psi) \supseteq C_c^\infty(k^\times) \).

An irreducible principal series representations \( \pi = \chi_1 \boxtimes \chi_2 \) is generic; the standard intertwining map from \( \pi \) to its \( \psi \)-Whittaker model \( W(\pi, \psi) \), denoted \( \pi \ni v \mapsto \mathcal{W}_v : GL_2(k) \to \mathbb{C} \), is given by \( \mathcal{W}_v(g) := \int_{x \in k} \nu(\nu n(x)g)\psi(-x)dx \). In general, this integral fails to converge absolutely and must instead be interpreted via analytic continuation, regularization, or as a limit of integrals taken over the compact subgroups \( p^{-n} \) of \( k \) as \( n \to \infty \) (see e.g. [7, p485]); we ignore such standard technicalities here.

5.5. **Newvector theory.** Recall Definition 20.

**Theorem 42** (Basic newvector theory). Let \( \pi \) be a generic irreducible representation of \( GL_2(k) \) and let \( m \leq m' \) be integers. Then the space of vectors in \( \pi \) supported on \( m..m' \) and with orientation \( (1, \chi_1|_{\mathfrak{o}^\times}) \) has dimension \( \max(0, 1 + |m - m'| - c(\pi)) \).

In particular, let \( \pi \) be any irreducible representation of \( GL_2(k) \) with ramified central character \( \chi_\pi \). Denote by \( V \) the space of vectors in \( \pi \) supported on \(-N_2..N_2\) with orientation \( (1, \chi_\pi|_{\mathfrak{o}^\times}) \). Then \( V = 0 \) unless \( \pi \) is generic, in which case \( \dim V = \max(0, 1 + c(\pi) - N) \).

**Proof.** For the first assertion, see [8]. The generic case of the second assertion follows from the first assertion, so suppose \( \pi \) is one-dimensional. Write \( \pi = \chi \circ \det \) for some \( \chi : k^\times \to \mathbb{C}^\times \). Since \( \chi_\pi \) is ramified, the characters \((1, \chi_\pi|_{\mathfrak{o}^\times}) \) and \((\chi|_{\mathfrak{o}^\times}, \chi_\pi|_{\mathfrak{o}^\times}) \) of \( \mathfrak{o}^\times \times \mathfrak{o}^\times \) are distinct, and so \( V = 0 \).

**Lemma 43.** Let \( \pi \) be an irreducible generic representation of \( GL_2(k) \) with ramified central character \( \chi_\pi \). Then \( c(\chi_\pi) \leq c(\pi) \) with equality precisely when \( \pi \) is isomorphic to an irreducible principal series representation \( \chi_1 \boxtimes \chi_2 \) for which at least one of the inducing characters \( \chi_1, \chi_2 \) is unramified.

**Proof.** This is well-known, see [39, Lemma 3.1] or [9, Proof of Prop 2].

**Lemma 44.** Let \( \pi = \chi_1 \boxtimes \chi_2 \) be an irreducible principal series representation of \( G \). Let \( v \in \pi \) be a newvector of some support \( m..m' \).

1. If \( \chi_1 \) is ramified and \( \chi_2 \) is ramified, then \( v = v_f \) as in (16) for \( f \) a character multiple of the characteristic function of an \( \mathfrak{o}^\times \)-coset, thus \( f = c\chi_1|_{\mathfrak{m}^n \mathfrak{o}^\times} \) for some \( c \in \mathbb{C} \), \( \chi : k^\times \to \mathbb{C}^\times \) and \( n \in \mathbb{Z} \).
2. If \( \chi_1 \) is unramified and \( \chi_2 \) is ramified, then \( v = v_f \) for \( f = c1_\mathfrak{a} \) for some scalar \( c \) and fractional \( \mathfrak{o} \)-ideal \( \mathfrak{a} \subset k \).

**Proof.** Both assertions are well-known in the special case \( m = 0 \) (see [33]) and follow inductively in general using that \( a(\varpi) \) bijectively maps newvectors of support \( m..m' \) to those of support \( m - 1..m' - 1 \).
5.6. Local Rankin–Selberg integrals. Let \( \pi \) be an irreducible unitary principal series representation of \( G := \text{GL}_2(k) \) and \( \sigma \) an irreducible generic unitary representation of \( \text{PGL}_2(k) \). We have the following special case of a theorem of D. Prasad:

**Theorem 45.** [29] The space \( \text{Hom}_G(\sigma \otimes \Pi \otimes \pi, \mathbb{C}) \), consisting of trilinear functionals \( \ell : \sigma \otimes \Pi \otimes \pi \to \mathbb{C} \) satisfying the diagonal invariance \( \ell(\sigma(g)v_1, \Pi(y)v_2, \pi(g)v_3) = \ell(v_1, v_2, v_3) \) for all \( g \in G \) and all vectors, is one-dimensional.

