Serum exosomal miR-377-3p inhibits retinal pigment epithelium proliferation and offers a biomarker for diabetic macular edema

Li Jiang, He Cao, Tingming Deng, Mingming Yang, Ting Meng, Huiqin Yang and Xiaoling Luo

Abstract

Objectives: Diabetic macular edema (DME) is a complication of diabetes mellitus that leads to diabetic retinopathy. Thus far, the role of serum exosomal microRNAs (miRNAs) in DME progression remains elusive. This study investigated serum exosomal miRNAs from patients with type 2 diabetes (T2D) and DME to identify miRNAs associated with expression of vascular endothelial growth factor (VEGF), a pivotal component in DME progression; it also evaluated the diagnostic values of these miRNAs for DME.

Methods: Serum was collected from patients with T2D who did (n = 20) and did not have DME (n = 24). Exosomes were isolated from serum and subjected to real-time polymerase chain reaction, western blotting, luciferase reporter, and miRNA profiling analyses.

Results: VEGF was significantly upregulated in ARPE-19 cells treated with exosomes from patients with T2D and DME, compared with exosomes from patients with T2D alone. Among the top 10 downregulated miRNAs identified during exosomal miRNA profiling, miR-377-3p inhibited the expression of VEGF. Luciferase reporter assays confirmed that miR-377-3p could directly regulate VEGF expression. Receiver operating characteristic analysis identified serum exosomal miR-377-3p as a potential biomarker for DME.

Conclusion: Serum exosomal miR-377-3p inhibits VEGF expression to suppress retinal pigment epithelium proliferation and offers a diagnostic biomarker for DME.
**Introduction**

The most common sight-threatening complication of diabetes is diabetic macular edema (DME), which causes diabetic retinopathy and vision loss through macular thickening due to increased levels of extracellular fluid derived from hyperpermeable retinal capillaries.\(^1\)\(^2\) Approximately 20% of patients with type 1 diabetes and 25% of patients with type 2 diabetes (T2D) developed DME within 10 years after the initial diagnosis.\(^1\)\(^3\)\(^4\) In China, the population with diabetes comprises 9.7% of people aged >20 years.\(^5\) Thus, there is an urgent need to understand the mechanism by which diabetes causes DME and identify potential biomarkers for DME, thereby providing insights for clinical treatment.

Exosomal microRNAs (miRNAs) have been identified as biomarkers in several diseases, such as hepatocellular carcinoma and osteosarcoma.\(^6\)\(^7\) However, the involvement of exosomal miRNAs in DME is unclear. Exosomes contain various components, such as lipids, proteins, and nucleic acids (e.g., mRNAs, miRNAs, and non-coding RNAs), which are mainly located in the exosomal lumen.\(^8\) Exosomes must interact with target cells to mediate their intended biological functions; for example, exosomal miRNAs degrade target proteins by directly silencing target mRNAs.\(^9\) Many cell types can release exosomes; these cells include immunocytes and retinal pigment epithelium (RPE). Under conditions of oxidative stress, vascular endothelial growth factor (VEGF)-overexpressing exosomes released from RPE can strongly promote angiogenesis in endothelial cells.\(^10\) Furthermore, exosomes isolated from human umbilical cord mesenchymal stem cells can freely enter breast cancer cells to downregulate the expression of VEGF, thus inhibiting angiogenesis and associated tumorigenesis,\(^11\) which demonstrates that exosomes can regulate VEGF expression. VEGF is mainly produced by RPE and plays a pivotal role in retinopathy;\(^12\) accordingly, VEGF is a critical target for the treatment of DME, but its regulation remains largely uncharacterized.

In this study, we investigated the serum exosomal miRNA profiles in patients with T2D, with and without DME, to identify miRNAs associated with VEGF expression. We also evaluated their potential value in the diagnosis of DME.

**Materials and methods**

**Serum collection**

Ten-milliliter samples of peripheral blood were collected from patients with T2D, with and without DME, using tubes containing coagulant (KJ1002Z, Kang-Jia Co. Ltd., Yuhuan, China). Only patients not receiving treatment for any condition were included in the study. All patient samples were obtained with written informed consent from participating patients. All experiments were conducted in accordance with the Helsinki Declaration. This study protocol was approved by the Ethical Committee...
Exosome extraction and quantification

