The effect of a siamese pumpkin and tuna-based powder (CHAGURO) diet in improving chol/HDL ratios in prediabetes individuals with dyslipidemia: a randomised trial

Abstract

**Background:** The study aimed to examine the effect of administering CHAGURO (a product of the combination of siamese pumpkin and tuna-based powder) on the lipid profile in prediabetes individuals with dyslipidemia.

**Methods:** The experimental trial was conducted with two intervention groups, with each group receiving a dose of 7.5g/70kg body weight (BW)/day (low dose) and 15g/70kg BW/day (high dose) for 60 days. Respondents in each group ranged in age from 30 to 60 years old. Prediabetes was defined as fasting blood sugar levels of 100-125 mg/dL, while cholesterol levels of 200 mg/dL was considered dyslipidemia. The mean baseline HbA1c level for all subjects was 5.5%. Respondents were randomized into intervention groups using simple randomization. Pre-test and post-test measurements were performed for body mass index (BMI), physical activity (using IPAQ-SF), hemoglobin A1c (HbA1c), lipid profile, blood pressure, and food intake (using SQ-FFQ). Statistical analyses performed included descriptive tests, independent and paired T-tests, and analysis of variance (ANOVA).

**Results:** Compared to the baseline, HbA1c, total cholesterol, low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and triglycerides in the two groups did not improve significantly by 60 days. For lipid variables, a significant
improvement in the cholesterol/high-density lipoprotein (chol/HDL) ratios were observed when compared against the baseline for the two groups. When comparing the changes between groups, 7.5 g of CHAGURO showed a larger improvement in HDL-C (mean differences: 1.86 mg/dL; 95% CI: -0.86-4.59), compared to 15 g of CHAGURO (mean differences: -3.62 mg/dL; 95% CI: -7.53-0.28). A significant (p<0.05) decrease in the chol/HDL ratio was observed in the 7.5 g CHAGURO group (mean differences: -0.20 mg/dL; 95% CI: -0.39-(-0.01)).

**Conclusions:** CHAGURO can be a functional food alternative to improve the condition of prediabetes people with dyslipidemia.

**Trial registration:** Dr. Sardjito General Hospital (KE/FK/0951/EC/2020), 27/08/2020

Functional Food, Siamese Pumpkin, Tuna, HbA1c, HDL-C, Chol/HDL Ratio, Prediabetes, Dyslipidemia
Introduction
Prediabetes is a condition that initiates the incidence of diabetes mellitus (DM), and its prevalence continues to increase.1 This condition increases the risk of type 2 DM by about 3-10 times, and other chronic diseases such as cardiovascular disease by 1.5 times, compared to healthy people.2 In addition, cardiovascular disease due to atherosclerosis of the walls of blood vessels and thrombosis is one of the leading causes of death in Indonesia.3 One of the main risk factors is a degenerative disease, such as hypertension, DM or dyslipidemia. Cardiovascular diseases, especially dyslipidemia and type 2 DM, are diseases whose risk factors increase with prediabetes.2 Nevertheless, prediabetes is a condition that can be managed by changing lifestyle, losing weight, regulating diet, and doing regular exercise.2

Treatment of prediabetes and diabetes using plant extracts (herbal medicine) and functional foods has been widely used since ancient times in various countries, one such plant is the siamese pumpkin (Sechium edule (Jacq.)).4 Experimental animal studies have been conducted extensively and the results support the positive effects of the siamese pumpkin extract on cardiovascular and glucose metabolism.5 The siamese pumpkin is a natural ingredient that has antioxidant, antimicrobial, diuretic, antihypertensive and hypcholeoleptensive effects, as well as hypoglycemic effects.6 Additionally, siamese pumpkin has cardioprotective effects that can help in the prevention and treatment of dyslipidemia, and can potentially be processed into several food products that have more economic value.5

In addition to siamese pumpkin, foods high in omega 3 fatty acids or eicosapentaenoic acid (EPA) and decosahexaenoic acid (DHA), such as tuna (Thunnus sp.) can also prevent atherosclerosis and even reduce the risk of obesity and other non-communicable diseases.7 Tuna is a good source of protein and omega 3 fatty acids that are good for heart health and help improve the lipid profile.8 In addition, omega 3 fatty acids affect glucose metabolism by changing cell membrane function, enzyme activity, insulin signals, and gene expression.8