We may fix a nonzero element \( f_{RS} \in \text{Hom}_G(\sigma \otimes \Pi \otimes \pi, \mathbb{C}) \) as follows: Denote by \( Z \) the center of \( G \) and \( U := \{ n(x) : x \in k \} \). Equip the right \( G \)-space \( ZU \) with the Haar measure for which

\[
\int_{g \in ZU \setminus G} \phi(g) = \int_{g \in ZU} \int_{x \in k} \phi(ay)n'(x) \frac{dx}{|y|} dy
\]

for \( \phi \in C_c(ZU \setminus G) \) (see [22, §3.1.5]). Realize \( \pi \) in its induced model. For \( W_1 \in \mathcal{W}(\sigma, \psi), W_2 \in \mathcal{W}(\Pi, \psi) \) and \( v_3 \in \pi \), set \( \ell_{RS}(W_1, W_2, v_3) := \int_{ZU \setminus G} W_1 W_2 v_3 \) (see [22, §3.4.1]). The definition applies in particular when \( W_2 \) is the image \( W_\sigma \) of some \( \nu \in \pi \) under the intertwining from §5.4.

The trick encapsulated by the following lemma (a careful application of “non-archimedean integration by parts”) shall be exploited repeatedly in §6.3:

**Lemma 46** (Application of diagonal invariance). Let \( f \in C_c^\infty(k) \). Let \( U_1 \) be an open subgroup of \( \mathfrak{o}^\times \) for which \( \overline{f} \otimes f \) is \( U_1 \)-invariant in the sense that \( \overline{f}(ux)f(uy) = \overline{f}(x)f(y) \) for all \( u, x, y \in U_1 \). Let \( W \in \mathcal{W}(\sigma, \psi) \). Then

\[
\ell_{RS}(W_1, \overline{W}_{\psi f}, v_f) = \int_{x \in k} \frac{dt}{|t|} dx dy, \]

where \( F(x,y,t;W_1,U_1) := \mathbb{E}_{u \in U_1} W_1(a(y)n'(x/u)) \chi_1 \chi_2^{-1}(ut) \psi(ut) \) with \( \mathbb{E}_{u \in U_1} \) denoting an integral with respect to the probability Haar.

**Proof.** Set \( g := a(y)n'(x) = \begin{pmatrix} y & 1 \\ x & 1 \end{pmatrix} \). For \( t \in k \) one has \( wn(t)g = \begin{pmatrix} -x & -1 \\ y + tx & t \end{pmatrix} \), hence

\[
v_f(g) = f(x)|y|^{1/2} \chi_1(y),
\]
\[
\overline{v}(wn(t)g) = \overline{f}(x)|y+tx|/t|y/t|^{1/2} \chi_1^{-1}(y/t) \chi_2^{-1}(t),
\]
\[
v_f(g)\overline{W}_{\psi f}(g) = \int_{t \in k} v_f(g)\overline{v}(wn(t)g)\psi(-t) dt
\]
\[
= |y|f(x) \int_{t \in k} \overline{f} \left( x + \frac{y}{t} \right) \chi_1 \chi_2^{-1}(t) \psi(t) \frac{dt}{|t|}.
\]

Integrating against \( W_1(a(y)n'(x))|y|^{-1} dx dy \) gives that \( \ell_{RS}(W_1, \overline{W}_{\psi f}, v_f) \) equals

\[
\int_{x \in k} \frac{dt}{|t|} dx dy,
\]

To obtain the claimed formula, we apply for \( u \in U_1 \) the substitutions \( t \mapsto ut, x \mapsto x/u \), invoke the assumed \( U_1 \)-invariance of \( \overline{f} \otimes f \), and average over \( u \). \qed
5.7. Gauss sums. We shall repeatedly use the following without explicit mention:

**Lemma 47.** Let $U_1 \subseteq \sigma^\times$ be an open subgroup and $\omega$ a character of $\sigma^\times$. For $t \in k^\times$, set $H(t) := H(t, \omega, U_1) := E_{u \in U_1} \omega(ut) \psi(ut)$, where $E$ denotes integration with respect to the probability Haar.