Exosome extraction was conducted as previously described. Briefly, serum was obtained by centrifugation of blood samples at 900 $\times$ g for 10 minutes, then transferred to RNase-free tubes (Eppendorf, Hamburg, Germany) and stored at $-80^\circ$C until use. Exosome isolation from serum was performed using ExoQuick Exosome Precipitation Solution (EXOQ5A-1, System Biosciences, Palo Alto, CA, USA), in accordance with the manufacturer’s protocol. Specifically, serum samples were thawed and centrifuged at 3000 $\times$ g for 15 minutes to remove cell debris. Subsequently, 250 $\mu$L serum and 63 $\mu$L ExoQuick reagent were added to RNase-free tubes and samples were incubated at 4$^\circ$C for 12 hours. Finally, exosomes were collected by centrifugation at 1500 $\times$ g for 30 minutes. Exosome Capture & Quantification Kits (NBP2-49785, Novus Biologicals, Centennial, CO, USA) were used for exosome quantification, in accordance with the manufacturer’s instructions. The particle size and concentration were measured using a Nanoparticle Tracking Analysis 300 device (Malvern Instruments, Malvern, UK), in accordance with the manufacturer’s instructions.

Cell culture and treatment

ARPE-19 cells (Cobioer Biosciences, Nanjing, China) were cultured in Dulbecco’s modified Eagle’s medium/Nutrient mixture F12 (Thermo Fisher Scientific, Waltham, MA, USA) supplemented with 5 mM HEPES buffer, 7.5% NaHCO$_3$, 10% fetal bovine serum, and 1% penicillin/streptomycin; cells were maintained at 37°C and 5% CO$_2$.

To investigate the impacts of exosomes from different patient groups on VEGF expression, ARPE-19 cells were treated with 50 $\mu$g of exosomes. During repetitive exosome treatment, ARPE-19 cells were treated three times at 24-hour intervals. After treatments, ARPE-19 cells were harvested for real-time polymerase chain reaction and western blotting analysis.

To investigate the impacts of miRNAs on RPE proliferation, ARPE-19 cells (transfected as described in the next section) were seeded in 96-well plates ($1 \times 10^4$ cells/well) and incubated for 0, 1, 2, 3, 4, and 5 days at 37°C. Subsequently, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT; 5 mg/mL) was added at the indicated growth intervals and the cells were incubated for an additional 4-hour interval. Dimethyl sulfoxide (100 $\mu$L) was then added to each well. Finally, the absorbance was measured at 490 nm using a standard microplate reader.

Transfection with miR-377-3p and VEGF expression plasmids

ARPE-19 cells were seeded in six-well plates at $4 \times 10^5$ cells/well. When cells reached approximately 60% confluency, they were transfected with pCMV-miR-377-3p plasmid or pCMV negative control plasmid (OriGene, Rockville, MD, USA) using Lipofectamine 2000 (Thermo Fisher Scientific), in accordance with the manufacturer’s instructions. Stable clones were obtained via puromycin selection. For proliferation assays, cells were transiently transfected with VEGF plasmid (sc-29520-SH; Santa Cruz Biotechnology, Dallas, TX, USA) using Lipofectamine 2000.

Transmission electron microscopy

Isolated exosomes were re-suspended in 1 mL of phosphate-buffered saline; 3 $\mu$L of sample was then placed onto a
glow-discharged copper grid and covered with carbon film. After incubation for 30 s at room temperature, samples were stained with 3% uranyl acetate. Transmission electron microscopy observations were conducted using a Tecnai T120 microscope (Thermo Fisher Scientific). Whole exosomes in the images were measured to determine their size.

**RNA extraction and real-time polymerase chain reaction**

Total RNA was extracted using an RNA extraction kit (Sigma-Aldrich, St. Louis, MO, USA). cDNA was synthesized from extracted RNA using a High Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA, USA). Quantitative real-time polymerase chain reaction analyses were performed using cDNA and SYBR green dye (Applied Biosystems). Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) was used as the internal control and the $2^{-\Delta\Delta C_t}$ method was used for analysis. Primers were as follows: VEGF Forward: TTGCAGATGTGACAAGCCGA, VEGF Reverse: CGGCCGGTGTTGCTCTA; miR-377-3p Forward: AACTCGTCTCCAACGGGAA, miR-377-3p: Reverse: AAAGGCAACTTTTGTTT; and GAPDH Forward: TGACTTCAACAGCGACACCCA, GAPDH Reverse: CACCTGTGGCTGTAGCCAAA.

**Western blotting analysis**

Total protein was extracted from ARPE-19 cells by CytoBuster™ Protein Extraction Reagent (Novagen, Madison, WI, USA), then separated by 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis. Proteins in gels were transferred onto polyvinylidene difluoride membranes (Millipore, Burlington, MA, USA). Membranes were blocked with 1% bovine serum albumin, then incubated with primary antibody (described below) overnight at 4°C. Membranes were then incubated with horseradish peroxidase-conjugated anti-rabbit IgG secondary antibody (Abcam, Cambridge, MA, USA) at room temperature for 1 hour. Enhanced Chemiluminescence Reagent (Bio-Rad Laboratories, Hercules, CA, USA) was used to visualize immunoreactive bands. Primary antibodies were as follows: rabbit anti-VEGF (sc-7269; Santa Cruz Biotechnology), rabbit anti-GAPDH (5174; Cell Signaling Technology, Danvers, MA, USA), rabbit anti-CD9 (8457; Cell Signaling Technology), and rabbit anti-CD63 (sc-15363; Santa Cruz Biotechnology). Protein levels were quantified by ImageJ software (National Institutes of Health, Bethesda, MD, USA).

**Luciferase reporter assay**

VEGF 5'-untranslated region fragments of VEGF, containing the wild-type binding site of miR-377-3p or a corresponding mutant fragment, were cloned into a luciferase reporter vector (GeneCopoeia, Rockville, MD, USA). ARPE-19 cells were seeded in 24-well plates and co-transfected with wild-type or mutant VEGF 5'-untranslated region vector and miR-377-3p mimic or miR-negative control. After cells had been incubated for 48 hours, they were collected for the measurement of luciferase activity using the Luc-Pair™ Luciferase Assay Kit (GeneCopoeia).

**miRNA microarray analysis**

To investigate the miRNA expression profile, microarrays were performed as previously described. In brief, 100 ng of total RNA was used to construct miRNA libraries, which were then investigated with the Human microRNA Microarray Kit (version 3; Agilent Technologies, Santa Clara, CA, USA), in accordance with the
manufacturer’s instructions. Microarray data were processed for standardization, quality evaluation, and statistical analysis. The 75% quartile method was used for normalization. Analysis of miRNAs that regulate VEGF expression was performed using Targetscan Human 7.2 (www.targetscan.org/vert_72/).

**Statistical analysis**

Differences in miRNA expression levels between sample groups were determined using the Mann–Whitney U test. Comparisons of patient characteristics and gene expression levels (real-time polymerase chain reaction and western blotting analyses) were performed using Student’s t-test. Differences in cell viability between two groups were determined by repeated-measures analysis of variance. Data are presented as means ± standard deviations. GraphPad Prism, version 5 (GraphPad Software Inc., San Diego, CA, USA) was used for data analysis. Differences with P < 0.05 were considered statistically significant.

**Results**

**Exosomes from patients with T2D downregulate VEGF expression in ARPE-19 cells**

Exosomes were isolated from patients with T2D who did (n = 20) and did not have DME (n = 24). Clinical characteristics of all included patients are shown in Table 1; only central subfield thickness significantly differed between groups (P = 0.002). Exosomes isolated from different patients were subjected to nanoparticle tracking analysis, which revealed an acceptable size range (Figure 1a). CD9 and CD63 are markers of exosomes.\textsuperscript{15} Using western blotting, we confirmed expression of both CD9 and CD63 in exosomes randomly picked from six patients (Figure 1b). Transmission electron microscopy revealed that serum exosomes exhibited a typical saucer-like spheroid morphology (Figure 1c).

To determine the effects of exosomes on VEGF expression, ARPE-19 cells were treated with exosomes isolated from patients with T2D and DME or patients with T2D alone. Real-time polymerase chain reaction and western blotting analyses showed that VEGF expression was significantly greater in exosomes isolated from the serum of patients with T2D and DME than in exosomes isolated from the serum of patients with T2D alone (both analyses, P < 0.01; Figure 1d). These results implied that exosomes from patients with T2D and DME could not inhibit VEGF expression.

**miR-377-3p is downregulated in patients with DME**

miRNAs play a pivotal role in regulating protein expression.\textsuperscript{16} To determine the miRNA expression profiles in patients

| Characteristics                      | T2D alone (n = 20) | T2D and DME (n = 24) | P value |
|--------------------------------------|-------------------|----------------------|---------|
| Age (years)                          | 54 ± 9.2          | 58.1 ± 8.1           | 0.116   |
| Sex (male/female)                    | 13 (65%)/7 (35%)  | 17 (70.8%)/7 (29.2%) | 0.371   |

with DME, we isolated serum exosomes from 10 patients with T2D alone and nine patients with T2D and DME; the characteristics of these randomly selected patients are shown in Table 2. miRNA microarray analyses showed substantially altered miRNA expression levels between patients with T2D alone and those with T2D and DME (Figure 2a). Because of the pivotal role of VEGF in DME progression, we searched for miRNAs that regulate VEGF expression from among the top 10 miRNAs that were significantly downregulated (Figure 2b); only miR-377-3p was predicted to directly regulate VEGF expression, based on analysis using Targetscan Human 7.2 (www.targetscan.org/vert_72/).

