Keywords: the companied Harmonic oscillator potential and its inverse, the isotropic harmonic oscillator plus inverse quadratic potential, Noncommutative space and phase, Boopp’s shift method, Boopp’s shift method.

ABSTRACT. A novel study for the exact solvability of nonrelativistic quantum spectrum systems for companied Harmonic oscillator potential and its inverse (the isotropic harmonic oscillator plus inverse quadratic potential) is discussed used both Boopp’s shift method and standard perturbation theory in both noncommutativity two dimensional real space and phase (NC-2D: RSP), furthermore the exact corrections for the spectrum of studied potential was depended on two infinitesimals parameters \( \theta \) and \( \bar{\theta} \) which plays an opposite rolls, this permits us to introduce a new fixing gauge condition and we have also found the corresponding noncommutative anisotropic Hamiltonian.

1. INTRODUCTION

One of the important problems in relativistic and nonrelativistic quantum mechanics is to find exact solutions to the Dirac, Klein-Gordon and Schrödinger equations for spherical and non spherical potentials that are used in different fields of physics and materials sciences, in commutative and noncommutative spaces-phases at two and three dimensional spaces [1-37]. In particular, the fermionic particle with spin \( (1/2) \) interacted with proton and in other hand interacted with external field produced by Harmonic oscillator and its inverse under investigation [7]. The application of noncommutativity properties on physics fields satisfied by imposing one or two new commutators \( (e=\hbar=1) \) [19-37]:

\[
[x_i, x_j] = i\theta_{ij} \quad \text{and} \quad [\hat{p}_i, \hat{p}_j] = i\bar{\theta}_{ij}
\]

It’s important to notice that, the above two fundamental commutators are satisfied in particulars’ cases from the general star product between two arbitrary functions \( f(x) \) and \( g(x) \) in the first order of two parameters \( \theta \) and \( \bar{\theta}_{ij} \) as follow [19-37]:

\[
f(x)\ast g(x)=f(x)g(x)-\frac{1}{2}\theta^{ij}\langle \frac{\partial^2}{\partial x_i \partial x_j}f(x)\rangle \langle \frac{\partial^2}{\partial x_i \partial x_j}g(x)\rangle -\frac{1}{2}\bar{\theta}^{ij}\langle \frac{\partial^2}{\partial x_i \partial \bar{x}_j}f(x)\rangle \langle \frac{\partial^2}{\partial x_i \partial \bar{x}_j}g(x)\rangle
\]

The two parts are represent the effects of the noncommutativity of space and phase, respectively, the parameters \( \theta^{ij} \) and \( \bar{\theta}_{ij} \) are antisymmetric real matrixes. At (NC-ND: RSP), a Boopp's shift method can be used, instead of solving any quantum systems by using directly star product procedure:

\[
[x_i, x_j] = i\theta_{ij} \quad \text{and} \quad [\hat{p}_i, \hat{p}_j] = i\bar{\theta}_{ij}
\]

In present work, the star product replaced by usual product together with a Boopp's shift in (NC-2D: RSP) [26-35]:

\[
\tilde{x} = x - \frac{\theta}{2} p_x, \quad \tilde{y} = y + \frac{\theta}{2} p_x \\
\hat{p}_x = p_x + \frac{\bar{\theta}}{2} y \quad \text{and} \quad \hat{p}_y = p_x - \frac{\bar{\theta}}{2} x
\]

We can prove, that: \([\tilde{x}, \hat{y}]\), \([\hat{p}_x, \hat{p}_y]\), \(\Delta x \Delta y\) and \(\Delta p_x \Delta p_y\) are only non null two commutators and the two uncertainties, respectively.
\[
\begin{align*}
\left\{ [\dot{x}, \dot{y}] = i\theta, \quad \left[ \dot{p}_x, \dot{p}_y \right] = -i\theta \right. \\
\left. \Delta x \Delta y \approx \theta \quad \text{and} \quad \Delta p_x \Delta p_y \approx \theta \right.
\end{align*}
\]  \tag{5}