1. For fixed $U_1$, one has $H(t) = 0$ unless $-\nu(t) = c(\omega) + O(1)$, in which case $H(t) \ll C(\omega)^{-1/2}$, with implied constants depending at most upon $U_1$.
2. Suppose $U_1 = \sigma^\times$ and $c(\omega) > 0$. Then $H(t) = 0$ unless $-\nu(t) = c(\omega)$, in which case $H(t)$ is independent of $t$ and has magnitude $|H(t)| = cC(\omega)^{-1/2}$ for some $c > 0$ depending only upon $k$.

**Proof.** For $U_1 = \sigma^\times$, these are standard assertions concerning Gauss sums. The standard proof adapts to the general case (compare with [22, 3.1.14]). \( \square \)

6. Local study of non-archimedean microlocal lifts

Recall Definition 21 and the statement of Lemma 22. Retain the notation of §5.

6.1. **Proof of Lemma 22:** determination of microlocal lifts. For any character $\chi : k^\times \to \mathbb{C}^\times$, the non-equivariant twisting isomorphism $\pi \to \pi' := \pi \otimes \chi$ induces non-equivariant linear isomorphisms

$$V := \{ \text{microlocal lifts in } \pi \text{ of orientation } (\omega_1, \omega_2) \}$$

$$\cong \{ \text{microlocal lifts in } \pi' \text{ of orientation } (\omega'_1, \omega'_2) \}$$

with $\omega'_i := \omega_i \cdot |\chi|_{\sigma^\times}$. We thereby reduce to verifying the conclusion in the special case $\omega_1 = 1$. Suppose $V \neq 0$. Write $\omega := \omega_2$. By the convention $N \geq 1$ of Definition 21, $\omega$ is ramified. The central character $\chi_\pi$ of $\pi$ restricts to $\omega$, hence is ramified; by Theorem 42, $\dim V = \max(0, 1 + c(\pi) - c(\chi_\pi))$, and so $V \neq 0$ only if $c(\pi) \geq c(\chi_\pi)$. By Lemma 43, the latter happens only if $c(\pi) = c(\chi_\pi)$ and $\pi$ has the indicated form, in which case $\dim V = 1$. The explicit description of $V$ now follows in general from (18).

6.2. Explicit formulas. Let $\pi := \chi_1 \boxtimes \chi_2$ and $\omega_1 := \chi_1|_{\sigma^\times}$ with $N := c(\omega_1/\omega_2) \geq 1$.

**Lemma 48.** Define $f_1, f_2 \in C^\infty(k)$ (as if in the “line model” of §5.3) by

$$f_1(x) := 1_p \cdot v_2(x), \quad f_2(x) := 1_p \cdot (1/x) \cdot (1/x) |\chi_1|^{-1} \chi_2(x)$$

and $v_1, v_2 \in \pi$ in the induced model on $g = \begin{pmatrix} * & x \\ c & d \end{pmatrix} \in \text{GL}_2(k)$ by

$$v_1(g) := v_{f_1}(g) = 1_p \cdot v_2(c/d) \left| \frac{\det g}{d^2} \right|^{1/2} \chi_1(\det(g)/d) \chi_2(d),$$

$$v_2(g) := v_{f_2}(g) = 1_p \cdot v_1(d/c) \left| \frac{\det g}{c^2} \right|^{1/2} \chi_1(\det(g)/c) \chi_2(c)$$

and $W_1, W_2 \in \pi$ in the Kirillov model $K(\pi, \psi)$ by\footnote{Recall that $\psi$ is assumed unramified.}

$$W_1(y) := 1_p \cdot \bar{\nu}_{\chi_1}(y) |y|^{1/2} \chi_1(y), \quad W_2(y) := 1_p \cdot \bar{\nu}_{\chi_2}(y) |y|^{1/2} \chi_2(y).$$

Then $v_1, W_1$ and $v_2, W_2$ are microlocal lifts of orientations $(\omega_1, \omega_2)$ and $(\omega_2, \omega_1)$, respectively.
Proof. The formulas for $W_1, v_1$ in the case $\chi_1 = 1$ and those for $W_2, v_2$ in the case $\chi_2 = 1$ follow from known formulas for standard newvectors [33]; the general case follows from the twisting isomorphisms (18).