Further analysis by real-time polymerase chain reaction revealed that miR-377-3p expression was significantly lower in exosomes from patients with T2D and DME than in exosomes from patients with T2D alone (P = 0.014; Figure 2c).

**miR-377-3p negatively regulates VEGF expression**

To confirm the relationship between miR-377-3p and VEGF, we conducted luciferase reporter assays. Transfection with a miR-377-3p mimic reduced luciferase activity associated with the wild-type VEGF promoter (P < 0.01), while transfection with a miR-377-3p mimic did not alter the
luciferase activity associated with the mutant VEGF promoter in ARPE-19 cells (Figure 3a); these results implied a direct interaction between miR-377-3p and VEGF mRNA. Consistent with this hypothesis, overexpression of miR-377-3p led to reduced VEGF expression at both mRNA and protein levels (P < 0.01; Table 2).

miR-377-3p negatively regulates VEGF expression. miR-377-3p–VEGF signaling regulates proliferation of ARPE-19 cells

VEGF is an important factor involved in regulating angiogenesis and vascular permeability. In a high glucose environment, VEGF overexpression leads to RPE proliferation, while promoting angiogenesis and vascular permeability, thereby causing DME. Here, we investigated the impact of miR-377-3p–VEGF signaling on RPE proliferation. Analysis using MTT revealed that miR-377-3p overexpression resulted in significant reduction of RPE proliferation (P < 0.01; Figure 4a,b). In contrast, VEGF restoration in miR-377-3p-overexpressing ARPE-19 cells resulted in significant enhancement of RPE proliferation (P < 0.05; Figure 4a,b). These observations suggested that miR-377-3p–VEGF signaling regulates RPE proliferation.

Serum exosomal miR-377-3p offers a potential diagnostic biomarker for DME

To determine the diagnostic value of serum exosomal miR-322-3p, receiver operating characteristic curve analysis was performed to distinguish patients with T2D and DME from patients with T2D: the area under the curve was 0.7781 (95% confidence interval = 0.6383–0.9180, P = 0.001; Figure 5).
These results indicated that serum exosomal miR-377-3p offers a potential diagnostic biomarker for DME.

**Discussion**

DME is a common complication of diabetes, which leads to substantial vision problems. The main cause of DME is the onset of macular thickening. VEGF overexpression plays a pivotal role in DME progression, but its mechanism and diagnostic role have remained elusive. Serum exosomal miRNAs have been identified as biomarkers of several diseases, although their value in DME has been unclear. In this study, we isolated serum exosomes from patients with T2D and DME, as well as patients with T2D alone. To determine the effects of exosomes from these patients on VEGF expression, we cocultured ARPE-19 cells with each type of exosomes. Importantly, VEGF expression was significantly upregulated in ARPE-19 cells cocultured with exosomes from patients with T2D and DME. We then compared miRNA profiles between exosomes from patients with T2D and exosomes from patients with T2D and DME, which revealed substantial differences. Analysis of the top 10 miRNAs downregulated in exosomes isolated from patients with T2D and DME revealed that miR-377-3p was likely to regulate VEGF expression; this prediction was confirmed by in vitro experiments, which showed that miR-377-3p could directly bind to VEGF and negatively regulate its expression. Proliferation assay analysis showed that miR-377-3p reduced RPE proliferation by inhibition of VEGF.

Previous studies have shown that miR-377-3p has an inhibitory effect on the development of other diseases; consistent
with the prior findings, our data suggest that miR-377-3p may broadly prevent disease progression. Additionally, we revealed the potential value of exosomal miR-377-3p as a diagnostic biomarker in DME, based on the findings of receiver operating characteristic analysis.

A notable limitation of our study was that it only included patients with T2D (with and without DME); thus, the role of miR-377-3p in the progression from type 1 diabetes to DME requires further investigation. Another limitation was that serum exosomal miR-377-3p could not be fully validated as a diagnostic biomarker for DME; moreover, the isolation of serum exosomes is difficult. Future investigations should focus on the clinical value of miR-377-3p in larger numbers of patients and methods to simplify the isolation of serum exosomes. In summary, our study demonstrated that miR-377-3p can negatively regulate VEGF expression; moreover, miR-377-3p offers a diagnostic biomarker for DME.

Author contributions
HC, TD, MY, TM, HY, LJ, and XL carried out the studies, participated in collecting data, conducted cell experiments, and drafted the manuscript. HC and TD performed miRNA microarray analysis. MY analyzed microarray data. TM and HY isolated exosomes from serum. All authors read and approved the final manuscript.

Declaration of conflicting interest
The authors declare that there is no conflict of interest.