Here \( \theta = \theta^{12} \) and \( \theta = \theta^{12} \), it's worth to mention, that the above two uncertainties, can be deduced from the generalized incertitude relations to the special coordinates and impulsions in noncommutative \( N \) dimensional space and phase, respectively:

\[
\Delta x' \Delta x' \gtrsim \frac{1}{2} |\rho'| \quad \tag{6}
\]

And

\[
\Delta p' \Delta p' \gtrsim \frac{1}{2} |\bar{\rho}'| \quad \tag{7}
\]

The main aim of this paper is to present and study a companied Harmonic potential and its inverse (h.p.i) in (NC-2D RSP) to discover the new symmetries and a possibility to obtain another application to this potential in different fields. The rest of present search is organized as follows: In next section, we briefly review the Schrödinger equation with companied Harmonic potential and it’s inverse. The Section 3, reserved to derive the deformed Hamiltonians of the Schrödinger equation with companied (h.p.i) and by applying both Boopp's shift method and standard perturbation theory we find the quantum spectrum of the lowest excitations in (NC-2D RSP) for studied potential. Finally, the important found results and the conclusions are discussed in the four and last section.

2. REVIEW OF COMPAINED HARMONIC POTENTIAL AND ITS INVERSE IN ORDINARY TWO DIMENSIONAL SPACES

Let’s present a brief review of time independent Schrödinger equation for a fermionic particle like electron of rest mass \( m_0 \) and its energy \( E \) moving in companied (h.p.i) \[7\]:

\[
- \frac{1}{2m_0} \left( \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) + \frac{\partial^2}{\partial \phi^2} + a r^2 + b r \right) \Psi(r) = E \Psi(r) \quad \tag{8}
\]

Where \((a = \frac{1}{2} m_0 \omega^2, b)\) are both constants. In polar coordinates, the complete wave function \( \Psi(r) \) separated as follows:

\[
\Psi(r) = R_n(r) \Phi(\phi) \quad \tag{9}
\]

Where the radial function \( R_n(r) \) and the angular function \( \Phi(\phi) \) are satisfied the following two equations, in 2D space respectively \[7\]:

\[
\begin{align*}
\left( \frac{d^2}{dr^2} + \frac{1}{r} \frac{d}{dr} - \frac{\ell^2}{r^2} - 2m_0(E - V(r)) \right) R_n(r) &= 0 \\
\left( \ell^2 \phi''(\phi) + m_0 E \Phi_m(\phi) \right) &= 0
\end{align*}
\]

Here \( m \) denote to the orbital angular momentum quantum numbers, the standard solution of \( \Phi(\phi) \) given by:

\[
\Phi(\phi) = \frac{1}{\sqrt{2\pi}} \exp(\pm im\phi) \quad \tag{11}
\]

Using the following abbreviations \[7\]:

\[
v(\nu + 1) = m^2 + 2m_0b, \quad \mu^2 = 2m_0a \quad \text{and} \quad \epsilon^2 = 2m_0E
\]

Then, a radial function satisfied the following differential equation \[7\]:

\[
\left( \frac{d^2}{dr^2} + \frac{1}{r} \frac{d}{dr} - \frac{\nu(\nu + 1)}{r^2} - \mu^2 r^2 + \epsilon^2 \right) R_n(r) = 0
\]

\[
\tag{13}
\]

Winches accept the solution:

\[
R_n(r) = C_m \exp \left( - \frac{\mu^2}{2} r^2 \right) r^k r F_1(-n,k+1,r^2)
\]

\[
\tag{14}
\]

Where the function \( r F_1(-n,k+1,r^2) \) is given by \[6\]:

\[
\]
\[ i \hat{F}_i \left(-n, k+1, r^2\right) = \frac{m_l k}{(n+k\hbar)} L_{(n)}^{(k)} (r^2) \]  
(15)