It can be concluded that the combination of siamese pumpkin and tuna has potential nutritional content with protective against cardiovascular disease and type 2 DM. Therefore, this study tried to innovate both ingredients into functional foods in the form of powder as a diet for people with prediabetes and dyslipidemia. The study aimed to examine the effect of administering CHAGURO (a product name of a combination between siamese pumpkin and tuna-based powder) on serum levels of hemoglobin A1c (HbA1c), lipid profile, blood pressure, and food intake using SQ-FFQ. Statistical analyzes performed included descriptive tests, independent and paired T-tests, and analysis of variance (ANOVA).4

Methods
Siamese pumpkin and tuna-based powder (CHAGURO) product preparation
The formulation used is the formulation selected (best) based on the analysis of macronutrients, micronutrients, and organoleptic substances that have been published in the journal of the Ministry of Health of the Republic of Indonesia.9-11 Here are the formulations:

1. Processing details

CHAGURO products are made from tuna and siamese pumpkins on the market, thus the basic ingredients are easy to find. Tuna aged 2-3 years with an average weight of 2.5 kg was used. The young siamese pumpkin was chosen because they tend to have a sweeter taste than the old one. The process of making CHAGURO products started with tuna that was cleaned of blood, thorns, head, gills, other body parts, and dirt. The tuna meat was steamed until cooked for about 25 minutes. Next, the tuna meat was mashed until it formed flakes.

The finely shredded siamese pumpkin is placed in the oven at 55 °C for 4 hours. Tuna and pumpkin that have dried and formed flakes are mixed in one container with a ratio of 3:1.7 The selection of tuna and pumpkin ratio was based on
research done in mice. The study showed that a 3:1 ratio of tuna and pumpkin could have the best effect on HbA1c, triglycerides, HDL, low-density lipoprotein (LDL), and cholesterol levels in diabetic and dyslipidemia mice compared to other formulas.\textsuperscript{12} The 3:1 formula was the most preferred or likely formula chosen by 57 semi-trained panelists based on organoleptic tests.

2. Results of micronutrient, and organoleptic siamese pumpkin and tuna-based powder products (CHAGURO)

The results of the macronutrient tests in 100g of products showed that the selected CHAGURO contained Calories (kcal): 373.32 ± 0.31; Protein (g): 66.98 ± 0.06; Fat (g): 8.07 ± 0.01; Carbohydrate (g): 19.42 ± 0.10; Crude fiber (g): 7.73 ± 0.02; Ash (%): 5.53 ± 0.16; Calcium (mg): 146.14 ± 3.40; Magnesium (mg): 116.74 ± 0.55; Manganese (mg): 4.70 ± 0.07 and Zinc (mg): 1.59 ± 0.01. The levels of macronutrients and micronutrients in the CHAGURO products are in accordance with the standard SNI Abon (shredded fish) 01-3707-1995.\textsuperscript{11}

Study design

The formulation of selected CHAGURO products were tested for effects through experimental intervention tests, involving respondents who passed the screening and have received ethical approval from The Medical and Health Research Ethics Committee (MHREC), Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada - Dr. Sardjito General Hospital, under trial protocol register No.KE/FK/0951/EC/2020 (August 27, 2020).\textsuperscript{12} Based on the calculation of samples using the formula designed by Lwanga & Lameshow,\textsuperscript{13} which was corrected with an attrition rate of 20%, samples for each group of 29 and 32 respondents were determined.

The study was used a clustered quasi-experimental design. This experimental test was conducted with two intervention groups (see Figure 1), where each group received a different dose of 7.5 g/70 kg body weight (BW)/day (low dose or LD) and 15 g/70 kg BW/day (high dose or HD) for 60 days. Respondents were divided into intervention groups using simple randomization. Before and after the intervention, a pre-test and post-test was performed that included a HbA1c examination, lipid profile, blood pressure, food intake using the SQ-FFQ (Semi Quantitative-Food Frequency Questionnaire) interview, body mass index (BMI, referring to the Asia Pacific), and physical activity based on the duration of time respondents used to move every 7 days. Physical activity data were measured using the IPAQ-SF (International Physical Activity Questionnaires-Short Form). Furthermore, the intervention period of the administration of the

CHAGURO product runs, according to the group dose, for 60 days. During the intervention, blood pressure and BMI data were before and after the study, starting from August to October 2021. Statistical analysis includes descriptive tests, independent and paired T tests, as well as ANOVA.

All respondents were made aware of the research activities and signed an informed consent form. The inclusion criteria in this study (Figure 1) included the following: the respondents were over 30 years of age and less than 60 years of age, had a fasting blood sugar of 100-125 mg/dL and cholesterol of 200 mg/dL based on rapid tests, and domiciled in the Sleman Regency, Yogyakarta.