6.3. Stationary phase analysis of local Rankin–Selberg integrals. In this section we apply stationary phase analysis to evaluate and estimate some local Rankin–Selberg integrals involving microlocal lifts and newvectors. We use these in §7 to prove Theorem 25 and Theorem 29. Retain the notation of §5.1. Let $\chi_1, \chi_2$ be unitary characters of $k^\times$ for which $N := c(\chi_1/\chi_2)$ is positive. Let $\pi = \chi_1 \boxplus \chi_2$ be the corresponding generic irreducible unitary principal series representation of $GL_2(k)$, realized in its induced model and equipped with the norm given in §5.3. Equip the complex-conjugate representation $\overline{\pi}$ with the compatible unitary structure. Define the intertwiner $\pi \ni v \mapsto W_v \in \mathcal{W}(\pi, \psi)$ as in §5.4. Let $\sigma$ be a generic irreducible unitary representation of $PGL_2(k)$, realized in its $\psi$-Whittaker model $\sigma = \mathcal{W}(\sigma, \psi)$.

Theorem 49. Let $v \in \pi$ be a microlocal lift of orientation $(\chi_1|_{\mathfrak{o}^\times}, \chi_2|_{\mathfrak{o}^\times})$, let $v' \in \pi$ be a generalized newvector, and let $W_1 \in \sigma$.

(I) If $N$ is large enough in terms of $W_1$, then

$$\ell_{RS}(W_1, \overline{W}_v, v) = cq^{-N/2}\|v\|^2 \int_{y \in k^\times} W_1(y) d^\times y$$

where $c := q^{N/2} \int_{t \in k^\times} \chi_1 \chi_2^{-1}(t)\psi(t) dt / |t| \approx 1$ is a complex scalar which is independent of $W_1$ and whose magnitude depends only upon $k$.

(II) One has $\ell_{RS}(W_1 \otimes \overline{W}_{v'} \otimes v') \ll q^{-N/2}\|v'\|^2$ with the implied constant depending at most upon $W_1$.

(III) Suppose that $\nu(2) = 0$, $\chi_2$ is unramified, $\|v'\| = \|v\|$, the support of $v'$ is $-N, N$, $\sigma$ is unramified, and $W_1 \in \sigma$ is spherical, so that $N = c(\chi_1) = c(\chi_2)$ and $c(\pi) = 2N$. Then $\ell_{RS}(W_1, \overline{W}_v, v) = \ell_{RS}(W_1, \overline{W}_{v'}, v')$.

The most difficult assertion is (II), which is used only to deduce the equidistribution of newvectors (Theorem 17). Assertion (III) serves only the purpose of illustration (cf. the discussion after Theorem 25). The other main results of this article (Theorems 29, 27) require only (I), whose proof is very short.

Proof of (I). Without loss of generality, let $v = v_f$ with $f(x) := 1_{\mathfrak{p}^N}(x)$. Because $N_2$ is large in enough in terms of $W_1$, we have whenever $f(x) \neq 0$ that $W_1(a(y)n'(x/u)) = W_1(y)$ for all $u \in o^\times$. Lemma 46 gives after the simplifications $f(x)f(x+y/t) = 1_{\mathfrak{p}^N}(x)1_{\mathfrak{p}^N}(y/t)$ and $1_{\mathfrak{p}^N}(x)F(x, y, t; W_1, o^\times) = 1_{\mathfrak{p}^N}(x)W_1(y)H(t)$ with $H(t) := \mathbb{E}_{\psi(u)} \chi_1 \chi_2^{-1}(ut)\psi(u)$ that

$$\ell_{RS}(W_1, \overline{W}_v, v) = \int_{y \in k^\times} W_1(y) \int_{x \in k^\times} 1_{\mathfrak{p}^N}(x) \int_{t \in k} 1_{\mathfrak{p}^N}(y/t)H(t) dt / |t| d^\times y.$$

We have $W_1(y)H(t) = 0$ unless $|t| \approx q^N$ and $|y| \ll 1$; because $N_2$ is large enough in terms of $W_1$, the factor $1_{\mathfrak{p}^N}(y/t) = 1$ is thus redundant. Since $\int_{x \in k} 1_{\mathfrak{p}^N}(x) dx = \int_k |f|^2 = \|v\|^2$, we obtain the required identity.