And \( C_{nl} \) is the normalization constant, determined from the condition [7]:

\[ C_{nl} = \left(\frac{\sqrt{2} \mu^{l+1} k}{\Gamma(k+n+1)}\right)^{1/2} \frac{n(n+k\hbar)}{n!\hbar^2} \]  
(16)

The complete orthonormalization eigenfunctions and the energy eigenvalues respectively in two dimensional spaces [7]:

\[ \Psi(r, \phi) = \frac{1}{\sqrt{\pi M}} \left(\frac{m^2}{\hbar^2} + \frac{2 M b}{n}\right)^{1/4} \exp\left(-\frac{m^2}{\hbar^2} r^2\right) \exp\left(-\frac{2 M b}{n} r^2\right). \]  
(17)

3. TWO DIMENSIONAL NONCOMMUTATIVE REAL SPACE AND PHASE FOR COMPAINED HARMONIC POTENTIAL AND ITS INVERSE

In this section, we present some fundamental principles of Schrödinger equation in (NC-2D: RSP); applying the important 4-steps on the ordinary quantum Schrödinger equation [27-36]:

Ordinary 2D - Hamiltonian : \( \hat{H}(p_x, x) \)  
\[ \rightarrow \text{NC 2D - Hamiltonian} : \hat{H}(\hat{p}_x, \hat{x}) \]  
(18.1)

Ordinary complex wave function : \( \Psi(\hat{r}) \)  
\[ \rightarrow \text{NC complex wave function} : \Psi(\hat{r}) \]  
(18.2)

Ordinary energy : \( E \rightarrow \text{NC energy} : E_{nc-ih} \)  
(18.3)

And

Ordinary product : \( \rightarrow \)  
New star product acting on phase and space : *  
(18.4)

This implies the Schrödinger equation in both (NC-2D RSP) as:

\[ \hat{H}(\hat{p}_x, \hat{x}) * \Psi(\hat{r}) = E_{nc-ih} \Psi(\hat{r}) \]  
(19)

Now, we apply the Boopp’s shift method on the above equation to obtain, the reduced Schrödinger equation (without star products):

\[ \hat{H}(\hat{p}_x, \hat{x}) \Psi(\hat{r}) = E_{nc-ih} \Psi(\hat{r}) \]  
(20)

This is a translation of a Schrödinger equation for \( \hat{p}_x \) and \( \hat{x} \) with the same complex wave function \( \Psi(\hat{r}) \). As a direct result of the eq. (4), the two operators \( r^2 \) and \( \hat{p}^2 \) in (NC-2D RSP) can be written as follows [24-30]:

\[ \left\{ \begin{array}{l} \hat{p}^2 = p^2 - \theta z \\ \hat{p}^2 = p^2 + \theta z \end{array} \right. \quad \text{with} \quad L_z = x p_y - y p_x \]  
(21)

It’s important to notice that, the two obtained results in eq. (21) conserved the symmetry between \( \hat{p}_x \) and \( \hat{x} \) and the rolls of \( \theta \) and \( \bar{\theta} \) are inversed(\( \theta \approx -\bar{\theta} \)). Based, on the eq. (21), to obtain, after a straightforward calculation, the three important terms, which will be use to determine the companied (h.p.i.) in (NC-2D: RSP) as:

\[ \begin{array}{l} \hat{p}^2 = \frac{p^2}{2m_0} - \theta \frac{\theta}{2m_0} \frac{L_z}{L_z} \\ \frac{\theta}{2m_0} = \frac{\theta}{2m_0} + \theta \frac{L_z}{L_z} \end{array} \]  
(22)

From above relations, one can write the deformed operator \( V_{b,\bar{p}}(\hat{r}) \) for companied (h.p.i.) and the noncommutative kinetic term \( \frac{\hat{p}^2}{2m_0} \), respectively:
\[ V_{h.p.}(r) = \alpha r^2 + \beta r^4 \]
\[ \frac{\beta}{2m_0} = -\frac{1}{2m_0} \left( \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial}{\partial r} \right) + \frac{\partial^2}{\partial \theta^2} \right) \]

