dopaminergic medication. The second objective was to explore the relationship between frequency of SoP experiences and dopaminergic drug, drug dosage and length of drug exposure. The experimental hypothesis was that SoP symptoms in PD would present more frequently in patients treated longer with higher dopaminergic drug doses.

**Background.** PD is a debilitating neurodegenerative disorder. Psychiatric symptoms are common and associated with impaired quality of life and higher treatment costs. PD psychosis often starts with ‘minor hallucinations’, the most common being a false ‘sense of presence’ (SoP), the vivid sensation that someone else is nearby when nobody is there. SoP symptoms typically do not cause significant distress but may act as a prognostic marker for future severe psychosis and may prompt alteration of treatment or reduction in dopaminergic drug dosage. This study aimed to extend prior research by characterizing SoP further and investigating the link with dopaminergic medication.

**Method.** This was a retrospective, cross-sectional study. Twenty-one patients diagnosed with PD completed a questionnaire to identify presence of SoP symptoms, duration of symptoms, timing of onset related to dopaminergic treatment and the frequency of symptoms in relation to current levodopa equivalent dose (LED). Descriptive frequencies were compared using a two-tailed t-test. Multiple regression analysis was conducted to assess the relationship between frequency of SP experiences, levodopa equivalent dose and length of drug exposure.

**Result.** Sixteen of twenty-one patients reported experiencing SoP symptoms. Patients who had not experienced SoP symptoms had a significantly lower LED than those who had experienced these symptoms. There were no other significant differences between the groups. No statistical significance was shown on regression analysis; however our study was not adequately powered for the regression analysis as the number of participants was too low.

**Conclusion.** This study confirms that SoP symptoms are common among patients with PD and supports a correlation between the total daily equivalent dose of levodopa and SoP symptoms. It does not provide evidence for a temporal relationship between onset of SoP symptoms and duration of dopaminergic treatment. The study was insufficiently powered and a larger study is required to investigate further.

**A two-year mirror-image study of the effect of treatment with paliperidone and aripiprazole long-acting injections on need for inpatient care and home treatment intervention**

Shay-Anne Pantall1*, Joseph Pilsbury2, Le Gan2 and Lisa Brownell1

1Birmingham and Solihull Mental Health NHS Foundation Trust and
2University of Birmingham

doi: 10.1192/bjo.2021.746

**Aims.** This Research aims to identify factors reported by recent and current trainees in choosing Child & Adolescent (C&A) Psychiatry for their higher training/career path. The hypothesis is that via thematic analysis prominent factors will emerge to inform future recruitment and retention.

**Background.** The need to attract more doctors into Psychiatry has been identified by NHS, Royal College of Psychiatrists and the Media; Health Education England figures show core psychiatry had lowest fill rates of any specialty in 2016,17 &18. Some subspecialties experience particular difficulties e.g. C&A. Royal College of Psychiatry analysis of workforce in March 2018 showed the numbers of C&A psychiatrists of all grades have fallen by 6.3% in four years and for consultants alone the decrease was 6.9% over the same period.

However, very little research has been completed investigating why trainees might choose C&A Psychiatry with a literature search revealing only one report of C&A trainees views in the UK in 2006.

**Method.** A qualitative design was chosen to provide insight into the factors affecting participants in choosing their career.

The theoretical framework supporting the study relates to capturing experience via a case study approach, aiming to explore reported issues in a real life context and considering similarities in the cases to inform future recruitment.

The Research was approved by The Health Research Authority and local Research & Development departments.

Purposeful sampling was used with voluntary participation following informed consent and non-identifiable demographic data were collected and analysed quantitatively.

Semi-structured interviews to saturation were conducted with fourteen (N = 14) participants asked questions exploring their...
subspecialty choice. Responses were recorded and transcribed verbatim prior to thematic analysis, including triangulation via a co-coding process to check areas were not over-represented and/or subject to researcher thoughts and possible unconscious biases.

**Result.** Semi-structured interviews included all North-East C&A trainees and 3 recently qualified Consultants.

Demographics results included 5 male and 6 female participants and 6 non-UK graduates. Emergent themes were analysed into key findings including:

- interest in children/specialty
- specialty experience
- supportive supervisors/team
- work-life balance
- opportunity to impact/intervene early.

Limitations include study of a single geographical area and possible researcher bias.

**Conclusion.** This Research provides novel findings re factors influencing career choice of C&A Psychiatry to inform future recruitment and retention. Clear themes have emerged re important recruitment/retention factors and the study highlights need for more research to investigate reasons why C&A is not chosen.

**The feasibility and acceptability of a peer-support group for mental health in Filipino prisons**

Bethany Platford

Nuffield Centre, Faculty of International Health and Development, School of Medicine, University of Leeds

doi: 10.1192/bjo.2021.747

**Aims.** To assess the feasibility and acceptability of implementing and facilitating a peer-support group for mental health in Filipino prisons.

**Objectives.** To identify the logistical issues faced in implementing and facilitating healthcare in Filipino Prisons

To explore attitudes of potential participants towards the implementation of a peer-support group for mental health in the prisons

To provide logical recommendations from my findings to inform future mental health support for prisoners in the Philippines

**Method.** Ethical approval was granted by the University of Leeds prior to data collection. In-country ethical approval was granted through my host Dr Rachael Pickering. Data collection occurred through observations and semi-structured interviews. Participants recruited included six secure-environment healthcare workers, eight prisoners and six ex-prisoners. Both prisoners and ex-prisoners were identified through gatekeepers and informed consent was gained. Interviews were transcribed before coding and themes identified.

**Result.** Feasibility: Bureaucracy and corruption were the main barriers to the potential successful implementation of a peer-support group, which were emergent themes. Space, time and staff were all themes identified that may help facilitate the group.

**Conclusion.** The findings highlighted many barriers but with perseverence and local cultural competence this peer-support group could be feasible and be accepted in Filipino prisons. It will be reducing a high unmet need for mental health services in these prisons and if ran successfully with positive effects, will be an example for other prisons across the Philippines and other low-middle income countries.

**Towards peak experience - exploring the influence of wilderness on conscious awareness**

Oli Purnell

Swansea University Medical School

doi: 10.1192/bjo.2021.748

**Aims.** This study examines what effect wilderness has on our conscious awareness, and by extension of that meta-cognition; our physical, mental and spiritual health. It reviews available scientific and artistic literature and integrates this with interviews in order to generate original grounded theory. It was found that intensity of wilderness experience varied proportionally with four mediators; Challenge, Immersion, Beauty and Time. With these maximised, experiences broadly within four themes occurred; Increased Awareness, Confidence, Perspective and Connectedness. When sufficiently intense, these four experiences amalgamated to elicit what Maslow described as 'Peak Experience'. As such, this thesis unexpectedly provides a pragmatic recipie towards peak experience, and a map of one's potential psychological journey, in the context of wilderness.

**Aims.** This observational study aims to describe the course of the admission and clinical characteristics of admissions to the PICUs in the Phoenix Care Centre, Dublin, Ireland. The authors hypothesised that the length of stay (LOS) would be shorter in male patients as compared to females.