---

8The integral defining $c$ should be interpreted in the usual way as (for instance) a limit of integrals over increasing finite unions of $o^\times$-cosets.
Proof of (II). Suppose first that $\chi_1$ and $\chi_2$ are both ramified. In that case, Lemma 44 says that $v' = v_f$ with $f$ a character multiple of the characteristic function of some $\sigma^\times$ coset. In particular:

$$f$$ is supported on a coset of $\sigma^\times$, and $\overline{f} \otimes f$ is $\sigma^\times$-invariant. \hspace{2em} (22)

From the mod-center identity $a(y)n'(x) \equiv n(y/x)a(y/x^2)wn(1/x)$, we have

$$W_1(a(y)n'(x)) = \psi(y/x)W_1(a(y/x^2)wn(1/x)).$$ \hspace{2em} (23)

From (23) and standard bounds on Whittaker functions, we have \(^9\)

$$\sup_{x \in k} \int_{y \in k^\times} |W_1(a(y)n'(x))| d^\times y \ll 1.$$ \hspace{2em} (24)

By (23), there exists a fixed open subgroup $U_1 \subseteq \sigma^\times$ for which

$$W_1(a(y)n'(x/u)) = W_1(a(y)n'(x)) \times \begin{cases} 1 & \text{for } |x| \leq 1, \\ \psi((u-1)y/x) & \text{for } |x| \geq 1. \end{cases}$$ \hspace{2em} (25)

Without loss of generality, suppose $\int_1 |f|^2 = 1$. We apply Lemma 46, split the integral according as $|x| \leq 1$ or not, and appeal to (24) and (25); our task thereby reduces to showing with

$$H_1(t) := \mathbb{E}_{u \in U_1, \chi_1} \chi_1^{-1}(ut)\psi(ut),$$

$$H_2(t, y/x) := \psi(-y/x)\mathbb{E}_{u \in U_1, \chi_1} \chi_1^{-1}(ut)\psi(u(t+y/x))$$

that the quantities

$$I_1 := \sup_{y \in k^\times} \int_{t \in k^\times} \int_{x \in k; |x| \leq 1} |f(x)\overline{f}(x+y/t)H_1(t)| d^\times x dt d^\times y,$$

$$I_2 := \sup_{y \in k^\times} \int_{t \in k^\times} \int_{x \in k; |x| > 1} |f(x)\overline{f}(x+y/t)H_2(t, y/x)| d^\times x dt d^\times y$$

are $O(q^{-N/2})$. We have $H_1(t) = 0$ unless $|t| \asymp q^N$, in which case $H_1(t) \ll q^{-N/2}$; the set of such $t$ has $d^\times t$-volume $O(1)$, so an adequate estimate for $I_1$ follows from Cauchy–Schwartz applied to the $x$-integral. Similarly, $H_2(t, y/x) = 0$ unless $|t+y/x| \asymp q^N$, in which case $H_2(t, y/x) \ll q^{-N/2}$; the support condition on $f$ shows that $f(x)\overline{f}(x+y/t) = 0$ unless $|t+y/x| = |t|$, we may conclude once again by Cauchy–Schwartz.\(^10\)

We turn to the case that one of $\chi_1, \chi_2$ is unramified. By the assumption $c(\chi_1/\chi_2) \neq 0$, the other one is ramified. By symmetry, we may suppose that $\chi_1$ is unramified and $\chi_2$ is ramified. By Lemma 44, we may suppose without loss of generality that $v' = v_f$ for $f = 1_a$ with $a \subset k$ a fractional $\sigma$-ideal. Then $\overline{f} \otimes f$ is $\sigma^\times$-invariant. We split the integral over $x \in k$ as above, and the same argument works for the range $|x| \leq 1$. The remaining range contributes

$$I_3 := \int_{x \in k; |x| > 1} \int_{y \in k^\times} \int_{t \in k^\times} 1_a(x)1_a(x+y/t)H_3(t, y/x; x) dx d^\times y d^\times t$$ \hspace{2em} (26)

\(^9\)See [22, 3.2.3], and recall that $\sigma$ is assumed generic and unitary.