Which allow us to obtaining the global potential operator \( H_{h.p.}(r) \) for combined (h.p.i.) in both (NC-2D RSP) as:
\[
H_{h.p.}(r) = a \frac{r^2}{\rho^2} + \frac{b}{\rho^4} + \left( \frac{\partial}{\partial \rho} \left( \frac{\partial}{\partial r} \right) \right) L_z
\]

It’s clearly, that the two first terms are given the ordinary companied (h.p.i.) in 2D space, while the rest terms are proportional’s with two infinitesimals parameters \( (\theta \text{ and } \overline{\theta} ) \) and then gives the terms of perturbations \( H_{h.p.}(r) \) in (NC-2D RSP) as:
\[
H_{h.p.}(r) = \left( \theta \left( \frac{b}{\rho^4} - b \right) + \frac{\overline{\theta}}{2m_0} \right) L_z
\]

This can be writing to the equivalent form:
\[
H_{h.p.}(r) = \left( \theta \left( \frac{b}{\rho^4} - b \right) + \frac{\overline{\theta}}{2m_0} \right) \sqrt{L^2}
\]

We orient the spin to the (Oz) which allow us to write, the perturbative term \( H_{h.p.}(r) \) as follows:
\[
H_{h.p.}(r) = \left( \theta \left( \frac{b}{\rho^4} - b \right) + \frac{\overline{\theta}}{2m_0} \right) \left( \frac{J^2}{2L^2} - \frac{L^2}{2} - \frac{S^2}{2} \right)
\]

We have replaced \( \sqrt{L^2} \) by \( \frac{1}{2} \left( \frac{J^2}{L^2} - \frac{L^2}{2} \right) \), this operator traduce the coupling between spin and orbital momentum. Now we replace \( \Psi(r) \) by \( R_{nl}(r) \Phi(\phi) \) in eq. (22), after profound straightforward calculation, one can show that, the radial function \( R_{nl}(r) \) and the angular function \( \Phi(\phi) \) are satisfied the following two equations, in (NC-2D: RSP), respectively:
\[
\frac{d^2}{dr^2} + \frac{1}{r} \frac{d}{dr} - \frac{m^2}{r^2} - 2m_0 \left( E_{nc-\hat{a}} - b \frac{\partial}{\partial \rho} \frac{\partial}{\partial r} \left( \frac{b}{\rho^4} - a \right) + \frac{\overline{\theta}}{2m_0} \right) L_z \right) R_{nl}(r) = 0
\]

The set \( \{ H_{n2\rho(h.p.\hat{a})}, J^2, L^2, S^2 \text{ and } J_z \} \) forms a complete of conserved physics quantities and the eigen-values of the spin orbital coupling operator are \( k_\pm = \frac{1}{2} \left[ \frac{1}{2} \left( l + \frac{1}{2} + 1 \right) \pm \frac{3}{4} \right] \) corresponding:
\[
j = l + \frac{1}{2} \text{ (spin up)} \quad \text{and} \quad j = l - \frac{1}{2} \text{ (spin down)} \]

such that, one can form a diagonal \( (2 \times 2) \) matrix, with non null elements are \( \{ H_{n2\rho(h.p.\hat{a})} \} \) and \( \{ H_{n2\rho(h.p.\hat{a})} \} \) for companied Harmonic potential and its inverse in (NC-2D RSP) as:
\[
H_{n2\rho(h.p.\hat{a})} = -\frac{\Delta}{2m_0} + ar^2 + \frac{b}{\rho^4} + k_\pm \left( \theta \left( \frac{b}{\rho^4} - b \right) + \frac{\overline{\theta}}{2m_0} \right)
\]

if \( j = l + \frac{1}{2} \) spin up
\[
H_{n2\rho(h.p.\hat{a})} = -\frac{\Delta}{2m_0} + ar^2 + \frac{b}{\rho^4} - k_\pm \left( \theta \left( \frac{b}{\rho^4} - b \right) + \frac{\overline{\theta}}{2m_0} \right)
\]