Exclusion criteria (Figure 1) included the following: respondents who were diagnosed with chronic diseases or took medications that affect HbA1c levels and blood lipids, women who were pregnant and/or breastfeeding or menopause. The dropout criteria were less than 80% compliance with CHAGURO products, experiencing dangerous conditions such as diarrhea or allergies, and the respondents died.

Sample collection
In the two public health centers (puskesmas) that we chose, 111 patients with DM2 were matched with the criteria and participated in 60 days of intervention at Sleman Regency, Yogyakarta. At the end of the recruitment, out of a total of 111 individuals who were included and randomized, 84 respondents were selected for this subgroup analysis. A total of 23 respondents experienced dropout during follow-up, including loss of follow-up for personal reasons (n = 16), dislike of fish smell (n = 6), and hospitalization (n = 1).

Blood samples were taken from veins and stored in a sample tube that already contained ethylene diamine tetra-acetic acid (EDTA) fluid so that blood does not freeze. Blood sampling was carried out by a registered analyst and samples were analyzed at the Prima Diagnostika Clinical Laboratory, KH. Wakhid Hashim, No. 27 Yogyakarta.

Biomedical analysis of blood samples
HbA1c was analysed using the immunoassay nephelometry method; triglycerides were analysed using Trinder, and HDL and LDL using the Direk (precipitation) method that compresses HDL and LDL using polyvinyl sulfate or heparin at low pH, HDL and LDL levels. These were calculated as a difference from the total cholesterol value and levels contained in the supernatants. Cholesterol examination used the CHOD-PAP method (Cholesterol Oxidase–Peroxidase Aminoan-typirin) method with blanks and standards, the sample was then mixed and incubated at a temperature of 37 °C for 10 minutes, the sample absorbance reading and standard against blank was recorded in 60 minutes with a wavelength of 500 nm.

Data management and analysis
Statistical analysis includes independent and paired T-tests to analyze the effects of CHAGURO products on HbA1c, HDL-C, low-density lipoprotein cholesterol (LDL-C), triglycerides, and total cholesterol before and after the intervention. Qualitative data were analyzed using chi-squares and Mann-Whitney tests. Data were analyzed using Stata version 12.1 for Windows 8. All statistical tests were two-sided, with the significance level at 0.05.

Results and discussions
This experimental study was conducted to determine the clinical effects of CHAGURO products as functional foods for individuals with prediabetes with dyslipidemia. This study is also follow-up from a previous study in experimental mice. In particular, the 60-day intervention of functional food CHAGURO could lower the chol/HDL ratio in our subjects. However, an in-depth exploration of the variables related to obesity is required, in order to understand the complex schemes or mechanisms of siamese pumpkin and tuna-based powder (CHAGURO) as a functional food which is both antiobesity and antidiabetic.

Dietary compliance was monitored through the number of CHAGURO packs consumed by respondents per week (Figure 2). The result showed that there were no significant differences in self-reported dietary compliance per week between both groups (p > 0.05).

Follow-up was conducted once every two weeks in the first and second months of the intervention. The duration of each follow-up session was about 5 minutes. Patients who did not comply with CHAGURO consumption, with a rate of less than 80% compliance, were excluded from the study.

The characteristics of the respondents in this study can be seen in Table 1 below.
Figure 2. The trends of alteration of dietary compliance in CHAGURO.

| Education level             |                        |                       |       |       |
| College or more             | 7(24.14)               | 4(12.50)              | 2.677 | 0.262 |
| Middle, high school         | 16(55.17)              | 24(75.00)             |       |       |
| Less than primary school    | 6(20.69)               | 4(12.50)              |       |       |
| Physical activity level     |                        |                       |       |       |
| Low                         | 11(37.93)              | 11(34.38)             | 0.854 | 0.652 |
| Moderate                    | 15(51.72)              | 15(46.68)             |       |       |
| High                        | 3(10.34)               | 6(14.75)              |       |       |
The general characteristics of the participants enrolled in each group is shown in Table 1. The two study groups were matched in terms of mean age, marital status, job employment, education level, and physical activity level. However, gender differ significantly between the two groups. Among the two groups, there were no significant differences in the baseline characteristic of anthropometric variables, blood pressure, hereditary diabetes mellitus, and the accompanying disease.

The changes in macronutrient and micronutrient intake are presented in Table 2. There was a significant difference in carbohydrate intake in the LD group before and after 60 days of intervention. This may result in bias because carbohydrate intake is not controlled. There was an insignificant decrease in fat intake in the HD group, and fiber intake in both groups. Other nutrients such as energy, carbohydrate, protein, cholesterol, sugar, and sodium intake increased at the end of the intervention.