\(^10\) The estimate just derived is essentially sharp when $f$ is supported in a fixed open subset of $k^\times$, but can be substantially sharpened when $f$ is “unbalanced” in the sense that its support tends sufficiently rapidly with $N$ either to zero or infinity. The possibility of such sharpening is the simplest case of the “weak subconvexity” phenomenon identified in [26].
where
\[ H_3(t, y/x; x) := W_1(a(y/x^2)\omega n(1/x))E_{u \in U_1}\chi_1\chi_2^{-1}(ut)\psi(u(t + y/x)). \]

A bit more care is required than in the above argument, which gives now an upper bound of \( +\infty \); the problem is that the nonvanishing of \( H_3(t, y/x; x) \) no longer restricts \( t \) to a volume \( O(1) \) subset of \( k^\times \). We do better here by exploiting additional cancellation coming from the \( y \)-integral: Let \( C_1, C_2 \) be positive scalars, depending only upon \( W_1, U_1 \), so that
\[ H_3(t, y/x; x) \neq 0 \implies C_1q^N < |y/x + t| < C_2q^N. \] (27)

If \( |y/x| \geq C_2q^N \), then \( H_3(t, y/x; x) \neq 0 \) only if \( |t| = |y/x| \). If \( |y/x| \leq C_1q^N \), then \( H_3(t, y/x; x) \neq 0 \) only if \( C_1q^N < |t| < C_2q^N \). Arguing as above, we reduce to considering the range \( C_1q^N < |y/x| < C_2q^N \), in which \( H_3(t, y/x; x) \neq 0 \) only if \( |t| < C_2q^N \). The range \( C_1q^N \leq |t| < C_2q^N \) may be treated as before, so we reduce to showing that
\[ I_4 := \int_{x,y,t \in k, k^\times, k^\times} 1_a(x)1_a(x + y/t)H_3(t, y/x; x) \, dx \, dy \, dt = 0. \] (28)

Note that the conditions defining the integrand imply that \( |xt/y| < 1 \). There is an open subgroup \( U_2 \) of \( \sigma^\times \), depending only upon \( W_1, U_1 \), so that
\[ z \in U_2, |xt/y| < 1 \implies \frac{t + zy/x}{t + y/x} \in U_1, \] (29)
\[ |x| > 1, z \in U_2 \implies W_1(a(zy/x^2)\omega n(1/x)) = W_1(a(y/x^2)\omega n(1/x)), \] (30)
\[ |xt/y| < 1, z \in U_2 \implies 1_a(x + zy/t) = 1_a(x + y/t). \] (31)

For \( N \) large enough in terms of \( W_1, U_1 \) and hence \( U_2 \), we have
\[ |xt/y| < 1 \implies E_{z \in U_2}\chi_1^{-1}\chi_2(t + zy/x) = 0. \] (32)

In \( I_4 \), we substitute \( y \mapsto yz \) with \( z \in U_2 \) and average over \( z \); by (31) and (30), our task reduces to establishing for \( |xt/y| < 1 \) that
\[ E_{z \in U_2}E_{u \in U_1}\chi_1\chi_2^{-1}(ut)\psi(u(t + zy/x)) = 0, \]
which follows from (32) after the change of variables \( u \mapsto u(t + y/x)/(t + zy/x) \) suggested by (29). \hfill \Box

Proof of (III). By (I), our task reduces to showing that
\[ \ell_{RS}(W_1, \overline{\nu}, \nu') = cq^{-N/2}\|\nu'\|^2 \int_{y \in k^\times} W_1(y) \, dx \sqrt{y} \]
with the same scalar \( c \) as in (I). Suppose without loss of generality that \( \nu' = \nu_f \) with \( f := \chi_21_{\sigma^\times} \). Note that \( \overline{\nu} \otimes f \) is \( \sigma^\times \)-invariant. If \( f(x) \neq 0 \), then \( W_1(a(y)n'(x/u)) = W_1(y) \) for all \( u \in \sigma^\times \). Lemma 46 gives after the simplification \( f(x)F(x, y, t; W_1, \sigma^\times) = f(x)W_1(y)H(t) \) with \( H \) as in the proof of (I) that
\[ \ell_{RS}(W_1, \overline{\nu}, \nu') = \int_{y \in k^\times} \int_{x \in k} \int_{t \in k} W_1(y)f(x)(x + y/t)H(t) \, dt \, dx \, dy. \]

Because \( \nu(2) = 0 \), we have \( c(\chi_2) = c(\chi_1\chi_2^{-1}) = N \). Thus if \( W_1(y)f(x)H(t) \neq 0 \), then \( y, x, t \in \sigma, \sigma^\times, \sigma^{-N}\sigma^\times \) and so \( f(x)\overline{f}(x + y/t) = 1 \). From \( \int_{x \in k} 1_{\sigma^\times}(x) \, dx = \int_k |f|^2 = \|\nu'\|^2 \), we conclude. \hfill \Box
Remark 50. [22, 3.4.2] and Theorem 49(I) and [22, (3.25)] imply the following: Let \(v_2, v_3 \in \pi\) be microlocal lifts of the same orientation and \(v_1 \in \sigma\), realized in its Kirillov model \(K(\sigma, \psi)\). The formula \(\|v_1\|^2 := \int_{y \in k^\times} |v_1(y)|^2 d^x y\) is known to define an invariant norm on \(\sigma\). Suppose that \(N\) is large enough in terms of \(v_1\). Then
\[
\int_{g \in \mathbb{Z} \setminus G} \prod_{i=1,2,3} \langle \pi_i(g)v_i, v_i \rangle = cq^{-N}\|v_2\|^2\|v_3\|^2 \int_{y \in k^\times} \langle a(y)v_1, v_1 \rangle d^x y
\]
for some positive scalar \(c \approx 1\) depending only on \(k\). This identity solves the problem of producing a subconvexity-critical test vector for the local triple product period in the QUE case when the varying representation is principal series. It would be interesting to verify whether the supercuspidal case follows similarly using a modification of Definition 21 involving characters on an \(\varepsilon\)-neighborhood in \(GL_2(\sigma)\) of the points of a suitable non-split torus, where \(\varepsilon \approx C(\pi \otimes \pi)^{-1/4}\).

7. Completion of the proof

In this section, \(\varphi \in \pi \in A_0(X)\) traverses a sequence of \(L^2\)-normalized microlocal lifts on \(X\) of level \(N \to \infty\). Thus \(\varphi\) and \(\pi\), like most objects to be considered in this section, depend upon \(N\), but we omit this dependence from our notation. We use the abbreviations fixed to mean “independent of \(N\)” and eventually to mean “for large enough \(N\).” Asymptotic notation such as \(o(1)\) refers to the \(N \to \infty\) limit. Our aim is to verify the conclusions of Theorem 25 and Theorem 29.

As \(G\)-modules, \(\pi \cong \chi_1 \boxplus \chi_2\) for some unitary characters \(\chi_1, \chi_2\) of \(\mathbb{Q}_p^\times\) for which \(c(\chi_1/\chi_2) = N\).

Recall our simplifying assumption that \(R\) is a maximal order. This implies that for any irreducible \(\mathcal{H}\)-submodule \(\pi'\) of \(A(X)\), the vector space underlying \(\pi'\) is an irreducible admissible \(G\)-module. In other words, the local components at all places \(v \neq p\) are one-dimensional.

The function \(\varphi\) has unitary central character, so the measure \(\mu_\varphi\) is invariant by the center. Moreover, for each prime \(\ell \mid \text{disc}(B)\), the involution \(T_\ell\) acts on \(\pi\) with some eigenvalue \(\pm 1\), hence \(\mu_\varphi\) is \(T_\ell\)-invariant. The natural space of observables against which it suffices to test \(\mu_\varphi\) is thus
\[
A^+(X) := \left\{ \Psi \in A(X) : T_\ell \Psi = \Psi \text{ for } \ell \mid \text{disc}(B), \quad z \Psi = \Psi \text{ for } z \in Z := \text{center of } G \right\}.
\]

That space decomposes further as \(A^+(X) = (\oplus \chi \mathbb{C}(\chi \circ \text{det})) \oplus A^0_\chi(X)\) where

- \(\chi\) traverses the set of quadratic characters of the compact group \(\mathbb{Q}_p^\times / \mathbb{Z}[1/p]^\times\) satisfying \(\chi(\ell) = 1\) for \(\ell \mid \text{disc}(B)\), and
- \(A^0_\chi(X) := A^+(X) \cap A_0(X)\), which decomposes further as a countable direct sum \(A^0_\chi(X) = \bigoplus_{\sigma \in \mathbb{A}^+(X)\sigma}\) where we substitute \(A\) for \(A\) to denote “irreducible submodules of.”

Let \(\sigma \in A^+(X)\) be fixed. It is either one-dimensional and of the form \(\mathbb{C}(\chi \circ \text{det})\) for some \(\chi\) as above, or belongs to \(A^0_\chi(X)\) and is generic as a \(G\)-module. Denote by \(\ell : \sigma \otimes \pi \otimes \pi \to \mathbb{C}\) the \(G\)-invariant functional defined by integration over \(X\).

Lemma 51. Suppose \(\sigma\) is one-dimensional and \(\ell \neq 0\). Then \(\sigma\) is trivial eventually.