if \( j = l - \frac{1}{2} \) spin down

The energies \( E_{n2\rho(h.p.\hat{a})} \) and \( E_{n2\rho(h.p.\hat{a})} \) of a particle fermionic with spin up and spin down are determined, respectively, for companied Harmonic potential and its inverse in (NC-2D: RSP) as:
\[
E_{n2\rho(h.p.\hat{a})} = E_{n\rho} + E_{n2\rho(h.p.\hat{a})}
E_{n2\rho(h.p.\hat{a})} = E_{n\rho} + E_{n2\rho(h.p.\hat{a})}
\]
Where $E_{u2(h.p.i.)}$ and $E_{d2(h.p.i.)}$ are the modifications to the energy levels, associate with spin up and spin down, respectively, at first order of two parameters $\theta$ and $\bar{\theta}$ obtained by applying the perturbation theory, as follows:

$$E_{u2(h.p.i.)} = 2k_+ \left( \theta T_{s(h.p.i.)} + \frac{\bar{\theta}}{2m_0} T_{p(h.p.i.)} \right)$$
$$E_{d2(h.p.i.)} = -2k_+ \left( \theta T_{s(h.p.i.)} + \frac{\bar{\theta}}{2m_0} T_{p(h.p.i.)} \right)$$

(31)

In above two equations $T_{s(h.p.i.)}$ and $T_{p(h.p.i.)}$ are given by:

$$T_{s(h.p.i.)} = \int_0^\infty \exp\left(- \frac{\mu}{2} r^2 \right) r^4 F \left(-n, k+1, r^2 \right) \left( \frac{b}{r} - \sigma r \right) dr$$
$$T_{p(h.p.i.)} = \int_0^\infty \exp\left(- \frac{\mu}{2} r^2 \right) r^4 F \left(-n, k+1, r^2 \right) \left( \frac{b}{r} + \sigma r \right) dr$$

(32)

Where $A = \left( \frac{2^{k-1}}{\Gamma(k+n+1)} \right) \left( \frac{n+1}{n} \right)$, the first part in eq. (34) can be equal the sum of two terms $T_{s(h.p.i.)}^1$ and $T_{s(h.p.i.)}^2$ as:

$$T_{s(h.p.i.)}^1 = \frac{\theta b}{\mu} \int_0^\infty \exp\left(- \mu r^2 \right) r^{4-1} \left[ F \left(-n, k+1, r^2 \right) \right] \frac{r^2}{2} dr$$
$$T_{s(h.p.i.)}^2 = -\frac{\theta b}{\mu} \int_0^\infty \exp\left(- \mu r^2 \right) r^{4+1} \left[ F \left(-n, k+1, r^2 \right) \right] \frac{r^2}{2} dr$$

(33)

It’s convenient to introduce a new variable $v = \mu r^2$ and then eq. (33) take the equivalent form:

$$T_{s(h.p.i.)}^1 = \frac{\theta b}{\mu} \int_0^\infty \exp\left(- v \right) F \left(-n, k+1, \frac{v}{\mu} \right) \frac{\sqrt{v}}{2} dv$$
$$T_{s(h.p.i.)}^2 = -\frac{\theta b}{\mu} \int_0^\infty \exp\left(- v \right) F \left(-n, k+1, \frac{v}{\mu} \right) \frac{\sqrt{v}}{2} dv$$

(34)

Applying the following special integration [38]:

$$\int_0^\infty v^{\alpha-1} \exp(-v) \left[ F\left(-n, k+1, v\right) \right]^2 dv = \frac{n! \Gamma(\alpha)}{\gamma(\gamma+1) (\gamma+n-1) \left( \frac{(n-k)(k+1-n)}{\mu} \right)^{\gamma+n-1} + \ldots}$$

(35)

Then, we can prove that first integral in equation (33) is:

$$\int_0^\infty \exp(-v) v^{4-1} \left[ F\left(-n, k+1, \frac{v}{\mu} \right) \right]^2 dv = B \left( 1 + \frac{(n-k+1)(k+1-n)}{\mu} + \ldots \right)$$