Changes in variables and mean differences in changes between the two groups after 60 days of intervention are presented in Table 3. Compared to baseline, there were no significant changes in the level of HbA1c, total cholesterol, LDL-C, and triglycerides after the intervention; although there was an insignificant decrease in total cholesterol and LDL-C. A significant improvement in the chol/HDL ratio was observed in the LD group (p < 0.05). However, HDL-C has decreased significantly in the HD group.

Functional food has been widely studied and, most commonly, chayote (Sechium edule) and tuna have shown beneficial effects in improving glycemic status and inflammation.\textsuperscript{11,14,15} Tuna fish contain docosahexaenoic acid (DHA), polyunsaturated fatty acids (PUFA) and eicosapentaenoic acid (EPA), which are known to have benefits in dyslipidemia and insulin resistance, and also physiological effects.\textsuperscript{16} This study showed that 7.5 g and 15 g CHAGURO did not result in a reduction in HbA1c, which is less consistent with previous research results.\textsuperscript{14,17} Comparison of the HbA1C level before and after the 60-day intervention did not differ significantly between groups (Figure 3). This means that CHAGURO consumption cannot lower the HbA1C level. This may be caused by a failure to control the level of carbohydrate intake during the intervention, which can be seen from the increase in carbohydrate intake before and after the intervention in both groups (Table 2). This study has not produced comprehensive results on the effect of CHAGURO on HbA1C levels. The HbA1C level can be used to evaluate long-term glycemic control of patients and can reflect mean blood glucose over the

BMI - body mass index; SBP - systolic blood pressure; DBP - diastolic blood pressure; SD - standard deviation.
last 8 to 12 weeks. One of the reasons for this study result is the short-term duration of the intervention. Sakung et al. also reported no differences in blood glucose with chayote consumption in subjects with prediabetes.

Total cholesterol, LDL-C, HDL-C, and triglyceride levels were not significantly altered with 7.5 g and 15 g of CHAGURO in this study, except HDL-C levels, which decreased significantly in the 15 g group of CHAGURO. However, the cholesterol-lowering effects of CHAGURO are shown to be greatest in the group with lower baseline lipids.

### Table 2. Changes in nutrition and glucose intake during research.

| Variables       | Pre-test Mean ± SD | Post-test Mean ± SD | p^a  |
|-----------------|--------------------|---------------------|------|
| Nutrition intake|                    |                     |      |
| Energy (kcal/day)|                   |                     |      |
| CHAGURO 7.5 g   | 1059.15 ± 360.20   | 1263.46 ± 521.52    | 0.098b |

CI - confidence interval at 95%; LDL-C - low-density lipoprotein cholesterol; HDL - high-density lipoprotein; SD - standard deviation.
The chol/HDL-C ratio has a high correlation with the levels of LDL particles. Previous studies have shown that it is a strong cardiovascular risk marker.\textsuperscript{20–22} Omega-3 fatty acids in tuna can be responsible for lowering the lipid profile as a cardiovascular protective nutrient. Through activation of peroxisome proliferator-activated receptor (PPAR), omega-3 fatty acids have the ability to lower the fasting concentration of plasma trygliserides, reduce inflammation, and increase insulin sensitivity.\textsuperscript{23}

Limitations of the study design should be noted. Potential dietary confounders to evaluate the effects of CHAGURO were homogenized between groups by providing a general diet. The limitation of this study lies in the short-term intervention. Considering that the duration of a 60-day intervention is too short for some variables such as HbA1C to show significant changes. Another limitation was that the subjects were not fully blinded. However, this study shows that CHAGURO has an effect in lowering the chol/HDL ratio.

Conclusions

In prediabetes individuals with dyslipidemia, experimental research intervention or administration of 7.5 g of siamese pumpkin and tuna seed (CHAGURO) can significantly improve the chol/HDL ratio. Thus, CHAGURO can be a functional food alternative for individuals with prediabetes and dyslipidemia in improving chol/HDL ratio, but further studies are needed to support this data.

Dear Sudargo et al, Good job in improving the readability of your paper and friends. However, there is something important that you are missing. Your research "The effect of a siamese pumpkin and tuna-based powder (CHAGURO) diet in improving chol/HDL ratios in prediabetes individuals with dyslipidemia: a randomised trial". In the abstract section (precisely the method section), it lacks detail and specifically mentions the participant criteria for participants (your research on prediabetes individuals with dyslipidemia), what is the value of glucose or HbA1c levels? so that the subject is said to be "prediabetes individuals with dyslipidemia".