Proof. Write \(\sigma = \mathbb{C}(\chi \circ \text{det})\) for some quadratic character \(\chi\). By Schur’s lemma, \(\pi \cong \chi_1 \boxplus \chi_2\) is isomorphic as a \(G\)-module to \(\pi \otimes \chi \circ \text{det} \cong \chi_1 \chi \boxplus \chi_2 \chi\), which is known to happen only if either \(\chi_1 = \chi_1 \chi\), in which case \(\chi\) is trivial, or \(\chi_1 = \chi_2 \chi\),
in which case \( c(\chi) = c(\chi_1/\chi_2) = N \to \infty \), which does not happen because \( \chi \) is quadratic.\(^{11}\)

We now prove Theorem 25. It suffices to verify that the various assertions hold for fixed \( \Psi \in \sigma \in A^+(X) \). They are tautological if \( \sigma \) is trivial, so by Lemma 51, we reduce to the case that \( \sigma \in A^+_0(X) \) is generic. Fix an unramified non-trivial character \( \psi: \mathbb{Q}_p \to \mathbb{C}(1) \) and \( G \)-equivariant isometric isomorphisms \( \sigma \cong \mathcal{W}(\sigma, \psi), \pi \cong \chi_1 \otimes \chi_2 \). Denote by \( \ell_{RS}: \sigma \otimes \pi \otimes \pi \to \mathbb{C} \) the trilinear form defined in \( \S 5.6 \). By Theorem 45 and the nonvanishing of \( \ell_{RS} \), there exists a complex scalar \( \mathcal{L}^{1/2} \in \mathbb{C} \) so that

\[
\ell = \mathcal{L}^{1/2} \ell_{RS}.
\]

Theorem 49(I) implies that \( \ell_{RS}(\sigma(a(y))\Psi, \varphi, \varphi) = \ell_{RS}(\Psi, \varphi, \varphi) \) holds eventually for fixed \( y \in k^\times \); the required diagonal invariance then follows from (33). If \( p \neq 2 \) and \( \varphi' \) is an \( L^2 \)-normalized newvector of support \( -N, N \) and \( \Psi \in \sigma^K \) is spherical, then Theorem 49(III) gives \( \ell_{RS}(\Psi, \varphi, \varphi) = \ell_{RS}(\Psi, \varphi, \varphi') \) eventually; the lifting property then follows from (33). For the equidistribution application, we reduce by Lemma 51 and (33) and Theorem 49(II) to showing that \( \mathcal{L}^{1/2} = o(p^{N/2}) \) holds under the hypothesis that for each fixed \( \Psi_0 \in \sigma \), one has \( \ell(\Psi_0, \varphi, \varphi) = o(1) \). Let \( \Psi_0 \in \sigma \cong \mathcal{W}(\sigma, \psi) \) be given in the Kirillov model by the characteristic function of the unit group. By Theorem 49(I), \( \ell_{RS}(\Psi_0, \varphi, \varphi) \sim p^{-N/2} \) eventually, so our hypothesis and (33) give the required estimate for \( \mathcal{L}^{1/2} \).

We turn to the proof of Theorem 29. Our assumptions on \( \pi \) and \( \sigma \) imply that \( \sigma \in A^+_0(X) \) and that the adelizations of \( \sigma, \pi \) and \( \pi \) at each \( v \in S_B := \{\infty\} \cup \{\ell: \ell \mid \text{disc}(B)\} \) are one-dimensional and have trivial tensor product, hence that the product of their normalized matrix coefficients is one; by Ichino’s formula \([16]\) and \([22, 3.4.2]\), it follows that \( L \asymp |\mathcal{L}^{1/2}|^2 \), where \( L \) denotes the LHS of (5) and \( \mathcal{L}^{1/2} \) is as above (compare with Remark 50). By Theorem 27 and the argument of the previous paragraph, \( \mathcal{L}^{1/2} = o(p^{N/2}) \). Our goal is to show that \( L = o(C^{1/4}) \), where \( C := C(\sigma \times \pi \times \pi) \) is the global conductor; the contribution to \( C \) from \( v \in S_B \) is bounded, hence \( C \asymp C(\sigma_p \otimes \chi_1^{-1}\chi_2)\) and \( C(\sigma_p \otimes \chi_1^{-1}\chi_2) \sim C(\chi_1^{-1}\chi_2)^2 = p^{4N} \).

The known estimate \( \mathcal{L}^{1/2} = o(p^{N/2}) \) thus translates to the goal \( L = o(C^{1/4}) \), as required.