(36)

Where $B = \frac{n! \Gamma(k+1)}{(k+1) \Gamma(k+n+1)}$, the eq. (35) can be simplified to the form:

$$\int_0^\infty \exp(-v) v^{4-1} \left[ F\left(-n, k+1, \frac{v}{\mu} \right) \right]^2 dv = \frac{B(k+1)}{k+1}$$

(37)

And the second integral in equation (36) can be written as follow:

$$\int_0^\infty v^{4+1} \exp(-v) \left[ F\left(-n, k+1, \frac{v}{\mu} \right) \right]^2 dv = M \left\{ \frac{\mu(k+2)}{4(k+1)} \right\}$$

(38)

Where $M = \frac{1}{(k+1) \Gamma(k+2)}$, which allow us to get $T_{s(h.p.i.)}^1$ as follows:
The obtained factor: \( L_{\text{h.p.i.}}(n, k) \) winches represent the role of (NC-2D) space as:

\[
I_{\text{h.p.i.}}(n,k) = \frac{A_{2D}(2n + 1)}{2\mu^2 r^4} \left( \frac{nn!}{(n + k)!} \right)^2 \frac{n(n - 1)(n - 2)(n - 3)}{4(k + 2)}.
\]  

(40)

Now, if we replace \( F_1(-n, k + 1, r^2) \) by its values \( \frac{n!k!}{(k + n)!} L_n^k(r^2) \), the second part of the equation (34), can be written as:

\[
T_{\text{p(h.p.i.)}} = \frac{\mu!}{2(k + n)!} \int_0^{\infty} \exp(-\mu^2 r^2) r^{2k} L_n^k(r^2) dr
\]  

(41)

It’s necessary to introduce a new variable \( r^2 = x \) and then we rewriting \( T_{\text{p(h.p.i.)}} \) as have:

\[
T_{\text{p(h.p.i.)}} = \frac{A_{2D}}{2} \left( \frac{k!}{(k + n)!} \right)^2 \int_0^{\infty} \exp(-\mu^2 x) x^{k-1/2} L_n^k(x)^2 dx.
\]  

(42)

Now, we apply the integral \([7, 38]:\)

\[
\int_0^{\infty} x^2 \exp(-x) \left[ L_n^2(x) \right]^2 dx = \frac{\Gamma(A + B + 1)}{B!}
\]  

(43)

Which allow us to writing (NC-2D) phase contribution \( T_{\text{p(h.p.i.)}} \) as:

\[
T_{\text{p(h.p.i.)}} = \frac{A_{2D}}{2} \left( \frac{k!}{(k + n)!} \right)^2 \Gamma \left( k - \frac{1}{2} + n + 1 \right)
\]  

(44)

The modification to the energy levels, associate with spin up and spin down, at first order of \( \theta \) and \( \overline{\theta} \) for companied Harmonic potential and its inverse in both (NC-2D: RSP) are given by:

\[
E_{\text{up}(n, k)} = Ak \left( n \omega_{\text{up}} + \overline{\theta} \omega_{\text{up}} \right) \left( \frac{k!}{(k + n)!} \right)^2 \Gamma \left( k - \frac{1}{2} + n + 1 \right)
\]  

(45)

\[
E_{\text{down}(n, k)} = -Ak \left( n \omega_{\text{down}} + \overline{\theta} \omega_{\text{down}} \right) \left( \frac{k!}{(k + n)!} \right)^2 \Gamma \left( k - \frac{1}{2} + n + 1 \right)
\]  

The first two terms in above two equations are clearly determine the physics contributions of (NC-2D) space, while the second parts gives physics contributions of (NC-2D) phase, we conclude, from Eqs. (47) and (32) one can resume the total energy of electron with two polarisations spin up and down \( E_{\text{up}(h.p.i.)} \) and \( E_{\text{down}(h.p.i.)} \) corresponding \( (H_{\text{h.p.i.}})_{11} \) and \( (H_{\text{h.p.i.}})_{22} \), respectively for companied Harmonic potential and its inverse in (NC-2D: RSP) as:

\[
E_{\text{up}(n, k)} = \omega(2n + 1) + Ak \left( n \omega_{\text{up}} + \overline{\theta} \omega_{\text{up}} \right) \left( \frac{k!}{(k + n)!} \right)^2 \Gamma \left( k - \frac{1}{2} + n + 1 \right)
\]  

(46)

\[
E_{\text{down}(n, k)} = \omega(2n + 1) - Ak \left( n \omega_{\text{down}} + \overline{\theta} \omega_{\text{down}} \right) \left( \frac{k!}{(k + n)!} \right)^2 \Gamma \left( k - \frac{1}{2} + n + 1 \right)
\]  

Thus, the eigenvalues of energies are real’s and then the NC Hamiltonian is Hermitian for companied Harmonic potential and its inverse, in another hand it’s possible to writing it as follows:

\[
H_{\text{NC-}(h.p.i.)} = H_{\text{h.p.i.}} + H_{\text{so-}(h.p.i.)}
\]  

(47)

Where \( H_{\text{h.p.i.}} \) and \( H_{\text{so-}(h.p.i.)} \) are determined from, the following relation, respectively:

\[
H_{\text{h.p.i.}} = \begin{pmatrix}
-\frac{1}{2m_0} \left( \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2} \frac{\partial^2}{\partial \phi^2} \right) + ar^2 + b \frac{b}{r^2} \\
0 & 0 & 1 & 0
\end{pmatrix}
\]  

(48)

\[
H_{\text{so-}(h.p.i.)} = \begin{pmatrix}
\theta (b + \frac{\overline{\theta}}{2m_0} k_y) & 0 & 0 & 0 \\
0 & -k_z
\end{pmatrix}
\]
Here $H_{(h.p.i.)}$ represent an electron interacted exactly with companied Harmonic potential and its inverse in commutative 2D space while the matrix $H_{so-(h.p.i.)}$ denotes to the spin-orbital interaction. Furthermore, if we apply the three-following steps:

$$
\left( \partial \left( \frac{b}{r^2} - a \right) + \frac{\overline{\sigma}}{2m_0} \right) L_z \rightarrow \left( \chi \left( \frac{b}{r^2} - a \right) + \frac{\sigma}{2m_0} \right) \overline{BL} $$

$$\theta \rightarrow \chi B$$
$$\overline{\sigma} \rightarrow \sigma B$$

In addition to these steps, we choose the magnetic field $\overline{B} = B\overline{k}$, here $\chi$ and $\sigma$ are infinitesimal real proportional’s constants, the magnetic moment $\overline{\mu} = \frac{\hbar}{2}$ and $(-\overline{S\cdot B})$ denote to the ordinary Hamiltonian of Zeeman Effect, we obtains the modified new Hamiltonian for companied Harmonic potential and its inverse in (NC-2D: RSP) as:

$$H_{so-(h.p.i.)} = \left( \frac{b}{r^2} - a \right) + \frac{\sigma}{2m_0} \left( \overline{\sigma} \overline{j} - \overline{S\cdot B} \right)$$

The above operator represents two fundamentals interactions: the first one between spin and external uniform magnetic field (ordinary Zeeman Effect) while the other is a new coupling between the momentum of electron and external uniform magnetic field. As it’s mentioned previously, the two parameters $\theta$ and $\overline{\sigma}$ was played an opposite rolls which allow us to introduce the following gauge fixing condition of Maireche:

$$\overline{\sigma} = -\rho \theta$$

Here $\rho$ is a positive constant, our obtained spectrum, will be proportioned only to one infinitesimal parameter $\theta$ and positive constant.

### 4. RESULTS AND CONCLUSIONS

In present work, we solved the Schrödinger equation with the companied Harmonic oscillator potential and its inverse in both noncommutativity two dimensional of real space and phase, we used both Boopp’s shift method and standard perturbation theory to obtain the following resumed structure of the energy levels in a new symmetric, in two tables:

| Table: 1 |
|-----------|
| **The total energy in 2D space** | **NC space-spin orbit** | **NC phase-spin Orbit** |
| $E_{sn-(h.p.i.)} = \Theta Ak_+ \frac{L_{(h.p.i.)}(n,k)}{k+1}$ for spin up | $E_{sp+(h.p.i.)} = \frac{\hbar \Theta Ak_+}{2m_0} \frac{k+1}{\left( k+n \right)} \left( \frac{1}{2} + \frac{1}{2} n + 1 \right)$ | $E_{sp+(h.p.i.)} = \frac{\hbar \Theta Ak_+}{2m_0} \frac{k+1}{\left( k+n \right)} \left( \frac{1}{2} + \frac{1}{2} n + 1 \right)$ |
| $-Ak_+ \Theta L_{(h.p.i.)}(n,k)$ for spin down | $E_{sp-(h.p.i.)} = \frac{\hbar \Theta Ak_-}{2m_0} \frac{k+1}{\left( k+n \right)} \left( \frac{1}{2} + \frac{1}{2} n + 1 \right)$ | $E_{sp-(h.p.i.)} = \frac{\hbar \Theta Ak_-}{2m_0} \frac{k+1}{\left( k+n \right)} \left( \frac{1}{2} + \frac{1}{2} n + 1 \right)$ |
Thus, the obtained global full spectrum for companied $E_{\text{gndh.p.i.}}$ (for spin up) and $E_{\text{gndh.p.i.}}$ (for spin down) for Harmonic oscillator potential and its inverse:

$$E_{\text{gndh.p.i.}} = \alpha(2n + k + 1) + A\theta \left( \frac{2k + 1}{2} \right) \left( \frac{2(k + n)!}{2} \right) (k + m)$$

: for spin up

$$E_{\text{gndh.p.i.}} = \alpha(2n + k + 1) + A\theta \left( \frac{2k + 1}{2} \right) \left( \frac{2(k + n)!}{2} \right) (k + m)$$

: for spin down

And the corresponding formed noncommutative diagonal Hamiltonian for studied potential in (NC-2D: RSP) with elements $(H_{nc(h.p.i.)})_{11}$, $(H_{nc(h.p.i.)})_{22}$, $(H_{nc(h.p.i.)})_{12}$ and $(H_{nc(h.p.i.)})_{21}$:

$$\begin{align*}
(H_{nc(h.p.i.)})_{11} &= \left[ -\frac{\hbar^2}{2m} + \alpha^2 + \frac{\hbar}{\e} \right] + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right) + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right) + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right) + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right)
\end{align*}$$

$$\begin{align*}
(H_{nc(h.p.i.)})_{22} &= \left[ -\frac{\hbar^2}{2m} + \alpha^2 + \frac{\hbar}{\e} \right] + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right) + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right) + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right) + \frac{\hbar}{\e} \left( \frac{b}{\e} - a \right)
\end{align*}$$

$$\begin{align*}
(H_{nc(h.p.i.)})_{12} &= (H_{nc(h.p.i.)})_{21} = 0
\end{align*}$$

Which allow us to obtaining the effect of the operators $(H_{nc(h.p.i.)})_{11}$ and $(H_{nc(h.p.i.)})_{22}$ on the complex wave function $\Psi(r, \phi)$ as:

$$\begin{align*}
(H_{nc(h.p.i.)})_{11} \Psi(r, \phi) &= E_{\text{gndh.p.i.}} \Psi(r, \phi) \\
(H_{nc(h.p.i.)})_{22} \Psi(r, \phi) &= E_{\text{gndh.p.i.}} \Psi(r, \phi)
\end{align*}$$

Thus, we can deduce that, the new found symmetries capable of describing many fields like the modified Zeeman Effect, spin orbital interaction and some other applications in different types of materials science.