However, you can simply re-mention the good and correct abstract according to my suggestions and comments in this comment section (by replying to the comment column) *The latest full abstract according to my comments is written in the comments column by answering my review! I wait!

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Clinical Nutrition, Food Sciences, Obesity and Non-communicable diseases.

We confirm that we have read this submission and believe that we have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
This manuscript by Sudargo et al., presents the results of the effect of administering CHAGURO (a product of the combination of siamese pumpkin and tuna-based powder) on the lipid profile in prediabetes individuals with dyslipidemia. Several things need and must be considered by the researcher or the author of this manuscript for future improvement! Some issues are listed below:

1. **Title:** The title needs to be rewritten, as HbA1c shows no improvement.

2. **Abstract:** The abstract needs to be restructured: this research is a quasi-experimental research, please include it in the abstract! Mention the survey method used in this research (do you use google form or what?). Please use "Food Intake" instead of "Food Eating". Mention the results of initial data collection that mention or describe that the sample has prediabetes with dyslipidemia.

3. **Introduction:** The sentence "It can be concluded that the combination of siamese pumpkin and tuna has nutritional content that has the potential to improve the lipid profile and blood glucose so that it is protective against cardiovascular disease and type 2 DM" please rewrite, the sentence is not correct.

4. **Methods:**
   - In the sentence "The study showed that a 3:1 ratio of tuna and pumpkin could have the best effect on HbA1c, triglycerides, HDL, low-density lipoprotein (LDL), and cholesterol levels in diabetic and dyslipidemia mice compared to other formulas." Please add citations that refer to the research!
   - Why didn't the author test bioactive compounds? such as antioxidant activity? This is to support the research you are doing. Estimation of improving HDL-C, and chol/HDL of what substance or compound? it is still unclear and has not been found in the paper!
In the sub method 2: Results of mRNA, micronutrient, and organoleptic siamese pumpkin and tuna-based powder products (CHAGURO)" what do you mean by mRNA? please clarify!

This research is a quasi-experimental research, please improve it!

The design study needs to be clarified and detailed, described from "Figure 1", such as inclusions, exclusions etc.

5. Results and Discussion:
   - In the section "Table 1. Distribution of the characteristics of the research respondents (n = 61)." Why did the authors not list the characteristics of the lipid profile and HbA1c?
   - In table 2, please use the term "Pre and Post test", not Research beginning and End of research (this is not appropriate).
   - In table 3, it needs to be rewritten. Why did the author not display the result data categorized according to gender. Because there are differences in lipid profile levels in women and men.

6. Conclusion: The conclusion must be in accordance with the research results presented in the abstract and give power to the title! Please rewrite the conclusion section.

By seeing and considering the limitations of this research, I and the reviewer team give Sudargo et al. the opportunity to improve this paper!

Is the work clearly and accurately presented and does it cite the current literature?
Partly

Is the study design appropriate and is the work technically sound?
Partly

Are sufficient details of methods and analysis provided to allow replication by others?
Partly

If applicable, is the statistical analysis and its interpretation appropriate?
Yes

Are all the source data underlying the results available to ensure full reproducibility?
Yes

Are the conclusions drawn adequately supported by the results?
Partly

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Clinical Nutrition, Food Sciences, Obesity and Non-communicable diseases.
We confirm that we have read this submission and believe that we have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however we have significant reservations, as outlined above.

Toto Sudargo, Department of Nutrition and Health, Universitas Gadjah Mada, Yogyakarta, Indonesia

Dear reviewer, thank you so much for the constructive suggestion in our articles. Hereby we revised the article accordingly. The suggested changes and extensions have been implemented in the revised paper.

Competing Interests: None.

Author Response 26 Feb 2022

Atika Anif Prameswari, Universitas Gadjah Mada, Yogyakarta, Indonesia

1. Abstract: We have inserted the sentence “Respondents in each group ranged in age from 30 to 60 years old, with fasting blood sugar levels of 100 to 125 mg/dL and cholesterol levels of 200 mg/dL.”

2. Abstract: We have replaced “SQ-FFQ (Semi Quantitative-Food Frequency Questionnaire) interview, body mass index (BMI), and physical activity using International Physical Activity Questionnaires-Short Form (IPAQ-SF).” with “SQ-FFQ interview, BMI, and physical activity using IPAQ-SF.”

Competing Interests: none
The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage
