Abstract
In this paper we introduce new categorical notions and give many examples. In an earlier paper we proved that the Bridgeland stability space on the derived category of representations of $K(l)$, the $l$-Kronecker quiver, is biholomorphic to $\mathbb{C} \times H$ for $l \geq 3$. In the present paper we define a new notion of norm, which distinguishes $\{D^b(K(l))\}_{l \geq 2}$. More precisely, to a triangulated category $T$ which has property of a phase gap we attach a non-negative real number $\|T\|^\varepsilon$. Natural assumptions on a SOD $T = \langle T_1, T_2 \rangle$ imply $\|\langle T_1, T_2 \rangle\|^\varepsilon \leq \min\{\|T_1\|^\varepsilon, \|T_2\|^\varepsilon\}$. Using the norm we define a topology on the set of equivalence classes of proper triangulated categories with a phase gap, such that the set of discrete derived categories is a discrete subset, whereas the rationality of a smooth surface $S$ ensures that $[D^b(point)] \in Cl([D^b(S)])$. Categories in a neighborhood of $D^b(K(l))$ have the property that $D^b(K(l))$ is embedded in each of them. We view such embeddings as non-commutative curves in the ambient category and introduce categorical invariants based on counting them. Examples show that the idea of non-commutative curve-counting opens directions to new categorical structures and connections to number theory and classical geometry. We give a definition, which specializes to the non-commutative curve-counting invariants. In an example arising on the A side we specialize our definition to non-commutative Calabi–Yau curve-counting, where the entities we count are a Calabi–Yau modification of $D^b(K(l))$. In the end we speculate that one might consider a holomorphic family of categories, introduced by Kontsevich, as a non-commutative extension with the norm, introduced here, playing a role similar to the classical notion of degree of an extension in Galois theory.

1 Introduction

Motivated by M. Douglas’s work in string theory T. Bridgeland defined in [10] a map:

\[
\text{\{triangulated categories\}} \xrightarrow{\text{Stab}} \text{\{complex manifolds\}}.
\] (1)

For a triangulated category \( \mathcal{T} \) the associated complex manifold \( \text{Stab}(\mathcal{T}) \) is referred to as the space of stability conditions (or the stability space or the moduli space of stability conditions) on \( \mathcal{T} \).

The map (1) behaves well with respect to orthogonal decompositions (Definition 5.1). Due to lack of a reference in the literature we show this in Sect. 5. In particular, there is a bijection

\[
\text{Stab}(\mathcal{T}_1 \oplus \mathcal{T}_2 \oplus \cdots \oplus \mathcal{T}_n) \cong \text{Stab}(\mathcal{T}_1) \times \text{Stab}(\mathcal{T}_2) \times \cdots \times \text{Stab}(\mathcal{T}_n),
\] (2)

which is biholomorphism, when the categories are with finite rank Grothendieck groups (Proposition 5.2). Our previous paper [19, Theorem 1.1] contains examples of semi-orthogonal decomposition, SOD, \( \mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2 \rangle \) where \( \text{rank}(K_0(\mathcal{T})) = 2 \) and \( \text{Stab}(\mathcal{T}) \) is not biholomorphic to \( \text{Stab}(\mathcal{T}_1) \times \text{Stab}(\mathcal{T}_2) \).

The behavior of the map (1) with respect to general SOD has been studied in [16]. This is a difficult problem and no formula relating \( \text{Stab}(\langle \mathcal{T}_1, \mathcal{T}_2 \rangle) \) and \( \text{Stab}(\mathcal{T}_1), \text{Stab}(\mathcal{T}_2) \) is obtained.

In this paper using Bridgeland stability conditions we define (Definition 4.11) for any \( 0 < \varepsilon < 1 \) a function (the domain is explained below and it does not depend on \( \varepsilon \)):

\[
\text{\{triangulated categories with a phase gap\}} \xrightarrow{\|\cdot\|_\varepsilon} [0, \pi(1 - \varepsilon)] \text{ and we denote } \|\mathcal{T}\|_\varepsilon = \pi(1 - \varepsilon) - \|\mathcal{T}\|_\varepsilon.
\] (3)
and prove (Theorem 6.1) that if $\mathcal{T} = \langle T_1, T_2 \rangle$ is a semi-orthogonal decomposition in which $\mathcal{T}$ is proper,\(^1\) $\operatorname{rank}(K_0(\mathcal{T})) < \infty$, $T_1$ and $T_2$ have phase gaps, then $\mathcal{T}$ has phase gap as well and

$$\|\langle T_1, T_2 \rangle\|_\varepsilon \geq \max\{\|T_1\|_\varepsilon, \|T_2\|_\varepsilon\} \Rightarrow \|\langle T_1, T_2 \rangle\|_\varepsilon \leq \min\{\|T_1\|_\varepsilon, \|T_2\|_\varepsilon\}. \quad (4)$$

For the proof of this inequality we employ the method for gluing of stability conditions in [16], crucial role has also [11, Lemma 4.5] which ensures certain finiteness property of a stability condition with a phase gap.

The function (3) depends on $\varepsilon \in (0, 1)$, however the three subsets of its domain determined by the three conditions on the first row in the following table do not depend on $\varepsilon$ (Lemma 4.16):

| Categories with:            | $\|\cdot\|_\varepsilon = 0$ | $0 < \|\cdot\|_\varepsilon < \pi(1-\varepsilon)$ | $\|\cdot\|_\varepsilon = \pi(1-\varepsilon)$ |
|-----------------------------|-------------------------------|-----------------------------------------------|-----------------------------------------------|
| examples:                   |                                |                                               |                                               |
| for any acyclic quiver      |                                |                                               |                                               |
| $Q \overset{D^b(Q)}{\longrightarrow}$ is here if $Q$ is Dynkin or affine, any discrete derived category is here | $D^b(K(l_1)) \oplus \cdots \oplus D^b(K(l_N))$ where $N \in \mathbb{Z}_{\geq 1}, l_i \geq 3$ for some $i$ | $D^b(\mathbb{P}^1 \times \mathbb{P}^1)$, $D^b(\mathbb{P}^m) \geq 2$, $D^b(\mathbb{F}_m) m \geq 0$, many wild quivers as in Prop. 8.5 (a) |

Further examples can be obtained by using (4) and the property that for a proper $\mathcal{T}$ with $\operatorname{rank}(K_0(\mathcal{T})) \geq 3$ we show in Proposition 11.9 that the following condition: 2

for each $l \in \mathbb{N}$ there exists a full exceptional collection $(E_0, E_1, \ldots, E_n)$ and integers $0 \leq i < j \leq n$ for which $\operatorname{hom}^{\min}(E_i, E_j) \geq l \quad (5)$

implies $[D^b(\text{point})] \in \operatorname{Cl}(\{\mathcal{T}\})$. In Proposition 8.5 we verify (5) in $D^b(X)$ for any smooth complete rational surface $X$ and for some higher dimensional smooth varieties. A conjecture stated by Orlov says that a surface over an algebraically closed field admits a full exceptional collection only if it is rational (see e.g. [41, p. 5]). If this conjecture holds, then the presented results would imply that for any smooth projective surface $S$ with a full exceptional collection holds (5) and hence

\(^1\) By proper we mean that $\sum_{i \in \mathbb{Z}} \operatorname{hom}^i(X, Y) < +\infty$ for any two objects $X, Y$ in $\mathcal{T}$ (see also Sect. 2 dedicated to Notations).

\(^2\) The meaning of $\operatorname{hom}^{\min}(A, B)$ can be seen in formula (14).
Let $X$ denote a smooth projective variety $X$, different from $\mathbb{P}^1$, with a full exceptional collection. Is there $X$, s.t. $[D^b(\text{point})] \notin \text{Cl}([D^b(X)])$? Is there $X$ and a natural number $N \in \mathbb{N}$ s.t. for any full exceptional collection $(E_0, \ldots, E_n)$ in $D^b(X)$ and any $0 \leq i < j \leq n$ we have $\text{hom}_{\text{min}}(E_i, E_j) \leq N$?

A positive answer of some of the questions in 1.1 with $\dim(X) = 2$ would be a counterexample of Orlov conjecture.

Another class of categorical invariants introduced in this paper is motivated by the following question (many of these invariants behave in a certain sense monotone with respect to SOD):

For the topology from Sect. 11 any category (except $D^b(A_1)$) in Table 1 is in a neighborhood of $N\mathbb{P}^l$ for some $l$ (following Kontsevich–Rosenberg [32] we denote sometimes $D^b(K(l + 1))$ by $N\mathbb{P}^l$). More precisely, there is a SOD $(N\mathbb{P}^l, A)$ for some $l$ and some $A$. Recalling that Gromov-Witten invariants count pseudo-holomorphic curves, we view such embeddings of $N\mathbb{P}^l$ into $T$ as analogous to a “pseudo-holomorphic curve” in the category $T$ and ask a question: can we count such entities in a given $T$, how many are they?

In Sect. 12 and in [20] we show that the answer is positive. The idea is: for two triangulated categories $A, T$, a subgroup $\Gamma \subseteq \text{Aut}(T)$, and a choice of some additional restrictions $P$ of fully faithful functors we define the set of equivalence classes of fully faithful functors from $A$ to $T$ satisfying $P$ with two functors $F, F'$ being equivalent iff $F \circ \alpha \cong \beta \circ F'$ for some $\alpha \in \text{Aut}(N\mathbb{P}^l), \beta \in \Gamma$. This set is denoted by $C_{A,P}^{\Gamma}(T)$ (see Definition 12.5). We prefer to choose some $A$, which is non-trivial but well studied.

The studies in this paper naturally impose $N\mathbb{P}^l$ as our first choice - we consider also $N\mathbb{P}^{l-1}$, which is a category generated by an orthogonal exceptional pair. We refer to $N\mathbb{P}^l$ as a non-commutative curve and by rescaling $\|\cdot\|_{\frac{1}{2}}$ (see Sect. 12.1) we define an invariant:

\[
\begin{align*}
\{ \text{triangulated categories with a phase gap} \} & \to [0, +\infty], \quad \text{s.t.} \\
\dim_{nc}(\langle A, B \rangle) & \geq \max\{\dim_{nc}(A), \dim_{nc}(B)\} \\
\dim_{nc}(N\mathbb{P}^l) & = l \quad l \geq 0, \\
\dim_{nc}(N\mathbb{P}^{l-1}) & = 0
\end{align*}
\]

(6)

to which we refer to as “non-commutative genus”. In particular, $N\mathbb{P}^l$ is a non-commutative curve of genus $l$ for $l \geq 0$. Although $N\mathbb{P}^{l-1}$ has homological dimension 0 we refer to it as a non-commutative curve of genus $−1$ (see Remark 12.2 for further motivation).

Using the inequality in (6) we have derived vanishing theorem for $C_{N\mathbb{P}^l,P}^{\Gamma}(T)$ for certain choice of $P$ (see Remark 12.6). Choosing $A = N\mathbb{P}^l$, assuming that $T$ is $\mathbb{K}$-linear and choosing the additional restriction $P$ of the functors to be $\mathbb{K}$-linear, we write just $C_{P}^{\Gamma}(T)$ instead of $C_{N\mathbb{P}^l,P}^{\Gamma}(T)$ and refer to this set as the set of non-commutative curves of genus $l$ in $T$ modulo the subgroup $\Gamma$. Furthermore, by fixing a stability condition $\sigma \in \text{Stab}(T)$ we strengthen the restriction $P$ depending on $\sigma$ to define the set of $\sigma$-semistable, resp. $\sigma$-stable non-commutative curves in $T$ and denote it by
Some new categorical invariants

\( C_{l,\sigma}^\Gamma(T) \), resp. \( C_{l,\sigma}^\Gamma_{\Lambda,B}(T) \) (Definition 12.12). The definitions of the counting invariants introduced here are carefully explained in a subsequent work [20].

From this vanishing criterion (174), Remark 12.7 and after determining \( \dim_{nc}(D^b(Q)) \) for affine and Dynkin \( Q \) (see Remark 12.1) follow these vanishings:

If \( l \geq 2 \) and \( Q \) is affine acyclic quiver \( \Rightarrow C_{l,\sigma}^\Gamma(T) = 0 \), (7)

If \( l \geq 1 \) and \( Q \) is Dynkin quiver \( \Rightarrow C_{l,\sigma}^\Gamma(T) = 0 \). (8)

It is interesting to find further examples of wild quivers \( Q \) with \( \dim_{nc}(D^b(Q)) < \infty \), we propose potential examples, see Conjecture 1.3, analogous vanishings for \( C_{l,\sigma}^\Gamma(T) \) for big enough \( l \) would follow by the vanishing criterion (174).

It is easy to prove that \( C_{l,\sigma}^\Gamma(T) \) are computed for two affine quivers in [20, Section 6], and estimated for \( D^b(P^2) \) in [20, Section 8]. In Sect. 12.3 here we present the results of these computations. In particular, part of Proposition 12.10 is that \( C_{l,\sigma}^\Gamma(T) \) is finite for all \( l \) and non-empty if \( l = 3m - 1 \) for some Markov number \( m \), where \( P^2 \) is the complex projective plane and \( Aut_{C}(D^b(P^2)) \) is the group of \( C \)-linear auto-equivalences of \( P^2 \). Furthermore, Corollary 12.11 is that the Markov’s conjecture in number theory and a conjecture by Tyurin ([36, p. 100] or [25, Section 7.2.3]) are true iff for each Markov number \( m \neq 1, m \neq 2 \) we have \( C_{3m-1}^\Gamma(T) = 2 \). Via the latter Corollary in future works we plan to approach Markov’s conjecture using homological mirror symmetry and applying A side techniques for computing the non-commutative curve-counting invariants.

In Sect. 12.4 we explain an example, where \( C_{l,\sigma}^\Gamma(T) \) takes all possible values in \( \{0, 1, 2 = C_{l,\sigma}^\Gamma(T)\} \) as \( \sigma \) varies in \( Stab(T) \) (the proof is in the master thesis [6]).

Section 12.5 contains a conjectural example of finite sets \( C_{A,B}^\Gamma(T) \) of different origin (the proof is postponed for future work as well). Here \( T \) is the so called Fukaya category of an elliptic curve, \( Fuk(E) \). In this case we set \( A \) to be a a Calabi-Yau modification of \( D^b(K(l)) \), denoted by \( CY(l) \). The question about the cardinalities of \( C_{CY(l),\mathcal{C}}^\Gamma(T) \) for higher genus curves should be related to counting geodesics on \( S \).

Finally (Sect. 13), relating our norm to the notion of holomorphic family of categories introduced by Kontsevich we suggest a framework in which sequences of holomorphic families of categories are viewed as sequences of extensions of non-commutative manifolds.
This paper is the beginning of a longer pursuit motivated by the invariants introduced here. In [20] we extend our studies of $C_{A,P}(T)$ beyond counting: besides numbers we extract from $C_{A,P}(T)$ categorical versions of classical geometric structures which open new perspectives in non-commutative geometry.

1.1. We give here more details on the definition of $\|T\|_\epsilon$ and on the examples.

By definition each stability condition $\sigma \in \text{Stab}(T)$ determines a set of non-zero objects in $T$ (called semi-stable objects) labeled by real numbers (called phases of the semistable objects). The semi-stable objects correspond to the so called “BPS” branes in string theory. The set of semi-stable objects will be denoted by $\sigma^{ss}$, and $\phi_\sigma(X) \in \mathbb{R}$ denotes the phase of a semi-stable $X$. For any $\sigma \in \text{Stab}(T)$ we denote by $P_\sigma$ the subset of the unit circle $\{\exp(i\pi \phi_\sigma(X)) : X \in \sigma^{ss}\} \subset S^1$. A categorical analogue of the density of the set of slopes of closed geodesics on a Riemann surface was proposed in [18]. In [18, section 3] the focus falls on constructing stability conditions for which the set $P_\sigma$ is dense in a non-trivial arc of the circle. The result is the following characterization of the map (1), when restricted to categories of the form $D^b(\text{Rep}_K(Q))$ ($Q$ denotes an acyclic quiver):

| Dynkin quivers (e.g. $\circ \rightarrow \circ$) | $P_\sigma$ is always finite |
|-----------------------------------------------|---------------------------|
| Affine quivers (e.g. $\circ \rightarrow \circ \rightarrow \circ$) | $P_\sigma$ is either finite or has exactly two limit points |
| Wild quivers (e.g. $\circ \rightarrow \circ \rightarrow \circ$) | $P_\sigma$ is dense in an arc for a family of stability conditions |

In [21, Proposition 3.29] are constructed stability conditions $\sigma \in \text{Stab}(D^b(Q))$ with two limit points of $P_\sigma$ for any affine quiver $Q$ (by $D^b(Q)$ we mean $D^b(\text{Rep}_k(Q))$).

Stability conditions on wild quivers whose set of phases are dense in an arc were constructed in [18], however for them the set of phases is still not dense in the entire $S^1$, i.e. $P_\sigma$ does misses a non-trivial arc, in which case we say for short that $P_\sigma$ has a gap. In particular all the categories in table (9) are examples of what we call in this paper a triangulated category with phase gap, this is a triangulated category $T$ for which there exists a full $^3$ $\sigma \in \text{Stab}(T)$ whose set of phases $P_\sigma^T$ has a gap. Stability conditions whose set of phases is not dense in $S^1$ and their relation to so called algebraic stability conditions have been studied in [37]. In particular the results in [37] imply that when $\text{rank} K_0(T) < \infty$, then $T$ has a phase gap iff there exists a bounded t-structure in $T$ whose heart is of finite length and has finitely many simple objects (Lemma 4.7). Whence the domain of the invariant (3) contains also the CY3 categories discussed in [12].

By definition $\|T\|_\epsilon$ is the supremum of $^4$ $\text{vol}(P_\sigma)/2$ as $\sigma$ varies in the subset $\text{Stab}_b(T) \subset \text{Stab}(T)$ of those stability conditions $\sigma$ for which $P_\sigma$ misses at least one closed $\epsilon$-arc (see Definitions 38, 4.3).

---

$^3$ We recall what is a full stability condition in Sect. 4.1. The stability conditions on the third raw of (9) are full.

$^4$ For a Lebesgue measurable subset $X \subset S^1$ we denote by $\text{vol}(X)$ its Lebesgue measure with $\text{vol}(S^1) = 2\pi$. 
From the definition and table (9) it follows that for any acyclic quiver $Q$ the norm $\| D^b(Q)\|_\varepsilon$ vanishes iff $Q$ is Dynkin or affine. Thus, using [19, table (4)] we obtain the table

| $Q$          | $\| D^b(Q)\|_\varepsilon$ | Stab($D^b(Q)$) |
|--------------|----------------------------|-----------------|
| $\circ \rightarrow \circ$ or $\circ \rightarrow \circ$ | $D^b(Q)\|_\varepsilon = 0$ | $\mathbb{C} \times \mathbb{C}$ |
| $K(l), l \geq 3$ | $D^b(Q)\|_\varepsilon > 0$ | $\mathbb{C} \times \mathcal{H}$ |

(10)

and [19, Conjecture 1.2] can be reformulated as follows:

**Conjecture 1.2** Let $0 < \varepsilon < 1$ and let $Q$ be any acyclic quiver. The stability space Stab($D^b(Q)$) is affine (of the form $\mathbb{C}^n$) iff $\| D^b(Q)\|_\varepsilon = 0$.

In table (9) we see that the map (1) has the same value (up to biholomorphism) on all the categories $\{D^b(K(l))\}_{l \geq 3}$. In this paper we compute $\| D^b(K(l))\|_\varepsilon$ for any $l$ and $0 < \varepsilon < 1$ and show:

$$\| D^b(K(l_1))\|_\varepsilon < \| D^b(K(l_2))\|_\varepsilon \iff l_1 < l_2 \text{ and } 3 \leq l_2$$

(11)

$$l \geq 2 \Rightarrow \| D^b(K(l))\|_\varepsilon = \arccos \left( \frac{2}{7} \right).$$

(12)

Some criteria ensuring that $\| T\|_\varepsilon = \pi(1-\varepsilon)$ explained below imply that for many of the wild quivers $Q$ we have $\| D^b(Q)\|_\varepsilon = \pi(1-\varepsilon)$ (see Proposition 8.5 (a)) and also $\| D^b(X)\|_\varepsilon = \pi(1-\varepsilon)$ where $X$ is $\mathbb{P}^n$, $n \geq 2$, $\mathbb{P}^1 \times \mathbb{P}^1$, $\mathbb{F}_a$, $a \geq 0$ or a smooth algebraic variety obtained from these by a sequence of blow ups in finitely many points (see Proposition 8.5e, f), for $n = 1$ we have $\| D^b(\mathbb{P}^1)\|_\varepsilon = 0$. Actually, the condition $\| T\|_\varepsilon < \pi(1-\varepsilon)$ imposes restrictions on the full exceptional collections in $T$ (see Corollary 8.4).

The criteria for $\| T\|_\varepsilon = \pi(1-\varepsilon)$ obtained here do not apply to category of the form $T \cong D^b(K(l_1)) \oplus D^b(K(l_2)) \oplus \cdots \oplus D^b(K(l_N))$ and we do prove that $\| T\|_\varepsilon < \pi(1-\varepsilon)$ in this case.

We expect that the criterion in Corollary 8.3 does not apply to all wild quivers, and we do know that its corollary, Corollary 8.5 (a), cannot be applied to all of them, for example, to the following:

$$S_1 = \begin{array}{c} \circ \rightarrow \circ \\ a_2 \end{array}, \quad S_2 = \begin{array}{c} a_1 \rightarrow a_2 \\ a_3 \end{array}, \quad S_3 = \begin{array}{c} a_1 \rightarrow a_2 \rightarrow a_3 \\ a_4 \end{array}$$

We conjecture, that:

**Conjecture 1.3** For $i = 1, 2, 3$ we have $0 < \| D^b(S_i)\|_\varepsilon < \pi(1-\varepsilon)$, which is equivalent to $\dim_{nc}(D^b(S_i)) < \infty$ (see (6)). Furthermore we conjecture that $C_i^{[\text{Id}]}(T)$ is finite for all $l \geq 1$. 

1.2. It follows a brief discussion on the computations of $\|T\|_\varepsilon$. In Sect. 7 we denote $\mathcal{T}_l = D^b(K(l))$ and compute $\|\mathcal{T}_l\|_\varepsilon$. To that end we start in Sect. 7.1 by recalling the construction and some properties of the helix of exceptional objects $\{\sigma_j\}_{j \in \mathbb{Z}}$ in $\mathcal{T}_l$ (infinite in both directions sequence of exceptional objects and any two consecutive form a full exceptional pair). In Sect. 7.2 we determine explicitly the set of phases $P^l_\sigma$ for each $\sigma \in \text{Stab}(\mathcal{T}_l)$ and each $l \geq 2$ (Proposition 7.4). It turns out that for $l \geq 3$ a stability condition has $\text{vol} \left( P^l_\sigma \right) \neq 0$ and satisfies $\sigma \in \text{Stab}_\varepsilon(\mathcal{T}_l)$ iff there exists $j \in \mathbb{Z}$ such that $s_j, s_{j+1} \in \sigma^{ss}$ and $\varepsilon < \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) < 1$, the set $P^l_\sigma$ for such a $\sigma$ is the set of fractions $\{n/m : (n, m) \in \Delta_+(K(l))\}$ appropriately embedded in the circle via a function depending on the stability condition. In Lemma 7.3 we shed light on the structure of the set $\{n/m : (n, m) \in \Delta_+(K(l))\}$ (see formulas 80, 81) and use it in the proof of Proposition 7.4.

We start Sect. 7.3 by deriving a formula expressing the non-vanishing numbers $\text{vol} \left( P^l_\sigma \right) / 2$ as a smooth function depending on $\frac{\|Z(s_{j+1})\|}{\|Z(s_j)\|}$ and $\phi_\sigma(s_{j+1}) - \phi_\sigma(s_j)$ for any $j \in \mathbb{Z}$ (see Proposition 7.6). After computing partial derivatives of this function we find that the supremum of $\text{vol} \left( P^l_\sigma \right) / 2$ as $\sigma$ varies in $\text{Stab}_\varepsilon(\mathcal{T}_l)$ is equal to $\text{vol} \left( P^l_\sigma \right) / 2$ where $\sigma$ has $s_j, s_{j+1} \in \sigma^{ss}$, $\frac{\|Z(s_{j+1})\|}{\|Z(s_j)\|} = 1$ and $\phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) = \varepsilon$. The precise formula for $\|\mathcal{T}_l\|_\varepsilon$ is in Proposition 7.7 and it produces (11), (12). In particular it follows that

$$\lim_{l \to +\infty} \|\mathcal{T}_l\|_\varepsilon = \pi(1 - \varepsilon).$$

Section 8 contains examples of $T$ with $\|T\|_\varepsilon = \pi(1 - \varepsilon)$ (Proposition 8.5). This section is based on (13) and the observation (Proposition 8.1) that for any exceptional pair $(E_1, E_2)$ in a proper $T$ holds $\|\langle E_1, E_2 \rangle\|_\varepsilon \geq \|\mathcal{T}_l\|_\varepsilon$ where $l = \text{hom}^{\text{fin}}(E_1, E_2)$. It follows that the condition $\|T\|_\varepsilon < \pi(1 - \varepsilon)$ imposes restrictions on $\text{hom}^{\text{fin}}(E_i, E_j)$ in a full exceptional collection $(E_0, \ldots, E_n)$ (see Corollary 8.4).

Section 9 is devoted to the proof that $\left\| D^b(K(l_1)) \oplus \cdots \oplus D^b(K(l_N)) \right\|_\varepsilon < \pi(1 - \varepsilon)$ for any $N \in \mathbb{Z}_{\geq 1}$ and any $0 < \varepsilon < 1$. Using the results for the sets $P^l_\sigma$ from Sects. 7.2, 7.3 we show here that, whenever $P^l_\sigma$ is contained in $C \cup -C$ for an open arc $C \subset \mathbb{S}^1$ with length less than $\pi$, then for some closed arc $p^l_\sigma \subset C \cap P^l_\sigma$ the set $P^l_\sigma \setminus (p^l_\sigma \cup -p^l_\sigma)$ is at most countable, and furthermore, provided that the length of $C$ is fixed, we show that when some of the end points of $p^l_\sigma$ is very close to some of the end points of $C$, then $p^l_\sigma$ itself has very small length (Corollary 9.3). Due to the fact, proven in Sect. 5, that for any orthogonal decomposition $T = \mathcal{T}_1 \oplus \cdots \oplus \mathcal{T}_n$ and any $\sigma \in \text{Stab}(T)$ holds $P^l_\sigma = \bigcup_{i=1}^n P^l_{\sigma_i}$, where $(\sigma_1, \ldots, \sigma_n)$ is the value of the map (2) at $\sigma$ (see Proposition 5.2 and Corollary 5.5), the proof of the desired inequality reduces to proving that the measure of union of arcs $\cup_{i=1}^n p^l_{\sigma_i} \subset C$ of the type explained above, cannot become arbitrary close to the length of $C$. Having proved this for one arc (in Sect. 7.3) we perform induction and the tool for the induction step is the already discussed Corollary 9.3.

In Sect. 10 we discuss the class of discrete derived categories and show that $\|T\|_\varepsilon = 0$ for any such category. These categories were introduced by Vossieck [42], they were
classified in [4] and thoroughly studied in [14], whereas the topology of the stability spaces on them were studied in [13, 37], in particular it was shown that these spaces are all contractible. This class contains the categories \( D^b(Q) : Q \) is Dynkin, and the discrete derived categories not contained in this list are of the form \( D^b(\Lambda(r, n, m)) \) for \( n \geq r \geq 1 \) and \( m \geq 0 \), where \( \Lambda(r, n, m) \) is the path algebra of the quiver with relations shown on [37, Section 4.3, Figure 1]. Actually, we show that if \( T \) is a category with phase gap, s.t. every heart of a bounded t-structure has finitely many indecomposable objects up to isomorphism, then \( \| T \|_\varepsilon = 0 \).

1.3. Using the helix \( \{s_j\}_{j \in \mathbb{Z}} \) in \( D^b(K(l + 1)) \cong N^\mathbb{P} \) we can explain what we mean by a \( \sigma \)-semistable non-commutative curve (see Definition 12.12 for precise statement). Let \( \text{Stab}(T) \neq \emptyset \) and \( \sigma \in \text{Stab}(T) \). Recall that a non-commutative curve of genus \( l \) in \( T \) is equivalence class of fully faithful exact \( \mathbb{K} \)-linear functors from \( N^\mathbb{P} \) to \( T \) (equivalence is re-parametrization in the domain), we will say that the curve is \( \sigma \)-semistable, resp. \( \sigma \)-stable, if for infinitely many, resp. for all, \( j \in \mathbb{Z} \) the object \( F(s_j) \in T \) is \( \sigma \)-semistable object (it does not matter which functor \( F \) we take as a representative). We denote the set of \( \sigma \)-semistable, resp. \( \sigma \)-stable, non-commutative curves of genus \( l \), and modulo subgroup \( \Gamma \subset \text{Aut}(N^\mathbb{P}) \), by \( C^\Gamma_{l, \sigma}(T) \), resp. \( C^\Gamma_{l, \sigma}(T) \).

Our basic example is \( C^\Gamma_{l, \sigma}(N^\mathbb{P}) \), \( l \geq 1 \). First note that from Remark 12.3 it follows that \( C^\Gamma_{l, \sigma}(N^\mathbb{P}) = \delta_{i, j} \) for \( i, j \geq 0 \). In Propositions 12.13, 7.2 is shown that for any \( l \geq 1 \) and any \( \sigma \in \text{Stab}(N^\mathbb{P}) \) we have one of the following possibilities

- only two consecutive elements in the helix, of the form \( s_j, s_{j+1} \), are semi-stable and \( \phi_\sigma(s_{j+1}) > \phi_\sigma(s_j) + 1 \), in particular \( C^\Gamma_{l, \sigma}(N^\mathbb{P}) = 0 \)
- all elements \( \{s_j\}_{j \in \mathbb{Z}} \) are semistable and \( \phi_\sigma(s_{j+1}) = \phi_\sigma(s_j) + 1 \) for some \( j \in \mathbb{Z} \), hence \( C^\Gamma_{l, \sigma}(N^\mathbb{P}) = 1 \)
- all elements \( \{s_j\}_{j \in \mathbb{Z}} \) are semistable and \( \phi_\sigma(s_j) < \phi_\sigma(s_{j+1}) < \phi_\sigma(s_j) + 1 \) for all \( j \in \mathbb{Z} \), hence \( C^\Gamma_{l, \sigma}(N^\mathbb{P}) = 1 \)

2 Notations

In this paper the letters \( T \) and \( A \) denote a triangulated category and an abelian category, respectively, and \( \mathbb{K} \) denotes an algebraically closed field. The shift functor in \( T \) is designated by \( [1] \). We write \( \text{Hom}^i(X, Y) \) for \( \text{Hom}(X, Y[i]) \) and, if \( T \) is \( \mathbb{K} \)-linear, we write \( \text{hom}^i(X, Y) \) for \( \text{dim}_\mathbb{K}(\text{Hom}(X, Y[i])) \), where \( X, Y \in T \). For \( X, Y \in A \), writing \( \text{Hom}^i(X, Y) \), we consider \( X, Y \) as elements in \( T = D^b(A) \), i.e. \( \text{Hom}^i(X, Y) = \text{Ext}^i(X, Y) \).

A \( \mathbb{K} \)-linear triangulated category \( T \) is called proper if \( \sum_{i \in \mathbb{Z}} \text{hom}^i(X, Y) < +\infty \) for any two objects \( X, Y \) in \( T \). For \( X, Y \in T \) in a proper \( T \), we denote:

\[
\text{hom}^{\text{min}}(X, Y) = \begin{cases} 
\text{hom}^i(X, Y) & \text{if } i = \min\{j : \text{hom}^j(X, Y) \neq 0\} > -\infty \\
0 & \text{otherwise}.
\end{cases}
\] (14)

We write \( \langle S \rangle \subset T \) for the triangulated subcategory of \( T \) generated by \( S \), when \( S \subset \text{Ob}(T) \).
An exceptional object in a $\mathbb{K}$-linear $\mathcal{T}$ is an object $E \in \mathcal{T}$ satisfying $\text{Hom}^i(E, E) = 0$ for $i \neq 0$ and $\text{Hom}(E, E) = k$.

An exceptional collection is a sequence $\mathcal{E} = (E_0, E_1, \ldots, E_n) \subset \mathcal{T}_{\text{exc}}$ satisfying $\text{hom}^*(E_i, E_j) = 0$ for $i > j$. If in addition we have $\langle \mathcal{E} \rangle = \mathcal{T}$, then $\mathcal{E}$ will be called a full exceptional collection.

If an exceptional collection $\mathcal{E} = (E_0, E_1, \ldots, E_n) \subset \mathcal{T}_{\text{exc}}$ satisfies $\text{hom}^k(E_i, E_j) = 0$ for any $i, j$ and for $k \neq 0$, then it is said to be strong exceptional collection.

An abelian category $\mathcal{A}$ is said to be hereditary, if $\text{Ext}^1(X, Y) = 0$ for any $X, Y \in \mathcal{A}$ and $i \geq 2$, it is said to be of finite length, if it is Artinian and Noetherian.

By $Q$ we denote an acyclic quiver and by $D^b(\text{Rep}_\mathbb{K}(Q))$, or just $D^b(Q)$, the derived category of the category of representations of $Q$.

For an integer $l \geq 1$ the $l$-Kronecker quiver (the quiver with two vertices and $l$ parallel arrows) will be denoted by $K(l)$.

For a complex number $z = (a + ib), a, b \in \mathbb{R}$ we denote $\Im(z) = b, \Re(z) = a$, and by $\mathcal{H}$ we denote the upper half plane, i.e. $\mathcal{H} = \{z \in \mathbb{C} : \Im(z) > 0\}$, whereas $\mathbb{H} = \mathcal{H} \cup \{z \in \mathbb{C} : \Im(z) = 0, \Re(z) < 0\}$. The number of elements of a finite set $X$ we denote by $|X|$ or by $\#(X)$.

### 3 On Bridgeland stability conditions

We use freely the axioms and notations on stability conditions introduced by Bridgeland in [10] and some additional notations used in [22, Subsection 3.2]. In particular, the underlying set of the manifold $\text{Stab}(\mathcal{T})$ is the set of locally finite stability conditions on $\mathcal{T}$ and for $\sigma = (Z, \mathcal{P}) \in \text{Stab}(\mathcal{T})$ we denote by $\sigma^{ss}$ the set of $\sigma$-semistable objects, i.e.

$$ \sigma^{ss} = \bigcup_{t \in \mathbb{R}} \mathcal{P}(t) \setminus \{0\}. $$

(15)

Also for a heart $\mathcal{A}$ of bounded t-structure in $\mathcal{T}$ we denote by $\mathbb{H}^\mathcal{A} \subset \text{Stab}(\mathcal{T})$ the subset of the stability conditions $(Z, \mathcal{P}) \in \text{Stab}(\mathcal{T})$ for which $\mathcal{P}(0, 1) = \mathcal{A}$ (see [21, Definition 2.28]).

Recall that one of Bridgeland’s axioms [10] is: for any nonzero $X \in \text{Ob}(\mathcal{T})$ there exists a diagram of distinguished triangles called Harder–Narasimhan filtration:

$$
\begin{array}{cccccc}
0 & \rightarrow & E_1 & \rightarrow & E_2 & \rightarrow \cdots & \rightarrow & E_{n-1} & \rightarrow & E_n = X \\
& & \downarrow A_1 & \swarrow A_2 & \downarrow & \cdots & \downarrow & \swarrow A_{n-1} & \downarrow A_n & \\
& & A_1 & \rightarrow & A_2 & \rightarrow & \cdots & \rightarrow & A_{n-1} & \rightarrow & A_n
\end{array}
$$

(16)

where $\{A_i \in \mathcal{P}(t_i)\}_{i=1}^n, t_1 > t_2 > \cdots > t_n$ and $A_i$ is non-zero object for any $i = 1, \ldots, n$ (the non-vanishing condition makes the factors $\{A_i \in \mathcal{P}(t_i)\}_{i=1}^n$ unique up to isomorphism). Following [10] we denote $\phi^-_\sigma(X) := t_n, \phi^+_\sigma(X) := t_1$, and the phase of a semistable object $A \in \mathcal{P}(t) \setminus \{0\}$ is denoted by $\phi_\sigma(A) := t$. The positive integer: $m_\sigma(X) = \sum_{i=1}^n \|Z(A_i)\|$ is called the mass of $X$ w.r. to $\sigma$ ([10, p.332]). We will use also the following axioms [10]:

$$ X \in \sigma^{ss} \Rightarrow Z(X) = m_\sigma(X) \exp(i\pi \phi_\sigma(X)), \quad m_\sigma(X) = |Z(X)| > 0 $$

(17)
\[ X, Y \in \sigma^s \quad \phi_\sigma(X) > \phi_\sigma(Y) \quad \Rightarrow \quad \text{Hom}(X, Y) = 0. \quad (18) \]

Finally we note that:

\[ m_\sigma(X) = m_\sigma(X_1) + m_\sigma(X_2) \]
\[ X \cong X_1 \oplus X_2 \quad \Rightarrow \quad \phi_\sigma(X) = \min\{\phi_\sigma(X_1), \phi_\sigma(X_2)\}, \]
\[ \phi_\sigma^+(X) = \max\{\phi_\sigma^+(X_1), \phi_\sigma^+(X_2)\} \quad (19) \]

which follows easily from the arguments for the proof of [21, Lemma 2.25].

### 3.1 Actions on Stab(\(\mathcal{T}\))

#### 3.1.1 The universal covering group of \(GL^+(2, \mathbb{R})\).

The universal covering group \(\tilde{GL}^+(2, \mathbb{R})\) of \(GL^+(2, \mathbb{R})\) can be constructed as follows (we point the steps without proving them). First step is to show that the following set with the specified below operations and metric is a topological group:

\[
\tilde{GL}^+(2, \mathbb{R}) = \left\{ (G, \psi) : G \in GL^+(2, \mathbb{R}), \psi \in C^\infty(\mathbb{R}) \right. \\
\left. \forall t \in \mathbb{R} \quad \psi'(t) > 0, \quad \psi(t + 1) = \psi(t) + 1, \quad \frac{G(\exp(i\pi t))}{[G(\exp(i\pi t))]} = \exp(i\pi \psi(t)) \right\}
\]

(20)

unit element: \((\text{Id}_\mathbb{C}, \text{Id}_\mathbb{R})\)

(21)
multiplication: \(((G_1, \psi_1), (G_2, \psi_2)) \mapsto (G_1 \circ G_2, \psi_1 \circ \psi_2)\)

(22)
inverse element: \((G, \psi) \mapsto (G^{-1}, \psi^{-1})\)

(23)
metric: \(d ((G_1, \psi_1), (G_2, \psi_2))\)

\[
= \sup_{t \in \mathbb{R}} |G_1(\exp(i\pi t)) - G_2(\exp(i\pi t))|, |\psi_1(t) - \psi_2(t)|.
\]

(24)

Second step is to show that the following is a covering map:

\[
\tilde{GL}^+(2, \mathbb{R}) \overset{\pi}{\to} GL^+(2, \mathbb{R}) \quad (G, \psi) \mapsto G.
\]

(25)

The subset \(U_\varepsilon = \{G \in GL^+(2, \mathbb{R}); \sup_{t \in \mathbb{R}} |G(\exp(i\pi t)) - \exp(i\pi t)| < \sin(\pi \varepsilon)\}\)

is evenly covered by a family of open subsets \((\{G, \psi); G \in U_\varepsilon \sup_{t \in \mathbb{R}} |\psi(t) - t - 2k| < \varepsilon\}\) indexed by \(k \in \mathbb{Z}\) for small enough \(\varepsilon\). In particular one obtains a structure or a Lie Group on \(\tilde{GL}^+(2, \mathbb{R})\) such that \(\pi\) is a morphism of Lie groups.

Finally, one can show that \(\tilde{GL}^+(2, \mathbb{R})\) is simply connected by recalling that \(\pi_1(GL^+(2, \mathbb{R})) \cong \mathbb{Z}\) is generated by \(S^1 = SO(2) \subset GL^+(2, \mathbb{R})\) and then by finding the lifts of this path in \(\tilde{GL}^+(2, \mathbb{R})\).

**Remark 3.1** For any \(0 < \varepsilon < 1, 0 < \varepsilon' < 1\) there exists unique \(g_{\varepsilon, \varepsilon'} = (G, \psi) \in \tilde{GL}^+(2, \mathbb{R})\) such that \(G^{-1}(1) = 1\) and \(G^{-1}(\exp(i\pi \varepsilon)) = \exp(i\pi \varepsilon')\) and \(\psi(0) = 0, \psi(1) = 1, \psi(\varepsilon') = \varepsilon\), in particular:

\(^5\) Neighborhood of \(\text{Id}_\mathbb{C} \in GL^+(2, \mathbb{R})\).
ψ([0, ε]) = [0, ε], ψ([ε, 1]) = [ε, 1] \tag{26}

Furthermore, \((g_{\epsilon, \epsilon'})^{-1} = g_{\epsilon', \epsilon}\).

The right action of \(\widetilde{GL}^+(2, \mathbb{R})\) on \(\text{Stab}(T)\) is defined by (recall [10]):

\[
\text{Stab}(T) \times \widetilde{GL}^+(2, \mathbb{R}) \to \text{Stab}(T) \quad ((Z, P), (G, \psi)) \mapsto (Z, P) \cdot (G, \psi) = (G^{-1} \circ Z, P \circ \psi). \tag{27}
\]

Using the formula (24) determining the topology on \(\widetilde{GL}^+(2, \mathbb{R})\) and the basis of the topology in \(\text{Stab}(T)\) explained on [10, p. 335] one can show that the function in (27) is continuous.

We recall also (see [10, Theorem 1.2]) that the projection \(\text{Stab}(T) \xrightarrow{proj} \text{Hom}(K_0(T), \mathbb{C}), proj(Z, P) = Z\) restricts to a local biholomorphism between each connected component of \(\text{Stab}(T)\) and a corresponding vector subspace of \(\text{Hom}(K_0(T), \mathbb{C})\) with a well defined linear topology (when \(\text{rank}(K_0(T)) < +\infty\) this is the ordinary linear topology). Note also that the results in [10] imply that \(\text{Stab}(T)\) is locally path connected (follows from the results in [10, Section 6] and [10, Theorem 7.1]), therefore the components and the path components of \(\text{Stab}(T)\) coincide and they are open subsets in \(\text{Stab}(T)\).

Finally, assume for simplicity that \(\text{rank}(K_0(T)) < +\infty\). Due to continuity of (27) it follows that for each connected component \(\Sigma\) of \(\text{Stab}(T)\) the action (27) restricts to a continuous action \(\Sigma \times \widetilde{GL}^+(2, \mathbb{R}) \to \Sigma\) and it is easy to show that there is a commutative diagram:

\[
\begin{array}{ccc}
\Sigma \times \widetilde{GL}^+(2, \mathbb{R}) & \longrightarrow & \Sigma \\
proj \times \pi \downarrow & & \downarrow proj \\
V(\Sigma) \times GL^+(2, \mathbb{R}) & \longrightarrow & V(\Sigma)
\end{array} \tag{28}
\]

where \(V(\Sigma) \subset \text{Hom}(K_0(T), \mathbb{C})\) is the corresponding to \(\Sigma\) vector subspace, such that the vertical arrows are local diffeomorphisms (the right arrow is local biholomorphism), and the lower horizontal arrow is an action of the form \((A, G) \mapsto A \circ G^{-1}\) on \(V(\Sigma)\). Now it follows that the upper horizontal arrow is smooth, and therefore (27) is smooth as well.

### 3.1.2 The action of \(\mathbb{C}\)

There is a Lie group homomorphism \(\mathbb{C} \to \widetilde{GL}^+(2, \mathbb{R})\) given by \(\lambda \mapsto \left(e^{-\lambda}, \text{Id}_\mathbb{R}, -\frac{\lambda}{\pi}\right)\). And composing the action (27) with this homomorphism results in the action (29) below. This action is free [34, Definition 2.3, Proposition 4.1]. It is easy to show that for any \(X \in T, \sigma \in \text{Stab}(T), z \in \mathbb{C}\) hold the properties in (30), (31) below, and the HN filtrations of \(X\) w.r. to \(\sigma\) and to \(z \circ \sigma\) are the same:

\[
\mathbb{C} \times \text{Stab}(T) \xrightarrow{\star} \text{Stab}(T) \quad z \star (Z, \{P(t)\}_t \in \mathbb{R}) = \left(e^z Z, \{P(t - \Im(z)/\pi)\}_t \in \mathbb{R}\right) \tag{29}
\]
\[(z \star \sigma)^{ss} = \sigma^{ss} \phi_{z \star \sigma}(X) = \phi_{\sigma}(X) + \Im(z)/\pi \quad X \in \sigma^{ss}\]
\[\phi_{z \star \sigma}^{\pm}(X) = \phi_{\sigma}^{\pm}(X) + \Im(z)/\pi; \quad m_{z \star \sigma}(X) = e^{\Im(z)} m_{\sigma}(X).\]  

4 Triangulated categories with phase gaps and their norms

4.1 Full stability conditions

We start this section by recalling what is meant when saying that a stability condition is full.

*Full stability condition* on $K3$ surface is defined in [10, Definition 4.2]. Analogous definition can be given for any triangulated category $\mathcal{T}$ and locally finite stability condition whose central charge factors through a given group homomorphism $ch : K_0(\mathcal{T}) \to \mathbb{Z}^n$.

When $K_0(\mathcal{T})$ has finite rank, we choose always the trivial homomorphism $K_0(\mathcal{T}) \to K_0(\mathcal{T})$. Now the projection $\text{Stab}(\mathcal{T}) \xrightarrow{\text{proj}} \text{Hom}(K_0(\mathcal{T}), \mathbb{C})$, $\text{proj}(Z, \mathcal{P}) = Z$ restricts to a local biholomorphism between each connected component of $\text{Stab}(\mathcal{T})$ and a corresponding vector subspace of $\text{Hom}(K_0(\mathcal{T}), \mathbb{C})$ (see [10, Theorem 1.2]). A stability condition $\sigma \in \text{Stab}(\mathcal{T})$ in this case is a full stability condition, if the vector subspace of $\text{Hom}(K_0(\mathcal{T}), \mathbb{C})$ corresponding to the connected component $\Sigma_1$ containing $\sigma$ is the entire $\text{Hom}(K_0(\mathcal{T}), \mathbb{C})$, which is equivalent to the equality $\dim_{\mathbb{C}}(\Sigma_1) = \text{rank}(K_0(\mathcal{T}))$.

As we will see later all stability conditions on $K(l)$ are full, for all $l \geq 1$ (see table (10)). It is reasonable to hope that, whenever $\text{Stab}(\mathcal{T}) \neq \emptyset$, there are always full stability conditions on $\mathcal{T}$ and, to the best of our knowledge, there are no counterexamples of this statement so far.

4.2 The $\varepsilon$-norm of a triangulated category

Recall that for $\sigma = (Z, \mathcal{P}) \in \text{Stab}(\mathcal{T})$ we denote (see [18, Section 3]):

\[P_{\sigma}^T = \{\exp(i\pi \phi_{\sigma}(X)) : X \in \sigma^{ss}\} = \{\exp(i\pi t) : t \in \mathbb{R} \text{ and } \mathcal{P}(t) \neq \{0\}\},\]  
(32)

Here we will use also the notation:

\[\tilde{P}_{\sigma}^T = \{t \in \mathbb{R} : \mathcal{P}(t) \neq \{0\}\} \Rightarrow P_{\sigma}^T = \exp\left(i\pi \tilde{P}_{\sigma}^T\right).\]  
(33)

The sets $P_{\sigma}^T$ and $\tilde{P}_{\sigma}^T$ satisfy $P_{\sigma}^T = -P_{\sigma}^T$, $\tilde{P}_{\sigma}^T + 1 = \tilde{P}_{\sigma}^T$. In particular the closures $\overline{P_{\sigma}^T}$, $\overline{\tilde{P}_{\sigma}^T}$ satisfy:

\[\text{vol}(\overline{P_{\sigma}^T}) = 2\pi \mu(\overline{P_{\sigma}^T} \cap [0, 1]) = 2\pi \int_{[0,1] \cap P_{\sigma}} d\mu.\]  
(34)
where \( \mu \) is the Lebesgue measure in \( \mathbb{R} \) and \( \text{vol} \) is the corresponding measure in \( S^1 \) with \( \text{vol}(S^1) = 2\pi \). Due to (27), (30), for any \( z \in \mathbb{C} \), any \( g = (G, \psi) \in \widetilde{GL}^+ (2, \mathbb{R}) \), and any \( \sigma \in \text{Stab}(T) \) we have:

\[
P^T_{z*\sigma} = \exp(i\Im(z)) P^T_{\sigma} \quad \widehat{P}^T_{\sigma \cdot g} = \psi^{-1} \left( \widehat{P}^T_{\sigma} \right).
\]  

(35)

**Definition 4.1** Let \( 0 < \varepsilon < 1 \). Any subset of \( S^1 \) of the form \( \exp(i\pi [a, a + \varepsilon]) \), where \( a \in \mathbb{R} \) will be referred to as a **closed \( \varepsilon \)-arc** in \( S^1 \).

**Remark 4.2** The action of \( \text{Aut}(T) \) on \( \text{Stab}(T) \) was recalled in the end of the previous section. Following this definition one defines straightforwardly a biholomorphism \( [F] : \text{Stab}(T_1) \to \text{Stab}(T_2) \) for any equivalence \( F \) between triangulated categories \( T_1 \) and \( T_2 \) satisfying \( P^T_{[F](\sigma)} = P^T_{\sigma} \) for each \( \sigma \in \text{Stab}(T_1) \).

In Definition 4.11 we will use the following subset of the set of stability conditions:

**Definition 4.3** For any \( 0 < \varepsilon < 1 \) and any triangulated category \( T \) we denote:

\[
\text{Stab}_\varepsilon(T) = \{ \sigma \in \text{Stab}(T) : \sigma \text{ is full and } S^1 \setminus P^T_{\sigma} \text{ contains a closed } \varepsilon \text{ arc} \}
\]

\[
\text{Stab}_{[a, a + \varepsilon]}(T) = \{ \sigma \in \text{Stab}(T) : \sigma \text{ is full and } \widehat{P}^T_{\sigma} \cap [a, a + \varepsilon] = \emptyset \}.
\]

It is obvious that (recall also 35):

\[
\text{Stab}_\varepsilon(T) = \bigcup_{a \in \mathbb{R}} \text{Stab}_{[a, a + \varepsilon]}(T) = \mathbb{C} \ast \text{Stab}_{[0, \varepsilon]}(T)
\]  

(36)

The next simple observation is:

**Lemma 4.4** Let \( g_{\varepsilon, \varepsilon'} \in \widetilde{GL}^+ (2, \mathbb{R}) \) be as in Remark 3.1. For any \( 0 < \varepsilon < 1, 0 < \varepsilon' < 1 \) holds:

\[
\text{Stab}_{[0, \varepsilon]}(T) \cdot g_{\varepsilon, \varepsilon'} = \text{Stab}_{[0, \varepsilon']} (T).
\]  

(37)

**Proof** Using (35), (26), and the fact that \( \psi \) is diffeomorphism we compute

\[
\widehat{P}^T_{(\sigma; g_{\varepsilon, \varepsilon'})} \cap [0, \varepsilon'] = \psi^{-1} \left( \widehat{P}^T_{\sigma} \cap \psi^{-1} ([0, \varepsilon]) \right) = \psi^{-1} \left( \widehat{P}^T_{\sigma} \cap [0, \varepsilon] \right).
\]

Now the lemma follows from the very Definition 4.3 and the property \( g_{\varepsilon, \varepsilon'}^{-1} = g_{\varepsilon', \varepsilon} \).

**Corollary 4.5** Let \( T \) be any triangulated category. The following are equivalent:

(a) \( \text{Stab}_\varepsilon(T) \neq \emptyset \) for some \( \varepsilon \in (0, 1) \)

(b) \( \text{Stab}_\varepsilon(T) \neq \emptyset \) for each \( \varepsilon \in (0, 1) \)

(c) \( P^T_{\sigma} \) is not dense in \( S^1 \) for some full \( \sigma \in \text{Stab}(T) \).

**Proof** (a) \( \Rightarrow \) (b). Follows from (36) and Lemma 4.4.
(b) $\Rightarrow$ (c). It is obvious from the definitions that for any $0 < \epsilon < 1$ and any $\sigma \in \text{Stab}_e(T)$ the set $P_{\sigma}^T$ is not dense in $\mathbb{S}^1$.

(c) $\Rightarrow$ (a). If $P_{\sigma}^T$ is not dense, then $\mathbb{S}^1 \setminus P_{\sigma}^T$ contains an open arc, but then it contains a closed arc as well and then $\sigma \in \text{Stab}_e(T)$ for some $\epsilon \in (0, 1)$.

\[ \square \]

**Definition 4.6** A triangulated category $\mathcal{T}$ will be called a category with phase gap if $P_{\sigma}^T$ is not dense in $\mathbb{S}^1$ for some full $\sigma \in \text{Stab}(T)$ (by Corollary 4.5 then $\text{Stab}_e(T)$ is not empty for any $0 < \epsilon < 1$).

**Lemma 4.7** If $K_0(T)$ has finite rank, then $\mathcal{T}$ has a phase gap iff there exists a bounded t-structure in $\mathcal{T}$ whose heart is of finite length and has finitely many simple objects.

**Proof** Let $\mathcal{A}$ be such a heart and let $s_1, s_2, \ldots, s_n$ be the simple objects in $\mathcal{A}$. Under the given assumptions $K_0(T) \cong K_0(\mathcal{A}) \cong \mathbb{Z}^n$. [10, Proposition 2.4, Proposition 5.3] imply that for any sequence of vectors $z_1, z_2, \ldots, z_n$ in $\mathbb{H}$ there exists unique stability condition $\sigma = (Z, P)$ with $P(0, 1] = \mathcal{A}$ and $Z(s_i) = z_i, i = 1, \ldots, n$. For this $\sigma$ we have $Z(P(0, 1] \setminus \{0\}) = \{ \sum_{i=1}^n a_i z_i : (a_1, a_2, \ldots, a_n) \in \mathbb{N}^n \setminus \{0\} \}$ and therefore $Z(\sigma^{ss}) \subset \pm \{ \sum_{i=1}^n a_i z_i : (a_1, a_2, \ldots, a_n) \in \mathbb{N}^n \setminus \{0\} \}$, now from [16, Lemma 1.1] it follows that $\sigma$ is locally finite. Recall that we denote by $\mathbb{H}^A \subset \text{Stab}(T)$ the subset of the stability conditions $(Z, P) \in \text{Stab}(T)$ for which $P(0, 1] = \mathcal{A}$ (see after 15). So far we constructed $\sigma \in \mathbb{H}^A$ determined uniquely by any sequence $z_1, z_2, \ldots, z_n$ in $\mathbb{H}$. Varying the vector $(z_1, z_2, \ldots, z_n) \in \mathbb{H}^n$ we obtain a biholomorphism between $\mathbb{H}^n$ and the subset $\mathbb{H}^A \subset \text{Stab}(T)$. In particular the stability conditions in $\mathbb{H}^A$ are full. Since for $\sigma \in \mathbb{H}^A$ corresponding to a sequence $z_1, z_2, \ldots, z_n$ in $\mathbb{H}$ holds $Z(\sigma^{ss}) \subset \pm \{ \sum_{i=1}^n a_i z_i : (a_1, a_2, \ldots, a_n) \in \mathbb{N}^n \setminus \{0\} \}$, it follows that $Z(\sigma^{ss}) \subset \pm \{ x \exp(i \pi a) + y \exp(i \pi (a + 1 - \epsilon)) : x, y \in (0, +\infty) \}$ for some $a \in \mathbb{R}$ and some $0 < \epsilon < 1$, therefore by (17) $\mathbb{S}^1 \setminus P_{\sigma}^T$ contains a closed $\epsilon$ arc, hence $\sigma \in \text{Stab}_e(T)$, and hence $\mathcal{T}$ has a phase gap (recall Definitions 4.3, 4.6).

Conversely, let $\sigma' = (Z, P) \in \text{Stab}_e(T)$. By definition $\sigma'$ is a full stability condition. Due to (36), we can choose $\lambda \in \mathbb{C}$, so that the stability condition $\sigma = \lambda*\sigma'$ satisfies $P_\sigma(t) = \{0\}$ for $t \in [0, \epsilon]$ and $P_\sigma(0, 1] = P_\sigma(\epsilon/2, 1]$. From [11, Lemma 4.5] it follows that $P_\sigma(0, 1] = P_\sigma(\epsilon/2, 1]$ is a finite length quasi-abelian category (here the property of $\sigma$ being full is used), and since $\sigma$ is a stability condition, $P_\sigma(0, 1]$ is a heart of a bounded t-structure. Therefore $P_\sigma(0, 1]$ is a finite length abelian category whose simple objects are a basis of $K_0(T)$, in particular the simple objects are finitely many.

\[ \square \]

**Remark 4.8** The elements $\sigma \in \text{Stab}(T)$ for which $P(0, 1]$ is of finite length and with finitely many simple objects are called algebraic stability conditions and have been discussed extensively in [37].

**Remark 4.9** In [12] they define a quiver with potential starting with a triangulation of a compact closed surface with marked points. The full subcategory of the derived category of the complete Ginzburg algebra of this quiver consisting of modules with finite-dimensional cohomology is a CY3 category. Due to (i), (ii) in [12, Subsection 7.1] and Lemma 4.7 CY3 categories obtained by this procedure have phase gaps.
Remark 4.10 Let $T$ be proper and with a full exceptional collection. [22, Remark 3.20] and Corollary 4.5 imply that $\text{Stab}_\varepsilon(T) \neq \emptyset$ for any $0 < \varepsilon < 1$, i.e. $T$ is a category with a phase gap.

The main definition of this section is:

Definition 4.11 Let $T$ be a triangulated category with phase gap. Let $0 < \varepsilon < 1$. We define:

$$\|T\|_\varepsilon = \sup \left\{ \frac{1}{2} \text{vol} \left( \overline{P_\sigma} \right) : \sigma \in \text{Stab}_\varepsilon(T) \right\}.$$ (38)

Remark 4.12 For a category $T$ which carries a full stability condition, but has no phase gap (i.e. $P_T^\sigma$ is dense in $S^1$ for all full stability conditions $\sigma$) it seems reasonable to define $\|T\|_\varepsilon = \pi(1 - \varepsilon)$, but we will restrict our attention to categories with phase gaps in the rest.

In remarks 4.13, 4.14 $\varepsilon$ and $T$ are as in Definition 4.11.

Remark 4.13 Using (34), (35), (36) one shows that ($\mu$ is the Lebesgue measure of $\mathbb{R}$):

$$\|T\|_\varepsilon = \sup \left\{ \pi \mu \left( [\varepsilon, 1] \cap \overline{P_\sigma} \right) : \sigma \in \text{Stab}_{[0,\varepsilon]}(T) \right\}.$$ (39)

Remark 4.14 We have always $0 \leq \|T\|_\varepsilon \leq \pi(1 - \varepsilon)$.

Remark 4.15 Using Remark 4.2 we see that if $T_1$, $T_2$ are equivalent triangulated categories with finite rank Grothendieck groups, then for any $0 < \varepsilon < 1$ holds $\|T_1\|_\varepsilon = \|T_2\|_\varepsilon$.

Lemma 4.16 Let $\varepsilon, \varepsilon'$ be any two numbers in $(0, 1)$.

(a) There exist $0 < m < M$ such that $m \|T\|_\varepsilon \leq \|T\|_{\varepsilon'} \leq M \|T\|_\varepsilon$ for any category with a phase gap $T$. In particular, for any category with a phase gap $T$ we have: $\|T\|_\varepsilon = 0 \iff \|T\|_{\varepsilon'} = 0$.

(b) For any category with a phase gap $T$ we have $\|T\|_\varepsilon = \pi(1 - \varepsilon) \iff \|T\|_{\varepsilon'} = \pi(1 - \varepsilon')$.

Proof We will use the element $g_{\varepsilon, \varepsilon'} = (G, \psi) \in \widehat{GL}(2, \mathbb{R})$ from Remark 3.1. In particular the function $\psi \in C^\infty(\mathbb{R})$ restricts to a diffeomorphism $\psi : [\varepsilon', 1] \to [\varepsilon, 1]$. Let us denote the inverse function by $\kappa$, then we choose $m, M \in \mathbb{R}$ as follows:

$$\psi^{-1} = \kappa : [\varepsilon, 1] \to [\varepsilon', 1] \ \forall t \in [\varepsilon, 1] \ 0 < m \leq \kappa'(t) \leq M.$$ (40)

With the help of [39, formula (15) on page 156], we see that for any Lebesgue measurable subset $A \subset [\varepsilon, 1]$ holds (for a subset $E \subset [\varepsilon', 1]$ or $E \subset [\varepsilon, 1]$ we denote by $\chi_E$ the function equal to 1 at the points of $E$ and 0 elsewhere):

$$\mu(A) = \int_{\varepsilon'}^1 \chi_{\kappa(A)}(t) dt = \int_{\varepsilon}^1 \chi_{\kappa(A)}(\kappa(t))\kappa'(t) dt = \int_{\varepsilon}^1 \chi_A(t)\kappa'(t) dt$$
which by (40) implies:

$$m \mu (A) \leq \mu (\kappa (A)) \leq M \mu (A).$$  \hspace{1cm} (41)

Using Remark 4.13, Lemma 4.4, and the second equality in (35) we get:

$$\|T\|_{\varepsilon} / \pi = \sup \left\{ \mu \left( [\varepsilon, 1] \cap \overline{P_{\sigma}} \right) : \sigma \in \text{Stab}_{[0, \varepsilon]}(T) \right\} \hspace{1cm} (42)$$

$$\|T\|_{\varepsilon'} / \pi = \sup \left\{ \mu \left( \kappa \left( [\varepsilon, 1] \cap \overline{P_{\sigma}} \right) \right) : \sigma \in \text{Stab}_{[0, \varepsilon]}(T) \right\}. \hspace{1cm} (43)$$

Now (a) follows from (41), (42), (43).

(b) Let \(\|T\|_{\varepsilon} = \pi (1 - \varepsilon)\) and \(\delta > 0\). We will prove that (43) equals \((1 - \varepsilon')\) by finding \(\sigma \in \text{Stab}_{[0, \varepsilon]}(T)\) such that \(\mu \left( \kappa \left( [\varepsilon, 1] \cap \overline{P_{\sigma}} \right) \right) > 1 - \varepsilon' - \delta.\) Since

\[1 - \varepsilon' = \mu([\varepsilon', 1]) = \mu \left( \kappa \left( [\varepsilon, 1] \cap \overline{P_{\sigma}} \right) \right) + \mu \left( \kappa \left( [\varepsilon, 1] \setminus \overline{P_{\sigma}} \right) \right),\]

we need to find \(\sigma \in \text{Stab}_{[0, \varepsilon]}(T)\) such that:

$$\mu \left( \kappa \left( [\varepsilon, 1] \setminus \overline{P_{\sigma}} \right) \right) < \delta. \hspace{1cm} (44)$$

Since \(\|T\|_{\varepsilon} = \pi (1 - \varepsilon)\), (42) ensures that there is \(\sigma \in \text{Stab}_{[0, \varepsilon]}(T)\) such that

\[\mu \left( [\varepsilon, 1] \cap \overline{P_{\sigma}} \right) > 1 - \varepsilon - \frac{\delta}{M},\]

which due to the equality \(\mu \left( [\varepsilon, 1] \cap \overline{P_{\sigma}} \right) + \mu \left( [\varepsilon, 1] \setminus \overline{P_{\sigma}} \right) = 1 - \varepsilon\) is the same as \(\mu \left( [\varepsilon, 1] \setminus \overline{P_{\sigma}} \right) < \frac{\delta}{M}.\) We combine (41) and the latter inequality to deduce the desired (44):

$$\mu \left( \kappa \left( [\varepsilon, 1] \setminus \overline{P_{\sigma}} \right) \right) \leq M \mu \left( [\varepsilon, 1] \setminus \overline{P_{\sigma}} \right) < \delta. \hspace{1cm} \square$$

[18, Corollary 3.28] (see [21, Corollary 3.25] for any algebraically closed field \(\mathbb{K}\)) amounts to the following criteria for non-vanishing of \(\|T\|_{\varepsilon}\):

**Proposition 4.17** Let \((E_0, E_1, \ldots, E_n)\) be a full exceptional collection in a \(\mathbb{K}\)-linear proper triangulated category \(\mathcal{D}\). If for some \(i\) the pair \((E_i, E_{i+1})\) satisfies \(\text{hom}^1(E_i, E_{i+1}) \geq 3\) and \(\text{hom}^0(E_i, E_{i+1}) = 0\), then \(\|\mathcal{D}\|_{\varepsilon} > 0\).

**Corollary 4.18** Let \(\varepsilon \in (0, 1)\). Then:

(a) If \(Q\) is an acyclic quiver, which is neither Dynkin nor affine, then \(\|D^b(Q)\|_{\varepsilon} > 0\).

(b) \(\|D^b(\text{coh}(X))\|_{\varepsilon} > 0\), where \(X\) is a smooth projective variety over \(\mathbb{C}\), such that \(D^b(\text{coh}(X))\) is generated by a strong exceptional collection of three elements

**Proof** (a) Follows from the previous proposition, [18, Proposition 3.34], and the fact that each exceptional collection in \(D^b(Q)\) can be extended to a full exceptional collection (see [17]).

(b) It follows from proposition 4.17 and [18, 3.5.1].

\(\square\)

In Sect. 8 we will refine Proposition 4.17, which will help us to prove that \(\|D^b(\text{coh}(X))\|_{\varepsilon} = \pi (1 - \varepsilon)\) if \(X\) is \(\mathbb{P}^1 \times \mathbb{P}^1, \mathbb{P}^n\) with \(n \geq 2\) or some of these blown up in finite number of points.
Proposition 4.19 Let $\varepsilon \in (0, 1)$. For acyclic quiver $Q$ we have $\|D^b(Q)\|_{\varepsilon} = 0$ iff $Q$ is affine or Dynkin. In particular $\|D^b(\text{coh}(\mathbb{P}^1))\|_{\varepsilon} = 0$.

**Proof** If $Q$ is affine or Dynkin, then from the first and the second rows of table (9) we see that vol $\{T_i\} = 0$ for any $\sigma \in \text{Stab}(D^b(Q))$, therefore $\|D^b(Q)\|_{\varepsilon} = 0$, and in Corollary 4.18 we showed that $\|D^b(Q)\|_{\varepsilon} > 0$ for the rest quivers. $\square$

5 Stability conditions on orthogonal decompositions

First we recall the definition of a semi-orthogonal, resp. orthogonal, decomposition of a triangulated category:

**Definition 5.1** If $\mathcal{T}$ is a triangulated category, $\mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n$ are triangulated subcategories in it satisfying the equalities $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ and Hom($\mathcal{T}_j, \mathcal{T}_i$) = 0 for $j > i$, then we say that $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ is a semi-orthogonal decomposition. If in addition holds Hom($\mathcal{T}_i, \mathcal{T}_j$) = 0 for $i < j$, then we say that $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ is an orthogonal decomposition, in which case we will write sometimes $\mathcal{T} = \mathcal{T}_1 \oplus \mathcal{T}_2 \oplus \cdots \oplus \mathcal{T}_n$. Obviously, if $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ is an orthogonal decomposition, then $\mathcal{T} = \langle \mathcal{T}_{s(1)}, \mathcal{T}_{s(2)}, \ldots, \mathcal{T}_{s(n)} \rangle$ is an orthogonal decomposition for any permutation $s : \{1, \ldots, n\} \rightarrow \{1, \ldots, n\}$.

**Proposition 5.2** Let $\mathcal{T} = \langle \mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n \rangle$ be any orthogonal decomposition. Let $K_0(\mathcal{T}_i) \xrightarrow{i_n} K_0(\mathcal{T}) \xrightarrow{p_rj} K_0(\mathcal{T}_j), \ 1 \leq i, j \leq n$ be the natural biproduct diagram. Then:

(a) The following map is a bijection:

$$\text{Stab}(\mathcal{T}) \rightarrow \text{Stab}(\mathcal{T}_1) \times \text{Stab}(\mathcal{T}_2) \times \cdots \times \text{Stab}(\mathcal{T}_n)$$

(45)

$$(Z, [P(t)]_{t \in \mathbb{R}}) \mapsto ((Z \circ p_r1, [P(t) \cap \mathcal{T}_1]_{t \in \mathbb{R}}),$$

$$\ldots, (Z \circ p_rn, [P(t) \cap \mathcal{T}_n]_{t \in \mathbb{R}})).$$

(46)

(b) For any $(Z, [P(t)]_{t \in \mathbb{R}}) \in \text{Stab}(\mathcal{T})$ and any $t \in \mathbb{R}$ the subcategory $P(t)$ is non-trivial iff for some $j$ $P(t) \cap \mathcal{T}_j$ is non-trivial.

(c) If rank($K_0(\mathcal{T}_i)$) < $+\infty$ for all $i = 1, 2, \ldots, n$, then the map defined above is biholomorphism.

(d) For each $\sigma \in \text{Stab}(\mathcal{T})$ holds $P^T_\sigma = \cup_{i=1}^n P^T_{\sigma_i}$, where $(\sigma_1, \ldots, \sigma_n)$ is the value of (45) at $\sigma$.

**Proof** We will give all details for the proof of (a), (b), (c) in the case $n = 2$. The general case follows easily by induction. (d) follows from the very definition (32) and (a), (b).

It is well known that for each $X \in \mathcal{T}$ there exists unique up to isomorphism triangle $E_2 \rightarrow X \rightarrow E_1 \rightarrow E_2[1]$ with $E_i \in \mathcal{T}_i, i = 1, 2$. By Hom($\mathcal{T}_1, \mathcal{T}_2$) = 0 it follows that each of these triangles is actually part of a direct product diagram and $pr_i([X]) = [E_i]$ for $i = 1, 2$. 
Now let \( X \in \mathcal{T}_1 \) and \( U \to X \to B \to U[1] \) be a triangle in \( T \). Using \( \text{Hom}(\mathcal{T}_2, \mathcal{T}_1) = \text{Hom}(\mathcal{T}_1, \mathcal{T}_2) = 0 \) and decomposing \( U \) into direct summands \( U_1 \oplus U_2 \) with \( U_i \in \mathcal{T}_i \) one easily concludes that the triangle \( U \to X \to B \to U[1] \) is isomorphic to a triangle of the form \( U_1 \oplus U_2 \to X \to B' \oplus U_2[1] \to U_1[1] \oplus U_2[1] \). If we apply these arguments to the last triangle in (16) and using that \( \text{hom}(E_{n-1}, A_n[i]) = 0 \) for \( i \leq 0 \), we immediately obtain \( E_{n-1} \). After \( \mathcal{T}_1 \) and then by induction it follows that the entire HN filtration of \( X \) lies in \( \mathcal{T}_1 \), in particular \( A_i \in \mathcal{P}(t_i) \cap \mathcal{T}_i \) for \( i = 1, 2, \ldots, n \), furthermore we have \( Z_1([X]) = Z(pr_1([X])) \) for each \( X \in \mathcal{P}(t) \cap \mathcal{T}_1 \) and now it is obvious that \((Z \circ pr_1, \{ \mathcal{P}(t) \cap \mathcal{T}_1 \}_{t \in \mathbb{R}}) = (Z_1, \mathcal{P}_1)\) is a stability condition on \( \mathcal{T}_1 \).

The same arguments as in the previous paragraph apply to the case \( X \in \mathcal{T}_2 \) and show that \((Z \circ pr_2, \{ \mathcal{P}(t) \cap \mathcal{T}_2 \}_{t \in \mathbb{R}}) = (Z_2, \mathcal{P}_2)\) is a stability condition on \( \mathcal{T}_2 \). We will show that \( \sigma_i \) are locally finite for \( i = 1, 2 \).

Indeed, since \( \sigma \) is locally finite stability condition on \( T \), then there exists \( \frac{1}{n} > \varepsilon > 0 \) such that \( \mathcal{P}(t-\varepsilon, t+\varepsilon) \) is quasi-abelian category of finite length for each \( t \in \mathbb{R} \).

One easily shows that \( \mathcal{P}(t-\varepsilon, t+\varepsilon) = \mathcal{T}_i \cap \mathcal{P}(t-\varepsilon, t+\varepsilon) \) for each \( t \). From [10, Lemma 4.3] we know that a sequence \( A \to B \to C \) in \( \mathcal{P}(t-\varepsilon, t+\varepsilon) \) is a strict short exact sequence iff it is a triangle \( A \to B \to C \to A[1] \). Since for \( A, B, C \in \mathcal{T}_i \) \( A \to B \to C \to A[1] \) is triangle in \( \mathcal{T}_i \) iff it is a triangle in \( T \), we deduce that for \( A, B, C \in \mathcal{P}(t-\varepsilon, t+\varepsilon) \) \( A \to B \to C \) is a strict exact sequence in \( \mathcal{P}(t-\varepsilon, t+\varepsilon) \) iff it is a strict exact sequence in \( \mathcal{P}(t-\varepsilon, t+\varepsilon) \), and now from the fact that \( \mathcal{P}(t-\varepsilon, t+\varepsilon) \) is of finite length it follows that \( \mathcal{P}(t-\varepsilon, t+\varepsilon) \) is of finite length and \( \sigma_i \in \text{Stab}(\mathcal{T}_i) \) for \( i = 1, 2 \).

So far we showed that the map is well defined. Since for any interval \( I \subset \mathbb{R} \) the subcategory \( \mathcal{P}(I) \) is thick (see e.g. [21, Lemma 2.20.]), it follows that \( \mathcal{P}(t) = \mathcal{P}(t) \cap \mathcal{P}_1(t) \) for each \( t \in \mathbb{R} \) and hence follows the injectivity of the map. Furthermore, using the terminology of [16, Definition before Proposition 2.2] we see that \( \sigma \) is glued from \( \sigma_1 \) and \( \sigma_2 \). From the given arguments it follows also that for \( X \in \mathcal{T}_i \) the HN filtrations w.r. to \( \sigma \) and w.r. to \( \sigma_i \) coincide, in particular:

\[
X \in \mathcal{T}_i \Rightarrow \phi_{\sigma_i}^+(X) = \phi_{\sigma}^+(X) \quad m_{\sigma_i}(X) = m_{\sigma}(X) \tag{47}
\]

on the other hand any \( X \in \mathcal{T} \) can be represented uniquely (up to isomorphism) as a biproduct \( X \cong X_1 \oplus X_2 \) with \( X_i \in \mathcal{T}_i \) for \( i = 1, 2 \) and (19) imply:

\[
m_{\sigma}(X) = m_{\sigma_1}(X_1) + m_{\sigma_2}(X_2) \quad \forall X \in \mathcal{T} \Rightarrow X \cong X_1 \oplus X_2, \quad X_i \in \mathcal{T}_i \Rightarrow \phi_{\sigma_i}^-(X) = \min\{\phi_{\sigma_1}^-(X_1), \phi_{\sigma_2}^-(X_2)\} \quad m_{\sigma}(X) = m_{\sigma_1}(X_1) + m_{\sigma_2}(X_2) \tag{48}
\]

Conversely, if \((\sigma_1, \sigma_2) \in \text{Stab}(\mathcal{T}_1) \times \text{Stab}(\mathcal{T}_2)\), then [16, Proposition 3.5] ensures existence of a locally finite stability condition \( \sigma \in \text{Stab}(\mathcal{T}) \) glued from \( \sigma_1, \sigma_2 \) and using [16, (3) in Proposition 2.2]) one easily shows that our map sends the glued \( \sigma \) to the pair \((\sigma_1, \sigma_2)\), hence the surjectivity of the map follows.

Now we will show that if \( rank(K_0(\mathcal{T}_i)) < +\infty \) for \( i = 1, 2 \), then the map defined above is biholomorphism. First we show that it is continuous.

[10, Proposition 8.1.] says that for any triangulated category \( T \) assigning to any two \( \sigma_1, \sigma_2 \in \text{Stab}(T) \) the following:
Lemma 5.3
For any positive real numbers $x, y$ holds the inequality:

$$\log \frac{x_1 + x_2}{y_1 + y_2} \leq \log \frac{x_1}{y_1} + \log \frac{x_2}{y_2}.$$  

Proof We can assume that $\frac{x_1 + x_2}{y_1 + y_2} \geq 1$ (otherwise take $\frac{y_1 + y_2}{x_1 + x_2}$). Now we consider three cases:

If $\frac{x_1}{y_1} \geq 1$ and $\frac{x_2}{y_2} \geq 1$, then the desired inequality becomes

$$\log \frac{x_1 + x_2}{y_1 + y_2} \leq \log \frac{x_1}{y_1} + \log \frac{x_2}{y_2},$$

which after exponentiating is equivalent to

$$\frac{x_1 + x_2}{y_1 + y_2} \leq \frac{x_1x_2}{y_1y_2} \iff (x_1 + x_2)y_1y_2 \leq x_1x_2(y_1 + y_2) \iff 0 \leq x_1y_1(x_2 - y_2) + x_2y_2(x_1 - y_1)$$

the latter inequality follows from $x_1 \geq y_1, x_2 \geq y_2$. 

The first (50) follows easily from (47). The second requires a bit more computations, which we will present partly. Take any $X \in \mathcal{T}$ and decompose it $X \cong X_1 \oplus X_2$, $X_i \in \mathcal{T}_i$, then from (48) we see that

$$\max\{d_1(\sigma, \sigma'), d_2(\sigma_2, \sigma'_2)\} \leq d(\sigma, \sigma') \tag{50}$$

$$d(\sigma, \sigma') \leq d_1(\sigma, \sigma'_1) + d_2(\sigma_2, \sigma'_2) \tag{51}$$

where we used, besides the definition of the generalized metrics (49), the following lemma:

**Lemma 5.3** For any positive real numbers $x_1, x_2, y_1, y_2$ holds the inequality:

$$\log \frac{x_1 + x_2}{y_1 + y_2} \leq \log \frac{x_1}{y_1} + \log \frac{x_2}{y_2}.$$
If \( \frac{x_1}{y_1} \leq 1 \) and \( \frac{x_2}{y_2} \geq 1 \), then the desired inequality becomes \( \log \frac{x_1 + x_2}{y_1 + y_2} \leq \log \frac{y_1}{x_1} + \log \frac{x_2}{y_2} \) which after exponentiating is equivalent to

\[
\frac{x_1 + x_2}{y_1 + y_2} \leq \frac{y_1 x_2}{x_1 y_2} \iff (x_1 + x_2)x_1 y_2 \leq y_1 x_2 (y_1 + y_2)
\]

\[
\iff 0 \leq y_1^2 x_2 - x_1^2 y_2 + x_2 y_2 (y_1 - x_1)
\]

the latter inequality follows from \( y_1 \geq x_1, x_2 \geq y_2 \).

If \( \frac{x_1}{y_1} \leq 1 \) and \( \frac{x_2}{y_2} \leq 1 \), then the desired inequality becomes \( \log \frac{x_1 + x_2}{y_1 + y_2} \leq \log \frac{y_1}{x_1} + \log \frac{x_2}{y_2} \) which after exponentiating is equivalent to

\[
\frac{x_1 + x_2}{y_1 + y_2} \leq \frac{y_1 x_2}{x_1 y_2} \iff (x_1 + x_2)x_1 x_2 \leq y_1 y_2 (y_1 + y_2)
\]

\[
\iff 0 \leq y_1^2 x_2 - x_1^2 y_2 + y_2 y_1 - x_2^2 x_1
\]

the latter inequality follows from \( y_1 \geq x_1, y_2 \geq x_2 \).

\( \square \)

Now in order to prove (51) it is enough to show that \( |\phi_{\sigma}^\pm(X) - \phi_{\sigma'}^\pm(X)| \leq d_1(\sigma_1, \sigma'_1) + d_2(\sigma_2, \sigma'_2) \) which in turn via (48) is the same as

\[
\left| \max\{\phi_1^+, \phi_{\sigma_2^+}(X_2)\} - \max\{\phi_{\sigma_1^+}(X_1), \phi_{\sigma_2^+}(X_2)\} \right|
\]

\[
\leq d_1(\sigma_1, \sigma'_1) + d_2(\sigma_2, \sigma'_2)
\]

(54)

\[
\left| \min\{\phi_{\sigma_1^-}(X_1), \phi_{\sigma_2^-}(X_2)\} - \min\{\phi_{\sigma_1^-}(X_1), \phi_{\sigma_2^-}(X_2)\} \right|
\]

\[
\leq d_1(\sigma_1, \sigma'_1) + d_2(\sigma_2, \sigma'_2),
\]

(55)

which in turn follow from the following:

**Lemma 5.4** For any real numbers \( x_1, x_2, y_1, y_2 \) we have:

\[
|\max\{x_1, x_2\} - \max\{y_1, y_2\}| \leq |x_1 - y_1| + |x_2 - y_2|
\]

\[
|\min\{x_1, x_2\} - \min\{y_1, y_2\}| \leq |x_1 - y_1| + |x_2 - y_2|
\]

**Proof** If \( \max\{x_1, x_2\} = x_i \) and \( \max\{y_1, y_2\} = y_i \) for the same \( i \), then the inequalities follow immediately. So let \( \max\{x_1, x_2\} = x_i \ max\{y_1, y_2\} = y_j, i \neq j \), e.g. let \( i = 1, j = 2 \). Then \( x_1 \geq x_2, y_1 \leq y_2 \), and the lemma follows from:

\[
|\max\{x_1, x_2\} - \max\{y_1, y_2\}| = |x_1 - y_2|
\]

\[
= \begin{cases} 
  x_1 - y_2 = x_1 - y_1 + y_1 - y_2 \leq x_1 - y_1 & \text{if } x_1 \geq y_2 \\
  y_2 - x_1 = y_2 - x_2 + x_2 - x_1 \leq y_2 - x_2 & \text{if } x_1 \leq y_2
\end{cases}
\]

(56)

\[
|\min\{x_1, x_2\} - \min\{y_1, y_2\}| = |x_2 - y_1|
\]

\[
= \begin{cases} 
  x_2 - y_1 = x_2 - x_1 + x_1 - y_1 \leq x_1 - y_1 & \text{if } x_2 \geq y_1 \\
  y_1 - x_2 = y_1 - y_2 + y_2 - x_2 \leq y_2 - x_2 & \text{if } x_2 \leq y_1
\end{cases}
\]

(57)

\( \square \)
Thus, we have (50), (51) and they imply that (45) is homeomorphism for \( n = 2 \).

Let \( \text{Stab}(T) \xrightarrow{\text{proj}} \text{Hom}(K_0(T), \mathbb{C}), \text{Stab}(T_i) \xrightarrow{\text{proj}} \text{Hom}(K_0(T_i), \mathbb{C}) \), \( i = 1, 2 \) be the projections \( \text{proj}(Z, \mathcal{P}) = Z \). Then the following diagram (the first row is the map (45) and the second row is the assignment \( Z \mapsto (Z \circ \text{pr}_1, Z \circ \text{pr}_2) \)) is commutative:

\[
\begin{array}{cc}
\text{Stab}(T) & \xrightarrow{\varphi} & \text{Stab}(T_1) \times \text{Stab}(T_2) \\
\downarrow \text{proj} & & \downarrow \text{proj}_1 \times \text{proj}_2 \\
\text{Hom}(K_0(T), \mathbb{C}) & \xrightarrow{\varphi'} & \text{Hom}(K_0(T_1), \mathbb{C}) \times \text{Hom}(K_0(T_2), \mathbb{C}).
\end{array}
\]

If we take any connected component \( \Sigma \subset \text{Stab}(T) \), then (since \( \varphi \) is homeomorphism) \( \varphi(\Sigma) = \Sigma_1 \times \Sigma_2 \) is a connected component of \( \text{Stab}(T_1) \times \text{Stab}(T_2) \), resp. \( \Sigma_i \) are connected components of \( \text{Stab}(T_i) \), and furthermore \( m = \dim_{\mathbb{C}}(\Sigma) = \dim_{\mathbb{C}}(\Sigma_1 \times \Sigma_2) \). From the Bridgeland’s main theorem we know that \( \text{proj} \) restricts to local biholomorphisms between \( \Sigma \) and an \( m \)-dimensional vector subspace \( V \subset \text{Hom}(K_0(T), \mathbb{C}) \) and \( \text{proj}_1 \times \text{proj}_2 \) restricts to local biholomorphisms between \( \Sigma_1 \times \Sigma_2 \) and an \( m \)-dimensional vector subspace \( V_1 \times V_2 \subset \text{Hom}(K_0(T_1), \mathbb{C}) \times \text{Hom}(K_0(T_2), \mathbb{C}) \). It follows (using that \( \varphi' \) is a linear isomorphism and that each open subset in a vector subset contains a basis of the space) that \( \varphi'(V) = V_1 \times V_2 \). Thus, the diagram above restricts to a diagram with vertical arrows which are local biholomorphisms, the bottom arrow is biholomorphism, and the top arrow is a homeomorphism, it follows with standard arguments that the the top arrow must be biholomorphic. It follows that \( \varphi \) is biholomorphism and we proved the proposition. \( \square \)

From this proposition and Definition 4.3 it follows:

**Corollary 5.5** Let \( T = T_1 \oplus T_2 \oplus \cdots \oplus T_n \) be an orthogonal decomposition (Definition 5.1) and let \( \text{rank}(K_0(T_i)) < +\infty \) for \( i = 1, \ldots, n \). Let \( \text{Stab}(T) \rightarrow \text{Stab}(T_1) \times \cdots \times \text{Stab}(T_n) \), \( \sigma \mapsto (\sigma_1, \sigma_2, \ldots, \sigma_n) \) be the biholomorphism from Proposition 5.2a.

For any \( 0 < \varepsilon < 1 \) the following are equivalent: (a) \( \sigma \in \text{Stab}_\varepsilon(T) \); (b) \( \{\sigma_i \in \text{Stab}_\varepsilon(T_i)\}_{i=1}^n \) and there exists a closed \( \varepsilon \)-arc \( \gamma \) such that \( P_{\sigma_i}^T \cap \gamma = \emptyset \) for each \( 1 \leq i \leq n \).

In particular \( T \) has a phase gap iff \( T_i \) has a phase gap for each \( 1 \leq i \leq n \).

Since the closure of \( A \cup B \) equals the union of closures of \( A \) and \( B \) and \( \text{vol}(A) \leq \text{vol}(A \cup B) \leq \text{vol}(A) + \text{vol}(B) \), from Corollary 5.5 it follows:

**Corollary 5.6** Let \( T = T_1 \oplus T_2 \oplus \cdots \oplus T_n \) be an orthogonal decomposition with finite rank Grothendieck groups of the factors, and let \( 0 < \varepsilon < 1 \).

If \( T \) has a phase gap and \( \|T_j\|_{\varepsilon} = 0 \) for some \( j \), then \( \|T\|_{\varepsilon} = \|T_1, T_2, T_{j-1}, T_{j+1}, \ldots, T_n\|_{\varepsilon} \).

**6 The inequality** \( \|\langle T_1, T_2 \rangle\|_{\varepsilon} \geq \max\{\|T_1\|_{\varepsilon}, \|T_2\|_{\varepsilon}\} \)

Here we show conditions which ensure \( \|\langle T_1, T_2 \rangle\|_{\varepsilon} \geq \max\{\|T_1\|_{\varepsilon}, \|T_2\|_{\varepsilon}\} \) for any \( \varepsilon \in (0, 1) \), where \( \langle T_1, T_2 \rangle \) is a semi-orthogonal decomposition (see Definition 5.1) of some \( T \).
Theorem 6.1 Let $T$ be proper and let $K_0(T)$ has finite rank. Assume $0 < \varepsilon < 1$. Let $T = \langle T_1, T_2 \rangle$ be a semi-orthogonal decomposition. If $T_1, T_2$ are categories with phase gaps, then $T$ is a category with phase gap and for any $0 < \varepsilon < 1$ holds:

$$\|\langle T_1, T_2 \rangle\|_\varepsilon \geq \max \left\{ \|T_1\|_\varepsilon, \|T_2\|_\varepsilon \right\}.$$  \hspace{1cm} (58)

Proof Take any $0 < \mu$. Let $\sigma_i = (Z_i, P_i) \in \text{Stab}_\varepsilon(T_i)$ be full stability conditions, s. t.

$$\frac{\text{vol} \left( \frac{P_{\sigma_i}^{T_i}}{2} \right)}{\|T_i\|_\varepsilon} > \|T_i\|_\varepsilon - \mu \quad \text{for} \quad i = 1, 2.$$  \hspace{1cm} (59)

Due to (36) we can assume that $\exp(i\pi [0, \varepsilon]) \subset \mathbb{S}^1 \setminus P_{\sigma_i}^{T_i}$. By the same arguments as in the last paragraph of the proof of Lemma 4.7 it follows that $P_{\sigma_i}(0, 1)$ are finite length abelian categories, therefore the simple objects in them are a basis of $K_0(T_i)$ for $i = 1, 2$, and these abelian categories are the extension closures of their simple objects. In particular the sets of simple objects are finite and it follows that for some $j \in \mathbb{Z}$ holds

$$\text{Hom}^{\leq 1}(P_{\sigma_1}(0, 1], P_{\sigma_2}(0, 1)[j]) = \text{Hom}^{\leq 1}(P_{\sigma_1}(0, 1], P_{\sigma_2}(j, j + 1]) = 0.$$  \hspace{1cm} (61)

Recalling (29) we deduce that $\text{Hom}^{\leq 1}(P_{\sigma_1}(0, 1], P_{(-i \pi) \ast \sigma_2}(0, 0+1]) = 0$. By replacing $\sigma_2$ with $(-i \pi) \ast \sigma_2$ we obtain stability conditions $\sigma_i \in \text{Stab}_\varepsilon(T_i)$ for $i = 1, 2$ satisfying the following conditions:

$$\text{vol} \left( \frac{P_{\sigma_i}^{T_i}}{2} \right) > \|T_i\|_\varepsilon - \mu \quad \text{for} \quad i = 1, 2.$$  \hspace{1cm} (62)

$$\text{Hom}^{\leq 1}(P_{\sigma_1}(0, 1], P_{\sigma_2}(0, 1]) = 0.$$  \hspace{1cm} (63)

$P_{\sigma_2}(0, 1]$ and $P_{\sigma_2}(0, 1]$ are of finite length and with finitely many simples, $P_{\sigma_i}(t) = \{0\}$ for $t \in [j, j + \varepsilon]$ for $i = 1, 2, j \in \mathbb{Z}$.  \hspace{1cm} (64)

In the listed properties of $\sigma_i \in \text{Stab}(T_i)$ with the given semi-orthogonal decomposition $T = \langle T_1, T_2 \rangle$ are contained the conditions of [16, Proposition 3.5 (b)]. This proposition ensures a glued (see [16, Definition ]) locally finite stability condition $\sigma = (Z, P) \in \text{Stab}(T)$. The glued stability condition satisfies the following (we use [16, Proposition 2.2.2 (3)]) and write $P_i$ instead of $P_{\sigma_i}$

$$P(0, 1] \text{ is extension closure of } P_1(0, 1], P_2(0, 1]$$  \hspace{1cm} (65)

$\forall i \in \{1, 2\} \forall t \in \mathbb{R} \quad P_i(t) \subset P(t)$

$$Z(X) = Z_1(X) \text{ for } X \in T_1; \quad Z(X) = Z_2(X) \text{ for } X \in T_2.$$  \hspace{1cm} (66)
Indeed, let $P \in \mathbb{P}(0,1)$ and $\mathbb{P}(1,0)$ respectively. Then $\{s(1,1), s(1,2), \ldots, s(2, n)\}$ be the simple objects of $\mathbb{P}(0,1)$ and $\mathbb{P}(1,0)$, respectively.
Corollary 6.4 Let $X$ be a smooth algebraic variety and let $Y$ be a smooth sub-variety so that $K_0(D^b(X))$, $K_0(D^b(Y))$ have finite rank and $D^b(X)$, $D^b(Y)$ have phase gaps. Denote by $\tilde{X}$ the smooth algebraic variety obtained by blowing up $X$ along the center $Y$.

Then $D^b(\tilde{X})$ has phase gap and $\|D^b(\tilde{X})\|_\varepsilon \geq \max \{\|D^b(X)\|_\varepsilon, \|D^b(Y)\|_\varepsilon\}$ for any $\varepsilon \in (0, 1)$.

Proof [7, Theorem 4.2] ensures that there is a semi-orthogonal decomposition $D^b(\tilde{X}) = \langle T_1, T_2, \ldots, T_k, D^b(X) \rangle$, where $T_i$ is equivalent to $D^b(Y)$ for $i = 1, 2, \ldots, k$. Now Theorem 6.1 ensures that the inequality holds. \hfill \Box

7 Norm of $D^b(K(l))$

7.1 The Helix in $D^b(K(l))$ for $l \geq 2$

From now on we assume that $l \geq 2$ and denote $T_l = D^b(K(l))$. We write $\dim(X) = (n, m)$, $\dim_0(X) = n$, $\dim_1(X) = m$ for a representation:

$$X = k^n \bigoplus k^m \in \text{Rep}_{\mathbb{K}}(K(l))$$

Recall that $\text{Rep}_{\mathbb{K}}(K(l))$ is hereditary category in which for any two $X, Y \in \text{Rep}_{\mathbb{K}}(Q)$ with dimension vectors $\dim(X) = (n_x, m_x)$, $\dim(Y) = (n_y, m_y)$ holds the equality (the Euler Formula):

$$\hom(X, Y) - \hom^1(X, Y) = n_x n_y + m_x m_y - ln_x my$$

(70)

Let $s_0, s_1 \in T_l$ be so that $s_0[1], s_1$ are the simple objects in $\text{Rep}_{\mathbb{K}}(Q)$ with $\dim(s_0[1]) = (1, 0)$ and $\dim(s_1) = (0, 1)$. Using (70) one easily computes $\hom(s_0, s_1) = l$, $\hom^p(s_0, s_1) = 0$ for $p \neq 0$ and $\hom^*(s_1, s_0) = 0$. With the terminology from Sect. 2 we say that $(s_0, s_1)$ is a full strong exceptional pair in $T_l = D^b(K(l))$.

Remark 7.1 Recall that (see e.g. [9, p. 222]) for any exceptional pair $(A, B)$ in any proper triangulated category $T$ one defines objects $L_A(B)$ (left mutation) and $R_B(A)$ (right mutation) by the triangles

$$L_A(B) \to \Hom^*(A, B) \otimes A \xrightarrow{ev^*_A,B} B \xleftarrow{coev^*_A,B} \Hom^*(A, B) \otimes B \to R_B(A)$$

(71)

and $(L_A(B), A), (B, R_B(A))$ are exceptional pairs as well, they are full if $(A, B)$ is full.

It follows, that for any exceptional collection $E = (E_0, E_1, \ldots, E_n)$ in $T$ and for any $0 \leq i < n$ the sequences $R_i(E) = (E_0, E_1, \ldots, E_{i+1}, R_{E_{i+1}}(E_i), \ldots, E_n)$, $L_i(E) = (E_0, E_1, \ldots, L_{E_i}(E_{i+1}), E_i, \ldots, E_n)$ are exceptional and $\langle R_i(E) \rangle = \langle L_i(E) \rangle$.
\[ \langle L_i(\mathcal{E}) \rangle = \langle \mathcal{E} \rangle. \] The sequences \( L_i(\mathcal{E}) \) and \( R_i(\mathcal{E}) \) are called left and right mutations of \( \mathcal{E} \).

From the exceptional pair \((s_0, s_1)\) we get objects \( L_{s_0}(s_1), R_{s_1}(s_0) \) via left and right mutation, denoted by \( s_{-1}, s_2 \), respectively, and each two adjacent elements in the sequence \( s_{-1}, s_0, s_1, s_2 \) form a full exceptional pair. Applying iteratively left/right mutations on the left/right standing exceptional pair generates a sequence (infinite in both directions) of exceptional objects \( \{s_i\}_{i \in \mathbb{Z}} \). This is the helix induced by the exceptional pair \((s_0, s_1)\), as defined in [9, p. 222]. In [19, Section 5 - see (25), (27) and Lemma 5.2] with the help of results for geometric helices in [9] and is proved that:

**complete lists of exceptional pairs and objects (up to shifts) are**

\[
\{(s_i, s_{i+1})\}_{i \in \mathbb{Z}} \text{ and } \{s_i\}_{i \in \mathbb{Z}}.
\]  
(72)

**no two elements in \( \{s_i\}_{i \in \mathbb{Z}} \) are isomorphic and \( s_{\leq 0}[1], s_{\geq 1} \in \text{Rep}_{\mathbb{Z}}(K(I)) \)**

\[
\text{for any } i \in \mathbb{Z} \text{ there exists a distinguished triangle}
\]

\[
s_{i-1} \rightarrow s_i \rightarrow s_{i+1} \rightarrow s_{i-1}[1]
\]  
(74)

\[
i \leq j \implies \left\{ \begin{array}{l}
\text{hom}(s_i, s_j) \neq 0 \\
\text{hom}^p(s_i, s_j) = 0 \text{ for } p \neq 0
\end{array} \right.
\]  
(75)

\[
i > j + 1 \implies \left\{ \begin{array}{l}
\text{hom}^1(s_i, s_j) \neq 0 \\
\text{hom}^p(s_i, s_j) = 0 \text{ for } p \neq 1
\end{array} \right.
\]  
(76)

### 7.2 The set of phases

We prove the following Proposition

**Proposition 7.2** We have a disjoint union \( \text{Stab}(T_l) = \mathcal{Z} \sqcup (\sqcup_{i \in \mathbb{Z}} \mathcal{Z}_i) \) and:

\[
\sigma \in \mathcal{Z} \iff \forall i \in \mathbb{Z}, s_i \in \sigma^{ss} \text{ and } \phi(\sigma_i) < \phi(\sigma_{i+1}) < \phi(\sigma_i) + 1
\]  
(77)

\[
\sigma \in \mathcal{Z}_i \iff s_i, s_{i+1} \in \sigma^{ss} \text{ and } \phi(s_i) + 1 \leq \phi(s_{i+1}).
\]  
(78)

The subset \( \mathcal{Z} \) is open and it is biholomorphic to the specified subset of \( \mathbb{C}^2 \) via the following map:

\[
\mathcal{Z} \rightarrow \{(z_1, z_2) \in \mathbb{C}^2; \Im(z_1) < \Im(z_2) < \Im(z_1) + 1\}
\]

\[
\mathcal{Z} \ni (\mathcal{Z}, \mathcal{P}) \mapsto (\log |Z(s_i)| + i\pi \phi_\sigma(s_i), \log |Z(s_{i+1})| + i\pi \phi_\sigma(s_{i+1})).
\]  
(79)

Furthermore, if \( \sigma \in \mathcal{Z}_i \) and \( \phi(s_{i+1}) > \phi(s_i) + 1 \), then \( s_j \notin \sigma^{ss} \) for \( j \neq i \), \( j \neq i + 1 \). If \( \sigma \in \mathcal{Z}_i \) and \( \phi(s_{i+1}) = \phi(s_i) + 1 \), then \( s_j \in \sigma^{ss} \) for each \( j \in \mathbb{Z} \).

**Proof** The existence of a disjoint union \( \text{Stab}(T_l) = \mathcal{Z} \sqcup \sqcup_{i \in \mathbb{Z}} \mathcal{Z}_i \), with the properties (77), (78) and the biholomorphism (79) follow from [23, Proposition 6.1, formula (35), Lemma 6.2].

Assume now that \( \sigma \in \mathcal{Z}_i \) and \( \phi(s_{i+1}) > \phi(s_i) + 1 \) for some \( i \phi(s_{i+1}) > \phi(s_i) + 1 \). If \( s_j \in \sigma^{ss} \) for some \( j > i + 1 \), then due to (75) \( \phi(s_j) \geq \phi(s_{i+1}) \), and hence
Therefore we can write:

\[ \phi(s_j) > \phi(s_i) + 1, \text{ hom}^1(s_j, s_i) = 0, \] which contradicts (76). The arguments for the case \( j < i \) are similar.

Finally, assume that \( \sigma \in \mathbb{Z} \) and \( t = \phi(s_{i+1}) = \phi(s_i) + 1 \). Recall that \( s_0[1] \) and \( s_1 \) are the simple objects in \( \text{Rep}_K(K(l)) \) (see after (70)). It follows that for each \( j \) we have that \( s_j[k] \) is in the extension closure of \( s_0[1] \) and \( s_1 \) for some \( k \). Using [23, Corollary 5.3] one deduces easily that for each \( j \) we have that \( s_j[k] \) is in the extension closure of \( s_i[1] \) and \( s_{i+1} \) for some \( k \), and since \( s_i[1], s_{i+1} \in \mathcal{P}(t) \) it follows that \( s_j[k] \in \mathcal{P}(t) \), therefore \( s_j \in \sigma^{ss} \). \( \square \)

We start by some comments on the root system of \( K(l) \). The root system of \( K(l) \) is

\[ \Delta_{l+} = \Delta_+(K(l)) = \Delta_{l+}^{re} \cup \Delta_{l+}^{im}, \] where \( \Delta_{l+}^{re} = \{(n, m) \in \mathbb{N}^2 : n^2 + m^2 - lmn = 1\} \) and \( \Delta_{l+}^{im} = \{(n, m) \in \mathbb{N}^2 : n^2 + m^2 - lmn \leq 0\} \setminus \{(0, 0)\}. \) It is well known that the real roots \( \Delta_{l+}^{re} \) are exactly the dimension vectors of the exceptional representations in \( \text{Rep}_K(K(l)) \) and for the imaginary roots \( \Delta_{l+}^{im} \) we have formula (74) in [18]. From (72) and Lemma 7.3 we have the complete list \( \{s_{\leq 0}[1], s_{\geq 1}\} \) of exceptional representations in \( \text{Rep}_K(K(l)) \). Let us denote the corresponding dimension vectors as follows:

\[ (n_i, m_i) = \begin{cases} \dim(s_i) & i \geq 1 \\ \dim(s_i[1]) & i \leq 0 \end{cases} \] (80)

Therefore we can write:

\[ \Delta_{l+}^{re} = \{(n_i, m_i) : i \in \mathbb{Z}\} \]
\[ \Delta_{l+} = \{(n_i, m_i) : i \in \mathbb{Z}\} \cup \left\{ a_i^{-1} \leq \frac{n}{m} \leq a_i : n \in \mathbb{N}_{\geq 1}, m \in \mathbb{N}_{\geq 1}\right\}. \] (81)
\[ a_i = \frac{l + \sqrt{l^2 - 4}}{2} \Rightarrow a_i^{-1} = \frac{l - \sqrt{l^2 - 4}}{2}; \quad a_i^{-1} + a_i = \frac{a_i^2 + 1}{a_i} = l. \] (82)

We will need later the following facts for the real roots \( \{(n_i, m_i) : i \in \mathbb{Z}\} \):

**Lemma 7.3** (a) \( (n_{-1}, m_{-1}) = (l, 1), (n_0, m_0) = (1, 0), (n_1, m_1) = (0, 1), (n_2, m_2) = (1, l) \)
(b) \( (m_{-i}, n_{-i}) = (n_{i+1}, m_{i+1}) \) for \( i \geq 0 \).
(c) \( n_{i+} > m_{i+} \) and \( n_{i+1} < m_{i+1} \) for \( i \geq 0 \); \( n_{i+1} > 0 \) and \( m_{i-} > 0 \) for \( i \geq 1 \).
(d) \( \frac{n_i}{m_i} = \frac{l}{2} - \sqrt{\frac{l^2}{4} + \frac{1}{m_i^2}}, \quad \frac{n_{i-1}}{m_{i-1}} = \frac{l}{2} + \sqrt{\frac{l^2}{4} + \frac{1}{m_{i-1}^2}} \) for \( i \geq 1 \).
(e) \( \frac{n_{-i}}{m_{-i}} > \frac{n_{-i+1}}{m_{-i+1}} > \cdots > \frac{n_{-1}}{m_{-1}} \xrightarrow{i \to \infty} a_i \) and \( 0 = \frac{n_1}{m_1} < \frac{n_2}{m_2} < \cdots < \frac{n_i}{m_i} \xrightarrow{i \to \infty} a_i^{-1} \).

**Proof** (a) \( (n_0, m_0) = (1, 0), (n_1, m_1) = (0, 1) \) follow from the definition. The triangles (74) for \( i = 1, \) and \( i = 0 \) amount to short exact sequences: \( s_1^{l_1} \to s_2 \to s_0[1] \) and \( s_1 \to s_{-1}[1] \to s_0[1] \) in \( \text{Rep}_K(K(l)) \), and it follows that \( \dim(s_2) = (1, l), \dim(s_{-1}[1]) = (l, 1) \)
(b) The equality for \( 0 \leq i \leq 1 \) follows from (a). We make the induction assumption that for some \( p \geq 1 \) the equality holds for any \( 0 \leq i \leq p \), we will make the induction step, namely that the equality for \( i = p + 1 \) follows from this induction assumption. Indeed, for \( i \geq 1 \)
from (74) we obtain the following short exact sequences in $\text{Rep}_\kappa(K(l))$: $s_{-i-1}[1] \to s_{-i}^l[1] \to s_{-i+1}[1]$, $s_i \to s_{i+1}^l \to s_{i+2}$ therefore for $i \geq 1$ we obtain:

\begin{align}
  n_{-i-1} &= \ln_{-i} - n_{-i+1} & m_{-i-1} &= \ln_{-i} - m_{-i+1} \\
  n_{i+2} &= \ln_{i+1} - n_i & m_{i+2} &= \ln_{i+1} - m_i
\end{align}

(83)

(84)

having these recursive formulas one easily carries out the inductive step.

(c) Due to (b) it is enough to show that $n_{i+1} < m_{i+1}$. For $i = 0$ this is shown in (a). For $i \geq 1$ we have $\text{hom}(s_{i+1}, s_{-i}[1]) > 0$, $\text{hom}^1(s_{i+1}, s_{-i}[1]) = 0$ (recall Lemma 7.3), hence the Euler formula amounts to:

\begin{align}
  \{\dim(s_{i+1}), \dim(s_{-i}[1])\} &= \text{hom}(s_{i+1}, s_{-i}[1]) - \text{hom}^1(s_{i+1}, s_{-i}[1]) > 0 \\
  \Rightarrow (n_{i+1}, m_{i+1}), (n_{-i}, m_{-i}) &= n_{i+1}n_{-i} + m_{i+1}m_{-i} - \ln_{i+1}m_{-i} > 0.
\end{align}

Putting the equality from (b) in the last inequality we get $n_{i+1}m_{i+1} + m_{i+1}n_{i+1} - \ln_{i+1}n_{i+1} > 0$. Therefore $n_{i+1}(2m_{i+1} - \ln_{i+1}) > 0$, hence $n_{i+1} > 0$, $m_{i+1} > \frac{1}{2}n_{i+1} \geq n_{i+1}$ and (c) is proved.

(d) Take any $i \in \mathbb{Z}$, $i \neq 0$. From (c) we know that $m_i \neq 0$. From (81) we know that

\[ n_i^2 + m_i^2 - \ln_i m_i = 1, \]

hence via the quadratic equation $\left(\frac{m_i}{m_i}\right)^2 - l\frac{m_i}{m_i} + 1 - \frac{1}{m_i} = 0$

we get $\frac{n_i}{m_i} = \frac{1}{2} \left( l \pm \sqrt{l^2 - 4 + \frac{4}{m_i^2}} \right)$. One checks that $\frac{1}{2} \left( l + \sqrt{l^2 - 4 + \frac{4}{m_i^2}} \right) > 1$, $\frac{1}{2} \left( l - \sqrt{l^2 - 4 + \frac{4}{m_i^2}} \right) < 1$ and then from (c) we deduce (d).

(e) Using (83), (84), and induction one shows that $m_i < m_{i+1}$, $m_{-i-1} > m_{-i}$ for $i \geq 0$ and then (e) follows from (d).

\[ \Box \]

We write for short $P^l_\sigma$ instead of $P^T_\sigma$, and now we determine $P^l_\sigma$.

**Proposition 7.4.** Let $\text{Stab}(T_l) = \mathbb{Z} \sqcup \bigcup_{i \in \mathbb{Z}} \mathbb{Z}_i$ be the decomposition from Proposition 7.2. Let $\sigma \in \text{Stab}(D^b(K(l)))$.

(a) If $\sigma \notin \mathbb{Z}$, then the set of phases $P^l_\sigma$ is finite (has up to 4 elements).

(b) If $\sigma \in \mathbb{Z}$, then for any $j \in \mathbb{Z}$ we have the following formulas:

\[ 0 < \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) < 1 \]

\[ \exp(i\pi(1 - \phi_\sigma(s_j))) \cdot P^l_\sigma = \{0\} \cup \{\pm \exp(i\pi(n_i/m_i)) : i \neq 0\} \cup \pm \exp(i\pi(\mathbb{Q} \cap [a^{-1}, a])) \]

(85)

(86)

where $x$, $y$, and the function (strictly increasing smooth) $f : [0, \infty) \to [\pi(\phi_\sigma(s_{j+1}) - \phi_\sigma(s_j)), \pi]$ are:
\[ f(t) = \arccos \left( \frac{xy - t}{\sqrt{t^2 + x^2 - 2txy}} \right) \quad x = \frac{|Z(s_{j+1})|}{|Z(s_j)|} \]

\[ y = \cos \left( \pi (\phi_\sigma(s_{j+1}) - \phi_\sigma(s_j)) \right). \tag{87} \]

(c) For \( \sigma \in \mathbb{Z} \) holds the equality \( \{ \pm \exp(i \pi \phi_\sigma(s_j)) \}_{i \in \mathbb{Z}} = P^I_{\sigma} \setminus L(P^I_{\sigma}) \) (recall that by \( L(P^I_{\sigma}) \) we denote the set of limit points in the circle of \( P^I_{\sigma} \)).

(d) For any \( \sigma \in \mathbb{Z} \) and any \( j \in \mathbb{Z} \) hold:

\[
\lim_{k \to +\infty} \pi \phi_\sigma(s_k[-1]) = u_\sigma \leq v_\sigma = \lim_{k \to -\infty} \pi \phi_\sigma(s_k) \tag{88}\]

\[
\pi \phi_\sigma(s_j - 1) < \pi \phi_\sigma(s_{j+1}[-1]) < \pi \phi_\sigma(s_{j+2}[-1]) < \cdots < u_\sigma \leq v_\sigma < \cdots \leq \pi \phi_\sigma(s_{j-2}) < \pi \phi_\sigma(s_{j-1}) < \pi \phi_\sigma(s_j) \tag{89}\]

\[
\frac{v_\sigma - u_\sigma}{u_\sigma - \pi \phi_\sigma(s_{j+1}[-1])} = \frac{f(a_i) - f(a_i^{-1})}{f(a_i^{-1}) - \arccos(y)} \quad \frac{v_\sigma - u_\sigma}{\pi \phi_\sigma(s_j) - v_\sigma} \tag{90}\]

\[
\frac{f(a_i) - f(a_i^{-1})}{\pi - f(a_i)}, \tag{91}\]

where \( f, x, y \) are as in (87) and \( u_\sigma = f(a_i^{-1}) + \pi (1 - \phi_\sigma(s_j)), \quad v_\sigma = f(a_i) + \pi (1 - \phi_\sigma(s_j)) \).

(e) Let \( \sigma \in \mathbb{Z} \) and \( 0 < \varepsilon < 1 \). Then \( \mathbb{S}^1 \setminus P^I_{\sigma} \) contains a closed \( \varepsilon \)-arc iff there exists \( i \in \mathbb{Z} \) such that \( \phi_\sigma(s_{i+1}) - \phi_\sigma(s_i) > \varepsilon \).

Before giving the proof of this proposition we make some preparatory steps.

For a pair of complex numbers \( v = (z_1, z_2) \) we discussed in \([18]\) (see \([18, \text{Lemma 3.18}]\) and the first row of the proof) the following subset of the circle

\[
R_{v, \Delta_{l+}} = \left\{ \pm \frac{n z_1 + m z_2}{|n z_1 + m z_2|} | (n, m) \in \Delta_{l+} \right\} \subset \mathbb{S}^1. \tag{92}\]

From \([18, \text{Remark 3.16}]\) and (81) we deduce that:

**Lemma 7.5** For any pair of complex numbers \( v = (z_1, z_2) \) of the form \( z_i = r_i \exp(i \phi_i) \), \( r_i > 0, \ i = 1, 2, 0 < \phi_2 < \phi_1 \leq \pi \) holds:

\[
R_{v, \Delta_{l+}} = \{ \pm \exp(i \phi_1) \} \cup \{ \pm \exp(i f(n_i/m_i)) : i \neq 0 \}
\]

\[
\cup \{ \pm \exp(i f(n/m)) : n/m \in [a_i^{-1}, a_i] \} \tag{93}\]

where \( f : [0, \infty) \to [\phi_2, \phi_1) \subset (0, \pi) \) is the strictly increasing smooth function:

\[
f(t) = \arccos \left( \frac{tr_1 \cos(\phi_1) + r_2 \cos(\phi_2)}{\sqrt{t^2 r_1^2 + r_2^2 + 2tr_1r_2 \cos(\phi_1 - \phi_2)}} \right). \]
\[ f(0) = \phi_2, \quad \lim_{t \to \infty} f(t) = \phi_1. \] (94)

**Proof of Proposition 7.4** Let \( \sigma = (Z, \mathcal{P}) \in \text{Stab}(D^b(K(l))) \). From Proposition 7.2 we have either \( \sigma \in \mathcal{Z}_j \) for some \( j \in \mathbb{Z} \) or \( \sigma \in \mathcal{Z} \).

(a) Assume first that \( \sigma \in \mathcal{Z}_j \) for some \( j \in \mathbb{Z} \). Then by (78) we see that

\[ s_j, s_{j+1} \in \sigma^{ss} \quad \phi(s_j) + 1 \leq \phi(s_{j+1}). \] (95)

We will show that in this case \( P^l_\sigma = \{ \pm \exp(i\pi \phi_\sigma(s_j)), \pm \exp(i\pi \phi_\sigma(s_{j+1})) \} \). Indeed, (95) implies that there exists \( k \geq 1 \) such that \( \phi(s_j) \leq \phi(s_{j+1}[-k]) < \phi(s_j) + 1 \). From Lemma 7.3 it follows that \( (s_j, s_{j+1}[-k]) \) is a \( \sigma \)-exceptional pair (as defined in [22, Definition 3.17]). From [22, Corollary 3.18] (and its proof) it follows that the extension closure of \( (s_j, s_{j+1}[-k]) \) equals \( \mathcal{P}(t, t+1) \) for some \( t \in \mathbb{R} \). Since \( (s_j, s_{j+1}[-k]) \) is an exceptional pair, each element \( Y \) in the extension closure of \( (s_j, s_{j+1}[-k]) \) can be put in a triangle of the form \( s_{j+1}[-k]^a \xrightarrow{\alpha} Y \xrightarrow{\beta} s_j \xrightarrow{b} s_{j+1}[-k+1]^a \) for some \( a, b \in \mathbb{N} \). Take any \( X \in \sigma^{ss} \), then for some \( i \in \mathbb{Z} \) we have \( \phi_\sigma(X[i]) \in (t, t+1) \) and therefore we have a triangle:

\[ s_{j+1}[-k]^a \xrightarrow{\alpha} X[i] \xrightarrow{\beta} s_j \xrightarrow{b} s_{j+1}[-k+1]^a. \] (96)

\[ \square \]

If \( a = 0 \) or \( b = 0 \), then \( X[i] \cong s_j^b \) or \( X[i] \cong s_{j+1}[-k]^a \) and hence \( \phi_\sigma(X[i]) = \phi(s_j) \) or \( \phi_\sigma(X[i]) = \phi(s_{j+1}[-k]) \) and the \( \exp(i\pi \phi_\sigma(X)) \in \{ \pm \exp(i\pi \phi_\sigma(s_j)), \pm \exp(i\pi \phi_\sigma(s_{j+1})) \} \).

Next assume that \( a \neq 0 \) and \( b \neq 0 \). If \( \phi(s_j) = \phi(s_{j+1}[-k]) \), then we get \( \exp(i\pi \phi_\sigma(X)) = \exp(i\pi \phi_\sigma(s_j)) \) using (96). Thus, we reduce to \( \phi(s_j) < \phi(s_{j+1}[-k]) \), which in turn by (96), \( X[i] \in \sigma^{ss} \), and (18) implies that \( \alpha = 0 \) or \( \beta = 0 \). If \( \alpha = 0 \), then \( s_j^b \cong X[i] \oplus s_{j+1}[-k+1]^b \) and by [22, Lemma 3.7] it follows that \( \phi(s_j) = \phi(X[i]) = \phi(s_{j+1}[-k+1]) \); if \( \beta = 0 \), then \( s_{j+1}[-k]^a \cong X[i] \oplus s_j[-1]^b \) and by [22, Lemma 3.7] it follows that \( \phi(s_{j+1}[-k]) = \phi(X[i]) = \phi(s_{j}[-1]) \). Thus we see that (95) implies \( P^l_\sigma = \{ \pm \exp(i\pi \phi_\sigma(s_j)), \pm \exp(i\pi \phi_\sigma(s_{j+1})) \} \) and (a) is proved.

(b) If \( \sigma \in \mathcal{Z}_j \), then (77) shows that for any \( j \in \mathbb{Z} \) holds \( s_j, s_{j+1} \in \sigma^{ss} \), \( \phi_\sigma(s_j) < \phi_\sigma(s_{j+1}) < \phi_\sigma(s_j) + 1 \). Choosing one \( j \in \mathbb{Z} \), denoting \( \sigma' = (Z', \mathcal{P}') = (-\log |Z(s_j)| + i\pi (1 - \phi_\sigma(s_j))) \star \sigma \) and using (30), (31), we get:

\[ Z'(s_j) = -1, \quad |Z'(s_{j+1})| = \frac{|Z(s_{j+1})|}{|Z(s_j)|}, \]

\[ \phi_{\sigma'}(s_{j+1}) = \phi_\sigma(s_{j+1}) + 1 - \phi_\sigma(s_j) \] (97)

\[ 1 = \phi_{\sigma'}(s_j) < \phi_{\sigma'}(s_{j+1}) < \phi_{\sigma'}(s_j) + 1 = 2 \]

\[ \Rightarrow 0 < \phi_{\sigma'}(s_{j+1}[-1]) < \phi_{\sigma'}(s_j) = 1. \] (98)
Let $\mathcal{A}$ be the heart of the bounded t-structure of $\mathcal{T}_f$ (Remark 3.16) and the equality $\mathcal{A} = \mathcal{P}'(0, 1)$ holds for any $\sigma' \in A^1$ (see also 97). Now all the conditions of [21, Corollary 3.21] and the exceptional pair $(s_j, s_{j+1}[-1])$ hold and we deduce that

$$\mathcal{P}' = R_{\sigma', \Delta_i}.$$

To determine the set $R_{\sigma', \Delta_i}$ we use Lemma 7.5 and observe that now (see 96) $v = (-1, \frac{\sigma_j}{Z(s_j)}) \exp(\pi \sigma_j) < \pi$, where $\sigma_j = (\mathcal{P}'(0, 1)) \exp(\pi \sigma_j) < \pi$, and therefore the equality (93) yields (96) and the function (94) has the form (95).

(c) Let $\sigma \in Z$. In (b) $j$ was any integer, here we choose $j = 0$. Now formulas (97) and (98) give:

$$Z'(s_0) = -1 \quad Z'(s_1[-1]) = |Z'(s_1)| \exp(i \pi \phi_{\sigma'}(s_1[-1])),\quad 0 < \phi_{\sigma'}(s_1[-1]) < \phi_{\sigma'}(s_0) = 1.$$

Since $s_0[1], s_1$ are the simple representations and since $s_{i+1} \leq s_0[1] \in \text{Rep}_Z(K(l))$ (Lemma 7.3), it follows that (see also 80) for any $i \geq 1 Z'(s_i) = n_i Z'(s_0[1]) + m_i Z'(s_1)$, and for any $i \leq 0 Z'(s_i) = n_i Z'(s_0[1]) + m_i Z'(s_1)$, and now using [18, Remark 3.16] (in particular $f$ is as in 87) we obtain:

$$Z'(s_i) = \begin{cases} \pm n_i Z'(s_0) + m_i Z'(s_1[-1]) & i \geq 1 \\ \mp |n_i Z'(s_0)| + m_i Z'(s_1[-1]) & i = 0 \\ \pm n_i Z'(s_0) + m_i Z'(s_1[-1]) & i \leq 0 \end{cases}$$

(100)

In (b) we showed that $\mathcal{P}_\sigma = \mathcal{P}_\sigma'$ equals the set on the RHS of (86). Due to Lemma 7.3 we get that $L(\mathcal{P}_\sigma') = \pm \exp(i f \left(\left[a_i^{-1}, a_i\right]\right))$, and therefore (100) and (17) imply that $\mathcal{P}_\sigma, \mathcal{P}_\sigma' \cap L(\mathcal{P}_\sigma') = \{\pm \exp(i \pi \phi_{\sigma'}(s_i))\}_{i \in \mathbb{Z}}$. Recalling that $\sigma' = \lambda \circ \sigma$ for certain $\lambda \in G$ with the help of formulas (30) and (35) we deduce the desired equality $\mathcal{P}_\sigma \cap L(\mathcal{P}_\sigma') = \{\pm \exp(i \pi \phi_{\sigma'}(s_i))\}_{i \in \mathbb{Z}}$.

(d) In (b) we showed that $\mathcal{P}_\sigma'$ equals the RHS of (86) and taking into account Lemma 7.3 we deduce that $\mathcal{P}_\sigma \cap L(\mathcal{P}_\sigma') = \pm 1 \cup \{\pm \exp(i f(n_i/m_i)) : i \neq 0\}$, which combined with (c) yields:

$$\pm 1 \cup \{\pm \exp(i f(n_i/m_i)) : i \neq 0\} = \{\pm \exp(i \pi \phi_{\sigma'}(s_i))\}_{i \in \mathbb{Z}}.$$

(101)

Recalling that (85) holds for any $j \in Z$ and also (76), (98) we derive:

$$0 = \phi_{\sigma'}(s_j) - 1 < \phi_{\sigma'}(s_{j+1}[-1]) < \phi_{\sigma'}(s_{j+2}[-1]) < \cdots < \phi_{\sigma'}(s_{j-2})$$
\[ < \phi_{\sigma'}(s_{j-1}) < \phi_{\sigma'}(s_j) = 1 \]  

(102)

We already know that (see (b) of the proposition and (e) in Lemma 7.3)

\[
\begin{align*}
  f(0) &= f(n_1/m_1) = \pi(\phi_{\sigma}(s_{j+1}) - \phi_{\sigma}(s_j)) \\
  &= \pi \phi_{\sigma'}(s_{j+1}[-1]) = \arccos(y).
\end{align*}
\]

(103)

Furthermore from (e) in Lemma 7.3 we deduce:

\[
\begin{align*}
  0 < f\left(\frac{n_1}{m_1}\right) < f\left(\frac{n_2}{m_2}\right) < \cdots < f\left(a_i^{-1}\right) \\
  \leq f(a_i) < \cdots < f\left(\frac{n-2}{m-2}\right) < f\left(\frac{n-1}{m-1}\right) < \pi.
\end{align*}
\]

(104)

By induction the equalities (101), (102), (104) imply:

\[
  k \geq 1 \implies f\left(\frac{n_k}{m_k}\right) = \pi \phi_{\sigma'}(s_{j+k}[-1]) = f\left(\frac{n_k}{m_k}\right) = \pi \phi_{\sigma'}(s_{j-k}).
\]

(105)

Now recalling that (see (31))

\[
\forall i \in \mathbb{Z} \quad \phi_{\sigma'}(s_i) = \phi_{\sigma}(s_i) + 1 - \phi_{\sigma}(s_j)
\]

(106)

we deduce (88), (89), (91) from (105), (103), and (102). The equality (90) in turn follows from (86), (105), (106).

(e) Follows easily from the already proven (d).

### 7.3 Computing \( \|D^b(K(l))\|_\ell \)

If we define the function:

\[
F : (0, +\infty) \times (-1, 1) \times (0, +\infty) \rightarrow (0, \pi)
\]

\[
F(x, y, t) = \arccos\left(\frac{xy - t}{\sqrt{t^2 + x^2 - 2txy}}\right)
\]

(107)

then using Proposition 7.4 (a), Lemma 7.3 (e), and formulas (86), (87) one concludes that:

**Proposition 7.6** Let \( \sigma = (Z, P) \in \text{Stab}(T_l) \).

If \( \sigma \notin Z \), then \( \text{vol} \left( P_{\sigma}^l \right) = 0 \). If \( \sigma \in Z \), then for any \( j \in \mathbb{Z} \) holds:

\[
\frac{1}{2} \text{vol} \left( P_{\sigma}^l \right) = F(x_j(\sigma), y_j(\sigma), a_i) - F(x_j(\sigma), y_j(\sigma), a_i^{-1}),
\]

If we define the function:

\[
F : (0, +\infty) \times (-1, +1) \times (0, +\infty) \rightarrow (0, \pi)
\]

\[
F(x, y, t) = \arccos\left(\frac{xy - t}{\sqrt{t^2 + x^2 - 2txy}}\right)
\]

(107)

then using Proposition 7.4 (a), Lemma 7.3 (e), and formulas (86), (87) one concludes that:

**Proposition 7.6** Let \( \sigma = (Z, P) \in \text{Stab}(T_l) \).

If \( \sigma \notin Z \), then \( \text{vol} \left( P_{\sigma}^l \right) = 0 \). If \( \sigma \in Z \), then for any \( j \in \mathbb{Z} \) holds:

\[
\frac{1}{2} \text{vol} \left( P_{\sigma}^l \right) = F(x_j(\sigma), y_j(\sigma), a_i) - F(x_j(\sigma), y_j(\sigma), a_i^{-1}),
\]
where \( x_j(\sigma) = \frac{|Z(s_{j+1})|}{|Z(s_j)|} \) \( y_j(\sigma) = \cos \left( \pi \left( \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) \right) \right) \).

(108)

One computes

\[
\frac{\partial}{\partial x} F(x, y, t) = -t\sqrt{1 - y^2} \quad \frac{\partial}{\partial t} F(x, y, t) = \frac{x\sqrt{1 - y^2}}{t^2 + x^2 - 2txy}
\]

(109)

and therefore:

\[
\frac{\partial}{\partial x} \left( F(x, y, a_l) - F(x, y, a_{l-1}) \right) = \frac{a_l(a_l^2 - 1)\sqrt{1 - y^2}}{(1 + (a_l x)^2 - 2a_l xy)(a_l^2 + x^2 - 2a_l xy)}(1 - x^2),
\]

(110)

which implies that for any \( x > 0, y \in (-1, +1) \) we have:

\[
F(x, y, a_l) - F(x, y, a_{l-1}) \leq F(1, y, a_l) - F(1, y, a_{l-1})
\]

(111)

On the other hand one computes that for any \( y \in (-1, +1), t \in (0, +\infty) \) holds:

\[
F(1, y, a_l) - F(1, y, a_{l-1}) = \arccos \left( \frac{y - a_l}{\sqrt{a_l^2 + 1 - 2a_l y}} \right) - \arccos \left( \frac{a_l y - 1}{\sqrt{a_l^2 + 1 - 2a_l y}} \right)
\]

(112)

\[
\frac{\partial}{\partial y} \left( F(1, y, a_l) - F(1, y, a_{l-1}) \right) = \begin{cases} 
\frac{a_l^2 - 1}{\sqrt{1 - y^2(a_l^2 + 1 - 2a_l y)}} > 0 & l \geq 3 \\
0 & l = 2
\end{cases}
\]

(113)

\[
\frac{\partial}{\partial t} \left( F(1, y, t) - F(1, y, t^{-1}) \right) = \frac{2\sqrt{1 - y^2}}{t^2 + 1 - 2ty} > 0.
\]

(114)

Therefore the numbers (115) depending on \( \varepsilon \in (0, 1) \) and \( l \geq 2 \) satisfy (116), (117), (118):

\[
K_\varepsilon(l) = \arccos \left( \frac{\cos(\pi \varepsilon) - a_l}{\sqrt{a_l^2 + 1 - 2a_l \cos(\pi \varepsilon)}} \right) - \arccos \left( \frac{a_l \cos(\pi \varepsilon) - 1}{\sqrt{a_l^2 + 1 - 2a_l \cos(\pi \varepsilon)}} \right)
\]

(115)
From Proposition 7.4 (a), (b), (e) we see that

\[ \epsilon \in (0, +1) \Rightarrow K_\epsilon(2) = 0 \]  \hspace{1cm} (116)

\[ l \in \mathbb{N}_{\geq 3} \quad 0 < u < v < +1 \Rightarrow K_u(l) > K_v(l) \]  \hspace{1cm} (117)

\[ 0 < \epsilon < 1 \quad 2 \leq l_1 < l_2 \in \mathbb{N}_{\geq 2} \Rightarrow K_\epsilon(l_1) < K_\epsilon(l_2) \]  \hspace{1cm} (118)

\[ \lim_{l \to +\infty} K_\epsilon(l) = \pi(1 - \epsilon). \]  \hspace{1cm} (119)

The inequality (111) and the derivative (113) imply that for \( \epsilon \in (0, +1) \) and \( l \geq 2 \) holds:

\[ \sup_{(x, y) \in (0, +\infty) \times (-1, \cos(\pi \epsilon))} \left\{ F(x, y, a_l) - F(x, y, a_l^{-1}) \right\} = K_\epsilon(l), \]  \hspace{1cm} (120)

Note that \( \sup_{(x, y) \in (0, +\infty) \times (-1, 1)} \{ F(x, y, a_l) - F(x, y, a_l^{-1}) \} \) is always equal to \( \pi \)

independently on \( l \geq 3 \) as opposed to \( K_\epsilon(l) \), which is strictly increasing on \( l \).

Finally we note that for \( \epsilon = 1/2 \) the expression (115) takes a simple form (recall

that \( l = \frac{a_l^2 + 1}{a_l} \):\(^6\) \( K_1(l) = \arccos \left( \frac{2}{l} \right) \). and from Proposition 7.7 follows (12).

Now we can compute \( \| D^b(K(l)) \|_\epsilon \).

**Proposition 7.7** Let \( \epsilon \in (0, 1), \ l \geq 2, \) and let \( K_\epsilon(l) \) be as in (115). Then

\( \| D^b(K(l)) \|_\epsilon = K_\epsilon(l) \).

**Proof** From Proposition 7.4 (a), (b), (e) we see that \( P_\sigma \) is not dense in \( S^1 \) for all \( \sigma \),

and (38) reduces to the following formula:

\[
\| D^b(K(l)) \|_\epsilon = \sup \left\{ \frac{\text{vol} \left( \frac{P'_\sigma}{P_\sigma} \right)}{2} : \sigma \in \mathcal{Z} \text{ and there exists } j \in \mathcal{Z} \text{ such that } \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) > \epsilon \right\}
\]

\[
= \sup \left\{ \frac{\text{vol} \left( \frac{P'_\sigma}{P_\sigma} \right)}{2} : \sigma \in \bigcup_{j \in \mathbb{Z}} \{ x \in \mathcal{Z} : \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) > \epsilon \} \right\}
\]

\[
= \sup \left\{ \frac{\text{vol} \left( \frac{P'_\sigma}{P_\sigma} \right)}{2} : \sigma \in \mathcal{Z} \text{ and } \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) > \epsilon \ : j \in \mathbb{Z} \right\}.
\]

By using (108) and (120) we will show that for all \( j \in \mathbb{Z} \) holds:

\[
\| D^b(K(l)) \|_\epsilon = \sup \left\{ \frac{\text{vol} \left( \frac{P'_\sigma}{P_\sigma} \right)}{2} : \sigma \in \mathcal{Z} \text{ and } \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) > \epsilon \right\} = K_\epsilon(l)
\]  \hspace{1cm} (121)

and then the proposition follows. Recalling Proposition 7.2 we see that \( \sigma \in \mathcal{Z} \) and

\[ \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) > \epsilon \text{ iff } s_j, s_{j+1} \in \sigma^{ss} \text{ and } \epsilon < \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) < 1, \]

furthermore

\(^6\) One shows this using the equality \( \arccos(x) - \arccos \left( \sqrt{1-x^2} \right) \) which holds for \( 0 \leq x \leq 1/\sqrt{2} \).
restricting the map (79) to the set of stability conditions \( \sigma \) with \( s_j, s_{j+1} \in \sigma^{ss} \) and \( \varepsilon < \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) < 1 \) we see that the set of pairs \((x_j(\sigma), y_j(\sigma))\) from (108) for these \( \sigma \) is:

\[
\{ (x_j(\sigma), y_j(\sigma)) : \sigma \in \mathcal{Z} \text{ and } \phi_\sigma(s_{j+1}) - \phi_\sigma(s_j) > \varepsilon \}
\]

(122)

Combining the latter equality with (108) and (120) leads to (121).

The latter Proposition and (118) imply (11).

8 The inequality \( \| \langle E_1, E_2 \rangle \|_\varepsilon \geq K_\varepsilon (\text{hom}^{\min}(E_1, E_2)) \)

In this section we derive a formula, which will help us to compute other norms. To that end it is useful to extend the definition of \( K_\varepsilon(l) \) in (115) by postulating \( K_\varepsilon(0) = K_\varepsilon(1) = 0 \). Recall that the notation \( \text{hom}^{\min}(E_1, E_2) \) is explained in (14); this is the dimension of \( \text{Hom}^i(E_1, E_2) \) for the smallest \( i \) such that \( \text{Hom}^i(E_1, E_2) \neq 0 \), if there is no such \( i \) \( \text{hom}^{\min}(E_1, E_2) \) is by definition 0.

**Proposition 8.1** Let \( T \) be a proper category, and let \((E_1, E_2)\) be any exceptional pair in it. Then

\[
\| \langle E_1, E_2 \rangle \|_\varepsilon \geq K_\varepsilon \left( \text{hom}^{\min}(E_1, E_2) \right) \text{ for } \varepsilon \in (0, 1).
\]

(123)

**Proof** We can assume that \( \text{hom}^{\leq 0}(E_1, E_2) = 0 \) and \( l = \text{hom}^1(E_1, E_2) \neq 0 \), and under these assumptions we have to show that

\[
\| \langle E_1, E_2 \rangle \|_\varepsilon \geq K_\varepsilon (l).
\]

(124)

Let \( D \) be the triangulated subcategory \( \langle E_1, E_2 \rangle \). The assumptions on \( (E_1, E_2) \) are the same as in the definition of an \( l \)-Kronecker pair, [21, Definition 3.20], and we can apply [21, Lemma 3.19, Corollary 3.21] to it. In particular the extension closure \( A \) of \( (E_1, E_2) \) is a heart of a bounded t-structure in \( D \) with simple objects \( E_1, E_2, \) and any stability condition \( \sigma = (Z, \mathcal{P}) \in \mathbb{H}^A \subset \text{Stab}(D) \) with \( \arg(Z(E_1)) > \arg(Z(E_2)) \) satisfies \( P^D_\sigma = R_{v, \Delta_{l+}}, \) where \( v = (Z(E_1), Z(E_2)) \). The arguments in the beginning of the proof of Lemma 4.7 show that for each \( v \in \mathbb{H}^2 \) there exists unique \( \sigma = (Z, \mathcal{P}) \in \mathbb{H}^A \) with \( v = (Z(E_1), Z(E_2)) \) and that \( \sigma \) is full. For any \( 0 < \mu \) such that \( \mu + \varepsilon < 1 \) choose the vector \(( -1, \exp(i\pi(\varepsilon + \mu)) ) = v_\mu \), and denote by \( \sigma_\mu \) the stability condition \( \sigma_\mu = (P_\mu, Z_\mu) \in \mathbb{H}^A \) with \( (Z_\mu(E_1), Z_\mu(E_2)) = v_\mu \). The given arguments ensure that \( \sigma_\mu \) is full and \( P^D_{\sigma_\mu} = R_{v_\mu, \Delta_{l+}} \). Using the formula for \( R_{v_\mu, \Delta_{l+}} \) in Lemma 7.5 for the given \( v_\mu \) one derives:

\[
\frac{\text{vol}(P^D_{\sigma_\mu})}{2} = \frac{\text{vol}(R_{v_\mu, \Delta_{l+}})}{2} = K_{\varepsilon + \mu}(l),
\]

(125)
where $K_{ε+μ}(l)$ is in (115). Note that the arc exp $(iπ[μ/2, ε + μ/2])$ is in the complement of $P_{τ}^{D}$ and therefore $σ_ε \in \text{Stab}_b(D)$. Now from the very Definition 4.11 we see that $∥D∥_ε ≥ K_{ε+μ}(l)$ for any small enough positive $μ$, letting $μ → 0$ we derive the desired $∥D∥_ε ≥ K_ε(l)$. □

**Corollary 8.2** Let $E = (E_0, E_1, \ldots, E_n)$ be an exceptional collection in a proper triangulated category $T$. Then for any $0 ≤ i < j ≤ n$ we have $∥\langle E\rangle∥_ε ≥ K_ε(\text{hom}^{\text{min}}(E_i, E_j))$.

**Proof** Take $0 ≤ i < j ≤ n$. By mutating the sequence $E$ (see Remark 7.1) one can get a sequence $E'$ of the form $E' = (E_i, E_j, C_2, \ldots, C_n)$ such that $\langle E\rangle = \langle E'\rangle$. Corollary 6.3 implies $∥\langle E\rangle∥_ε = ∥\langle E'\rangle∥_ε ≥ ∥\langle E_i, E_j\rangle∥_ε$, and due to Proposition 8.1 we get $∥\langle E_i, E_j\rangle∥_ε ≥ K_ε(\text{hom}^{\text{min}}(E_i, E_j))$. □

**Corollary 8.3** Let $T$ be a proper triangulated category such that for each $l ∈ \mathbb{N}$ there exists a full exceptional collection $(E_0, E_1, \ldots, E_n)$ and integers $0 ≤ i < j ≤ n$ for which $\text{hom}^{\text{min}}(E_i, E_j) ≥ l$. Then $∥T∥_ε = π(1 - ε)$ for any $ε ∈ (0, 1)$.

**Proof** The given property of $T$ combined with Corollary 8.2 amounts to $∥T∥_ε ≥ K_ε(l)$ for each $l ≥ 1$ (Recall also 118). Now from (119) and Remark 4.14 we obtain $∥T∥_ε = π(1 - ε)$. □

**Corollary 8.4** Let $T$ be a proper category, and let $0 < ε < 1$.

(a) If $∥T∥_ε = 0$, then for any full exceptional collection $E = (E_0, E_1, \ldots, E_n)$ and for any $0 ≤ i < j ≤ n$ we have $\text{hom}^{\text{min}}(E_i, E_j) ≤ 2$.

(b) If $∥T∥_ε ≤ K_ε(l)$, $l ≥ 2$, then for any full exceptional collection $E = (E_0, E_1, \ldots, E_n)$ and for any $0 ≤ i < j ≤ n$ we have $\text{hom}^{\text{min}}(E_i, E_j) ≤ l$.

(c) If $∥T∥_ε < π(1 - ε)$, then there exists $l ∈ \mathbb{N}$ such that for any full exceptional collection $E = (E_0, E_1, \ldots, E_n)$ and for any $0 ≤ i < j ≤ n$ we have $\text{hom}^{\text{min}}(E_i, E_j) ≤ l$.

We will apply Corollary 8.3 to various examples. More precisely we will show that

**Proposition 8.5** In the following examples of triangulated categories are satisfied the conditions of Corollary 8.3. In particular $∥T∥_ε = (1 - ε)π$ for any $T$ in this list of examples.

(a) $D^b(Q)$, where $Q$ is an acyclic quiver, s.t. there exists a subset $A \subset V(Q)$ such that the quiver $Q_A$ is affine and there exists a vertex $v ∈ V(Q)$ such that $v$ is a source or a sink in $Q_{A∪\{v\}}$ (see Definition 8.6 for the terminology)

(b) $D^b(\mathbb{P}^n)$, $n ≥ 2$;

(c) $D^b(\mathbb{P}^1 × \mathbb{P}^1)$;

(d) $D^b(\mathbb{F}_m)$, $m ≥ 0$

(e) $D^b(X)$, where $X$ is a smooth algebraic variety obtained from $\mathbb{P}^n$, $n ≥ 2$, or from $\mathbb{P}^1 × \mathbb{P}^1$, or from $\mathbb{F}_m$, $m ≥ 0$ by a sequence of blow ups at finite number of points;

(f) $D^b(S)$, where $S$ is any smooth complete rational surface

---

7 Where $\mathbb{F}_m$ is the $m$-th Hirzebruch surface

8 In particular any smooth projective surface.
Definition 8.6 For any quiver $Q$ and any subset $A \subset V(Q)$ we denote by $Q_A$ the quiver whose vertices are $A$ and whose arrows are those arrows of $Q$ whose initial and final vertex is in $A$. A vertex $v \in V(Q)$ is called adjacent to $A$ if there exists an arrow in $Q$ starting at $v$ and ending at a vertex of $A$ or an arrow starting at a vertex of $A$ and ending at a $v$.

Proof of Proposition 8.5 (a) Let $l \geq 3$. By [21, Corollary 3.36] for any $l \geq 3$ there exists a an exceptional pair $(E_0, E_1)$ in $D^b(Q)$ such that $\text{hom}^{\min}(E_0, E_1) \geq l$. In [17] is shown that $(E_0, E_1)$ can be extended to a full exceptional collection. Therefore we can apply Corollary 8.3 to $D^b(Q)$.

Now we present one method (Lemma 8.8) to obtain $l$-Kronecker pairs with arbitrary big $l$ as part of full exceptional collections, i.e. method to obtain the conditions of Corollary 8.3. This method relies on full exceptional collections in which a triple remains strong after certain mutations (see (c) in the statement of Lemma 8.8). In [9] a strong exceptional collection $E$ which remains strong under all mutations is called non-degenerate. Furthermore in [9] are defined so called geometric exceptional collections and [9, Corollary 2.4] says that geometricity implies non-degeneracy. Furthermore, [9, Proposition 3.3] claims that a full exceptional collection of length $m$ of coherent sheaves on a smooth projective variety $X$ of dimension $n$ is geometric if and only if $m = n + 1$. In particular it follows:

Remark 8.7 The full exceptional collection $E = \{ \mathcal{O}, \mathcal{O}(1), \ldots, \mathcal{O}(n) \}$ in $D^b(\mathbb{P}^n)$ introduced by Beilinson [3] is geometric and therefore non-degenerate, whereas the well known (see [24, 38]) strong full exceptional collection of line bundles $(\mathcal{O}(0, 0), \mathcal{O}(0, 1), \mathcal{O}(1, 0), \mathcal{O}(1, 1))$ in $D^b(\mathbb{P}^1 \times \mathbb{P}^1)$ is not geometric.

That’s why the method of Lemma 8.8 is readily applied to $D^b(\mathbb{P}^n)$, whereas applying it to $D^b(\mathbb{P}^1 \times \mathbb{P}^1)$ requires some additional arguments to ensure (c) in Lemma 8.8.

Lemma 8.8 Let $T$ be a proper triangulated category and $\varepsilon \in (0, 1)$. Let $E = (F_0, F_1, F_2, E_3, \ldots, E_n)$ be a full exceptional collection with $n \geq 3$. Let $\{F_i\}_{i \in \mathbb{N}}$ be a sequence starting with $F_0, F_1, F_2$ and $F_{i+1} = RF_i(F_{i-1})$ for $i \geq 2$. If the following three properties hold:

(a) $\text{hom}(F_0, F_1) < \text{hom}(F_0, F_2)$;
(b) $l = \text{hom}(F_1, F_2) \geq 2$;
(c) $(F_0, F_i, F_{i+1})$ is strong for all $i \geq 1$, then $T$ satisfies the condition of Corollary 8.3 and $\|T\|_\varepsilon = \pi(1 - \varepsilon)$.

Proof Now (71) becomes

$$F_{i-1} \xrightarrow{\text{coseq}} F_i \xrightarrow{\text{Hom}^*} \text{Hom}^*(F_{i-1}, F_i) \otimes F_i \rightarrow RF_i(F_{i-1}) = F_{i+1} \quad i \geq 2. \quad (126)$$

Since the property of being full is preserved under mutations, it follows that $(F_0, F_{i-1}, F_i, E_3 \ldots, E_n)$ is full for each $i \geq 2$. We will show that (127) holds, and then our $T$ satisfies the conditions of Corollary 8.3, hence $\|T\|_\varepsilon = \pi(1 - \varepsilon)$.

$$i \in \mathbb{N}_{\geq 2} \Rightarrow \text{hom}(F_0, F_{i-1}) < \text{hom}(F_0, F_i) \quad (127)$$
To show (127) we first note that due to (c) we have \( \text{hom}^k(F_{i-1}, F_i) = 0 \) for each \( k \neq 0 \) and each \( i \geq 2 \) and it follows that (see e.g. [9, Example 2.7]) \( l = \text{hom}(F_1, F_2) = \text{hom}(F_i, F_{i+1}) \) for each \( i \geq 2 \) and then (126) has the form:

\[
F_{i-1} \xrightarrow{\text{coh}_{F_{i-1}, F_i}} F_i \xrightarrow{F_i^{\oplus l}} F_{i+1} \quad i \geq 2.
\] (128)

In (a) we are given \( \text{hom}(F_0, F_{i-1}) < \text{hom}(F_0, F_i) \) for \( i = 2 \) and we will show (127) by induction. Indeed, since \( (F_0, F_{i-1}, F_i) \) is a strong exceptional collection for each \( i \geq 2 \), applying \( \text{Hom}(F_0, \_ ) \) to (128) yields short exact sequences between finite dimensional vector spaces:

\[
0 \rightarrow \text{Hom}(F_0, F_{i-1}) \rightarrow \text{Hom}(F_0, F_i)^{\oplus l} \rightarrow \text{Hom}(F_0, F_{i+1}) \rightarrow 0, \quad i \geq 2.
\] (129)

The obtained exact sequences and \( l \geq 2 \) imply:

\[
\text{hom}(F_0, F_{i+1}) = l \text{hom}(F_0, F_i) - \text{hom}(F_0, F_{i-1}) \geq 2 \text{hom}(F_0, F_i) - \text{hom}(F_0, F_{i-1})
= \text{hom}(F_0, F_i) + (\text{hom}(F_0, F_i) - \text{hom}(F_0, F_{i-1})),
\] (130)

hence for \( i \geq 2 \) the inequality \( \text{hom}(F_0, F_i) > \text{hom}(F_0, F_{i-1}) \) implies \( \text{hom}(F_0, F_{i+1}) > \text{hom}(F_0, F_i) \). The lemma is proved. \( \square \)

**Proof of Proposition 8.5 (b)** In Remark 8.7 is given a full strong exceptional collection \( E \) on \( \mathbb{D}^b(\mathbb{P}^n) \) which remains strong under all mutations. Using [9, Example 2.9] one computes \( \text{hom}(\mathcal{O}, \mathcal{O}(1)) = \text{hom}(\mathcal{O}(1), \mathcal{O}(2)) = n + 1 < \text{hom}(\mathcal{O}, \mathcal{O}(2)) = \frac{(n+1)(n+2)}{2} \). Therefore we can apply Lemma 8.8 and the corollary follows. \( \square \)

**Proof of Proposition 8.5 (c)** Let us denote here \( \mathcal{T} = \mathbb{D}^b(\mathbb{P}^1 \times \mathbb{P}^1) \). Exceptional collections in \( \mathcal{T} \) have been studied in [38] and [24]. In particular the full strong exceptional collection \( (\mathcal{O}(0, 0), \mathcal{O}(0, 1), \mathcal{O}(1, 0), \mathcal{O}(1, 1)) \) mentioned in Remark 8.7 satisfies \( \text{hom}(\mathcal{O}(0, 0), \mathcal{O}(0, 1)) = \text{hom}(\mathcal{O}(0, 1), \mathcal{O}(1, 1)) = 2 \) and \( \text{hom}(\mathcal{O}(0, 0), \mathcal{O}(1, 1)) = 4 \) (see [35, p. 3] or [8, Example 6.5]). After one mutation we get a full exceptional collection \( (F_0, F_1, F_2, E_3) \) in which \( (F_0, F_1) \) is strong, \( \text{hom}(F_0, F_1) < \text{hom}(F_0, F_2) \), and \( \text{hom}(F_1, F_2) = 2 \). Let \( \{F_i\}_i \in \mathbb{N} \) be a sequence starting with \( F_0, F_1, F_2 \) and \( F_{i+1} = R_1(F_i) \) for \( i \geq 2 \). To apply Lemma 8.8 and deduce that \( \|\mathcal{T}\|_\varepsilon = \pi(1 - \varepsilon) \) we need to show that \( (F_0, F_i, F_{i+1}) \) is strong for all \( i \geq 1 \).

From [24, Proposition 5.3.1, Theorem 3.3.1.] it follows that:

*For each exceptional pair \((E, F)\) in \( \mathcal{T} \) there is at most one

\[
i \in Z \text{ with } \text{hom}^i(E, F) \neq 0.
\] (131)

From the way we defined \( \{F_i\}_i \in \mathbb{N} \) it follows (see e.g. [9, Example 2.7]) \( 2 = \text{hom}(F_1, F_2) = \text{hom}(F_{i-1}, F_i) = \text{hom}(F_i, F_{i+1}) \) for all \( i \geq 2 \), hence taking into
account (131), to show that \((F_0, F_i, F_{i+1})\) is strong for all \(i \geq 1\) suffices to show that \(\text{hom}(F_0, F_i) \neq 0\) for each \(i \geq 1\). Now (71) becomes distinguished triangle

\[
\begin{align*}
F_{i-1} \xrightarrow{\text{cov}} & F_i \xrightarrow{F_i^{\otimes 2}} F_{i+1} \xrightarrow{F_{i+1}[1]} i \geq 2. \quad (132)
\end{align*}
\]

We have \(0 < \text{hom}(F_0, F_1) < \text{hom}(F_0, F_2)\). Assume that for some \(i \geq 2\) holds

\[
0 < \text{hom}(F_0, F_i) < \cdots < \text{hom}(F_0, F_{i-1}) < \text{hom}(F_0, F_i) \quad (133)
\]

we will show that this implies \(\text{hom}(F_0, F_i) < \text{hom}(F_0, F_{i+1})\) and by induction the corollary follows. Applying \(\text{Hom}(F_0, \_)_\text{\_}\) to (132) and since \(\text{hom}^k(F_0, F_{i-1}) = \text{hom}^k(F_0, F_i) = 0\) for \(k \neq 0\) one easily deduces that \(\text{hom}^k(F_0, F_{i+1}) = 0\) for \(k \notin \{-1, 0\}\). If \(\text{hom}^{-1}(F_0, F_{i+1}) \neq 0\), then by (131) it follows that \(\text{hom}(F_0, F_{i+1}) = 0\) and applying \(\text{Hom}(F_0, \_)_\text{\_}\) to (132) yields an exact sequence of vector spaces:

\[
0 \longrightarrow \text{Hom}^{-1}(F_0, F_{i+1}) \longrightarrow \text{Hom}(F_0, F_{i-1}) \longrightarrow \text{Hom}(F_0, F_i)^{\otimes 2} \longrightarrow \text{Hom}(F_0, F_{i+1}) = 0,
\]

which contradicts (133). Therefore \(\text{hom}^{-1}(F_0, F_{i+1}) = 0\) and \(\text{hom}^k(F_0, F_{i+1}) = 0\) for \(k \neq 0\). Now we apply \(\text{Hom}(F_0, \_)_\text{\_}\) to (132) again and get a short exact sequence as in (128) which by the same computation as in (130) implies \(\text{hom}(F_0, F_{i+1}) > \text{hom}(F_0, F_i)\), thus we proved the corollary. \(\square\)

**Lemma 8.9** Let \(X\) be a smooth algebraic variety s. t. \(D^b(X)\) satisfies the conditions of Corollary 8.3. Let \(\tilde{X}\) be obtained from \(X\) by blowing up a point. Then \(D^b(\tilde{X})\) satisfies the conditions of Corollary 8.3 as well.

**Proof** [7, Theorem 4.2] ensures that there is a semi-orthogonal decomposition

\[D^b(\tilde{X}) = \langle T_1, T_2, \ldots, T_k, D^b(X) \rangle,\]

where \(T_i\) is equivalent to \(D^b(\text{point})\) for \(i = 1, 2, \ldots, k\), which implies that \(T_i\) is generated by an exceptional object for each \(i\). Now it is clear that the full exceptional sequences of \(D^b(X)\) ensuring the conditions of Corollary 8.3 extend to full exceptional collections on \(D^b(\tilde{X})\), so these conditions are satisfied in \(D^b(\tilde{X})\) as well. \(\square\)

**Proof of Proposition 8.5 (d), (e), and (f)** Since \(\mathbb{F}_0 = \mathbb{P}^1 \times \mathbb{P}^1\) and \(\mathbb{F}_1 = \mathbb{P}^2\) blown up at a point, then the cases \(a = 0, 1\) are contained in Proposition 8.5 (a), (b), and Lemma 8.9. In [28] they construct families of full exceptional collections of invertible sheaves on \(D^b(\mathbb{F}_a)\) for any \(a\). To show that their exceptional collections furnish the conditions of Corollary 8.3 we just need to combine some results in [28]. First adopt here some notations and terminology from [28]: \(P, Q\) denotes basis of \(\text{Pic}(\mathbb{F}_a)\) (see [28, Section 4, p.1224]) s.t.

\[
P \cdot Q = 1, Q^2 = a, P^2 = 0. \quad (135)
\]

Hille and Perling study certain sequences of Cartier divisors on a rational surfaces \(X\) which they call toric systems. Furthermore a toric system \(A_1, A_2, \ldots, A_n\) is called
strongly exceptional (see [28, Definition 3.6]), if they generate a sequence of invertible sheaves

\[ O_X, O_X(A_1), O_X(A_1 + A_2), \ldots, O_X \left( \sum_{i=1}^{n-1} A_i \right), \]

which is strong exceptional. For such a toric system each divisor \( A_j \) is numerically left orthogonal [28, Definition 3.1 (a)], which means that \( \chi(-A_j) = 0 \). Indeed, we have

\[ \text{Ext}^k \left( O_X \left( \sum_{i=1}^j A_i \right), O_X \left( \sum_{i=1}^{j-1} A_i \right) \right) = \{0\} \]

for each \( k \in \mathbb{Z} \), since the sequence is exceptional, and on the other hand

\[ \text{Ext}^k \left( O_X \left( \sum_{i=1}^j A_i \right), O_X \left( \sum_{i=1}^{j-1} A_i \right) \right) \cong H^k(O_X(-A_j)) = \{0\} \]

(see e.g. [28, the beginning of Section 3]), and hence \( \chi(-A_j) = 0 \). Note also that since the sequence is strong it follows that \( \chi(A_j) = \dim(H^0(O_X(A_j))) = \text{hom} \left( O_X \left( \sum_{i=1}^{j-1} A_i \right), O_X \left( \sum_{i=1}^j A_i \right) \right) \). On the other hand, having that \( A_j \) is numerically left orthogonal and using [28, Lemma 3.3 (i)] we derive:

\[ \text{hom} \left( O_X \left( \sum_{i=1}^{j-1} A_i \right), O_X \left( \sum_{i=1}^j A_i \right) \right) = \chi(A_j) = -K_X.A_j \]  \hspace{1cm} (136)

[28, Proposition 5.2] proves that \( P, sP + Q, P, -(a+s)P + Q \) is a strongly exceptional toric system on \( \mathbb{P}_a \) when \( s \geq -1 \). If we denote by \( E_1^s, E_2^s, E_3^s, E_4^s \) the corresponding strong exceptional collection, then using the formula (136) and the property of toric system, that \( \sum_{i=1}^n A_i = -K_X \) (see [28, p. 1233 down]), and also the equalities (135) we compute:

\[ \text{hom}(E_2^s, E_3^s) = -K_X.(sP + Q) = (2(P + Q) - aP).(sP + Q) = 2s = a + 2s \]  \hspace{1cm} (137)

Thus we see that \( \text{hom}(E_2^s, E_3^s) \) can be done arbitrary big. The sequence \( E_1^s, E_2^s, E_3^s, E_4^s \) is already shown to be full (see [28, Theorem 5.8.], also [28, the beginning of the proof of Theorem 8.6.] or [29, Proposition 2.1]). Part (d) is proved. Part (e) follows by recursively applying Lemma 8.9 and the already proven cases. Part (f) reduces to part (e), since any smooth complete rational surface \( S \) can be constructed after applying a finite sequence of blow ups starting with \( \mathbb{P}^2 \) of \( \mathbb{F}_a \), \( a \geq 0 \) (see e.g. [28, the beginning of Section 4, p. 1243]). \( \square \)
9 The inequality \( \| T_1 \oplus \cdots \oplus T_n \|_\varepsilon < \pi(1 - \varepsilon) \)

The goal of this section is to prove the following:

**Proposition 9.1** Let \( n \geq 1 \), let \( l_i \geq 1 \), \( i = 1, 2, \ldots, n \) be a sequence of integers, and let \( 0 < \varepsilon < 1 \). Then for any orthogonal decomposition of the form \( T = T_1 \oplus T_2 \oplus \cdots \oplus T_n \), where \( T_i \cong D^b(K(l_i)) \), holds \( \|T\|_\varepsilon < \pi(1 - \varepsilon) \). Furthermore \( \|T\|_\varepsilon > 0 \) iff \( l_i \geq 3 \) for some \( 1 \leq i \leq n \).

Before going to the proof of this proposition we prove some facts for the case \( l \geq 3 \) and denote \( T_i = D^b(K(l)) \). We will use notations and results from Sect. 7. The first step is:

**Lemma 9.2** For \( \sigma \notin \mathcal{Z} \) the set \( P_{\sigma}^l = \overline{P_{\sigma}^l} \) is finite. Otherwise, for \( \sigma \in \mathcal{Z} \), we use the description of the set \( \overline{P_{\sigma}^l} \) as in Proposition 7.4 (88), (89), (90).

For any \( 0 < \varepsilon < 1 \) there exists \( M_{l, \varepsilon} > 0 \) such that for any \( \sigma \in \mathcal{Z} \) and for any \( j \in \mathbb{Z} \):

\[
\phi_{\sigma}(s_{j+1}) - \phi_{\sigma}(s_j) > \varepsilon \quad \Rightarrow \\
\frac{v_{\sigma} - u_{\sigma}}{u_{\sigma} - \pi \phi_{\sigma}(s_{j+1}|-1|)} \leq M_{l, \varepsilon} \frac{v_{\sigma} - u_{\sigma}}{\pi \phi_{\sigma}(s_j) - v_{\sigma}} \leq M_{l, \varepsilon}.
\]

(138)

**Proof** The part of the lemma which is not contained in Proposition 7.4 are the inequalities (138). So, let us chose \( \sigma \in \mathcal{Z}, \, j \in \mathbb{Z} \) and \( 0 < \varepsilon < 1 \) and assume that \( \phi_{\sigma}(s_{j+1}) - \phi_{\sigma}(s_j) > \varepsilon \). In terms of the function (107) we can rewrite (91) as follows:

\[
\frac{v_{\sigma} - u_{\sigma}}{u_{\sigma} - \pi \phi_{\sigma}(s_{j+1}|-1|)} = \frac{F(x, y, a_t) - F(x, y, a_t^{-1})}{F(x, y, a_t^{-1}) - \arccos(y)}; \\
\frac{v_{\sigma} - u_{\sigma}}{\pi \phi_{\sigma}(s_j) - v_{\sigma}} = \frac{F(x, y, a_t) - F(x, y, a_t^{-1})}{\pi - F(x, y, a_t)}
\]

(139)

where (recall that \( \sigma \in \mathcal{Z} \) implies \( \phi_{\sigma}(s_{j+1}) - \phi_{\sigma}(s_j) < 1 \)):

\[
0 < x = \frac{|Z(s_{j+1})|}{|Z(s_j)|} - 1 < y = \cos \left( \pi (\phi_{\sigma}(s_{j+1}) - \phi_{\sigma}(s_j)) \right) < \cos(\pi \varepsilon):
\]

(140)

For any \( a \in (0, +\infty), \, b \in (-1, +1) \) the differentiable functions \( (0, +\infty) \ni t \mapsto F(a, b, t) \) and \( (0, +\infty) \ni t \mapsto F(t, b, a) \) can be extended uniquely to continuous functions in \([0, +\infty) \) having values \( \arccos(b) \) and \( \pi \) at 0, respectively, and therefore we can apply the mean value theorem to these functions. More precisely, if \( h : [0, +\infty) \to \mathbb{R} \) is a function obtained in such a way, then for any \( 0 \leq \alpha < \beta < +\infty \) there exists \( \alpha < t < \beta \) such that \( h(\beta) - h(\alpha) = (\beta - \alpha)h'(t) \). In particular, for any \( x, \, y \) as in (140) we can represent all the differences in (139) as follows (recall 109):
If $0 < x' < x$ (141) follows.

$$\frac{1}{\pi - F(x, y, a_l)} = \frac{-1}{F(x, y, a_l) - \pi} = \frac{1}{x - a_l \sqrt{1 - y^2}}$$

$$= \frac{a_l^2 + x^2 - 2a_l x' y}{x a_l \sqrt{1 - y^2}}$$

for some $0 < x' < x$ (141)

$$\frac{1}{F(x, y, a_l^{-1}) - \arccos(y)} = \frac{1}{a_l^{-1} x \sqrt{1 - y^2}}$$

$$= \frac{a_l (t^2 + x^2 - 2txy)}{x \sqrt{1 - y^2}}$$

for some $0 < t < a_l^{-1}$ (142)

$$\begin{align*}
F(x, y, a_l) - F(x, y, a_l^{-1}) &= \frac{(a_l - a_l^{-1}) x \sqrt{1 - y^2}}{t^2 + x^2 - 2txy} \\
&\leq \frac{(a_l - a_l^{-1}) x \sqrt{1 - y^2}}{t^2 + x^2 - 2tx \cos(\pi \varepsilon)} \quad \text{for some } a_l^{-1} < t' < a_l.
\end{align*}$$

And now looking back at (139) we deduce:

$$\frac{v_\sigma - u_\sigma}{u_\sigma - \pi \phi_\sigma(s_{j+1}[-1])} \leq \frac{(a_l^2 - 1)(t^2 + x^2 - 2txy)}{t^2 + x^2 - 2tx \cos(\pi \varepsilon)}$$

(144)

$$\frac{v_\sigma - u_\sigma}{\pi \phi_\sigma(s_j) - v_\sigma} \leq \frac{(1 - a_l^{-2})(a_l^2 + x^2 - 2a_l x'y)}{t^2 + x^2 - 2tx \cos(\pi \varepsilon)}$$

(145)

Now since $t^2 + x^2 - 2tx \cos(\pi \varepsilon)$ gets minimal values for $t' = x \cos(\pi \varepsilon)$ (with respect to the variable $t'$) and for $x = t' \cos(\pi \varepsilon)$ (with respect to the variable $x$) we have $t^2 + x^2 - 2tx \cos(\pi \varepsilon) \geq x^2 (1 - \cos^2(\pi \varepsilon)) = x^2 \sin^2(\pi \varepsilon)$ and $t^2 + x^2 - 2tx \cos(\pi \varepsilon) \geq t^2 \sin^2(\pi \varepsilon) \geq a_l^{-2} \sin^2(\pi \varepsilon)$, therefore:

$$t^2 + x^2 - 2tx \cos(\pi \varepsilon) \geq \max \left\{ a_l^{-2}, x^2 \right\} \sin^2(\pi \varepsilon)$$

(146)

and (144), (145) can be continued (recall that $0 < t < a_l^{-1}$ in (142) and $0 < x' < x$ in (141)):

$$\frac{v_\sigma - u_\sigma}{u_\sigma - \pi \phi_\sigma(s_{j+1}[-1])} \leq \frac{(a_l^2 - 1)(t^2 + x^2 - 2txy)}{\max[a_l^{-2}, x^2] \sin^2(\pi \varepsilon)}$$

$$\leq \frac{(a_l^2 - 1)}{\sin^2(\pi \varepsilon)} \sup \left\{ \frac{(t^2 + x^2 - 2txy)}{\max[a_l^{-2}, x^2]} : t \in (0, a_l^{-1}), x \in (0, +\infty) \right\}$$

$$\frac{v_\sigma - u_\sigma}{\pi \phi_\sigma(s_j) - v_\sigma} \leq \frac{(1 - a_l^{-2})(a_l^2 + x^2 - 2a_l x'y)}{\max[a_l^{-2}, x^2] \sin^2(\pi \varepsilon)}$$

$$\leq \frac{(1 - a_l^{-2})}{\sin^2(\pi \varepsilon)} \sup \left\{ \frac{(a_l^2 + x^2 - 2a_l x'y)}{\max[a_l^{-2}, x^2]} : x \in (0, +\infty), \ x' \in (0, x), \ y \in (-1, \cos(\pi \varepsilon)) \right\}$$

hence (138) follows. ☐
Corollary 9.3  For any $\sigma \in \mathcal{Z}$ there is closed $\frac{\text{vol}(\mathcal{P}_\sigma^T)}{2}$-arc $p_\sigma^l \subset \mathcal{P}_\sigma^T$ s.t. $\mathcal{P}_\sigma^T \setminus (p_\sigma^l \cup -p_\sigma^l)$ is countable.

Let $0 < \varepsilon < 1$. For any closed $\varepsilon$-arc $\gamma$ satisfying $P_\sigma^l \cap \gamma = \emptyset$ hold $(p_\sigma^l \cup -p_\sigma^l) \cap (\gamma \cup -\gamma) = \emptyset$ and any (of the four) connected component $c$ of $\mathcal{S}_1 \setminus (\{ p_\sigma^l \cup -p_\sigma^l \cup \gamma \cup -\gamma \} \setminus \gamma)$ restricts $\text{vol}(\mathcal{P}_\sigma^T)$ as follows:

$$c \subset \mathcal{S}_1 \setminus (\{ p_\sigma^l \cup -p_\sigma^l \cup \gamma \cup -\gamma \} \setminus \gamma) \ni \pi_0(c) = \{0\} \Rightarrow \frac{\text{vol}(\mathcal{P}_\sigma^T)}{2} = \text{vol}(p_\sigma^l) \leq M_{l,\varepsilon} \text{vol}(c) \quad (147)$$

where $M_{l,\varepsilon}$ is as in Lemma 9.2.

Proof  For $\sigma \in \mathcal{Z}$, the set $\mathcal{P}_\sigma^T$ is as described in (88), (89), (90) and then we can choose $p_\sigma^l$ to be $\exp(\i [u_\sigma, v_\sigma])$ and $\mathcal{S}_1$ can be divided as follows (for any $j \in \mathbb{Z}$):

$$\mathcal{S}_1 = e^{i\pi [\phi_\sigma(s_j,-1), \phi_\sigma(s_{j+1},-1)]} \cup e^{i\pi [\phi_\sigma(s_{j+1},-1), u_\sigma]} \cup p_\sigma^l \cup e^{i(v_\sigma,\pi \phi_\sigma(s_j))}$$

$$\cup -e^{i\pi [\phi_\sigma(s_j,-1), \phi_\sigma(s_{j+1},-1)]} \cup -v_\sigma \cup p_\sigma^l \cup e^{i(v_\sigma,\pi \phi_\sigma(s_j))}$$

(148)

Furthermore, let $\gamma$ be a closed $\varepsilon$-arc with $P_\sigma^l \cap \gamma = \emptyset$, then using (89) one easily sees that $\gamma \subset \exp(\i \pi [\phi_\sigma(s_j, \phi_\sigma(s_{j+1}))])$ or $-\gamma \subset \exp(-\i \pi [\phi_\sigma(s_j, \phi_\sigma(s_{j+1}))])$ for some $j \in \mathbb{Z}$ and therefore $\pi(\phi_\sigma(s_{j+1}) - \phi_\sigma(s_j)) > \text{vol}(\gamma) = \pi \varepsilon$, hence by Lemma 9.2 follow the inequalities (138) and

$$\gamma \subset e^{i\pi [\phi_\sigma(s_j,-1), \phi_\sigma(s_{j+1},-1)]} \quad \text{or} \quad -\gamma \subset e^{i\pi [\phi_\sigma(s_j,-1), \phi_\sigma(s_{j+1},-1)]}. \quad (149)$$

Therefore, taking into account the disjoint union (148) we see that the four components of $\mathcal{S}_1 \setminus (\gamma \cup -\gamma \cup p_\sigma^l \cup -p_\sigma^l)$ can be ordered as $c_1, c_2, -c_1, -c_2$ so that: $c_1 \supset e^{i\pi [\phi_\sigma(s_{j+1},-1), u_\sigma]}, c_2 \supset e^{i(v_\sigma,\pi \phi_\sigma(s_j))}$, in particular:

$$\text{vol}(\pm c_1) \geq u_\sigma - \pi \phi_\sigma(s_{j+1},-1) \quad \text{vol}(\pm c_2) \geq \pi \phi_\sigma(s_j) - v_\sigma \quad (150)$$

and the corollary follows from (138). $\square$

Proof of Proposition 9.1  From Remark 4.15 and Sect. 7.3 we see that:

$$\| T_{l_i} \|_\varepsilon = \| D_b(K(l_i)) \|_\varepsilon = K_\varepsilon(l_i) \quad (151)$$

hence the proposition follows for $n = 1$. $\square$

Assume that we have already proved the proposition for $1 \leq n \leq N$. And assume that $T = T_{l_1} \oplus T_{l_2} \oplus \cdots \oplus T_{l_N} \oplus T_{l_{N+1}}$, where $T_{l_i} \equiv D_b(K(l_i))$ and denote by $L$ the set $L = \{l_1, l_2, \ldots, l_N, l_{N+1}\}$. 
If $1 \leq l_j \leq 2$ for some $j$, then $\|T_j\|_g = \|D^b(K(l_j))\|_g = 0$, and the statement follows from the induction assumption, Corollary 5.6, and $\|T_j\|_g = 0$. Therefore we can assume that all integers in $L$ are at least 3. From the induction assumption there exists $\delta > 0$ such that:

$$\delta + X = \pi(1 - \varepsilon), \quad \text{where}$$

$$X = \max \left\{ \|T_{x_1} \oplus T_{x_2} \oplus \cdots \oplus T_{x_j}\|_g : j < N + 1, x_i \in L \text{ for } 1 \leq i \leq j \right\}$$

(152)

Note that due to Remark 4.2, Proposition 5.2 (d), and Corollary 5.5 for any sequence $x_1, x_2, \ldots, x_j$ in $L$ holds:

$$\|T_{x_1} \oplus T_{x_2} \oplus \cdots \oplus T_{x_j}\|_g$$

$$= \sup \left\{ \frac{\text{vol}(\bigcup_{i=1}^{j} P_{\sigma_i}^{l_j})}{2} : \exists \varepsilon \text{-arc } \gamma \text{ s.t. } \forall \sigma_i \in \text{Stab}(D^b(K(x_i))) \text{ and } \emptyset = P_{\sigma_i}^{l_j} \cap \gamma \right\}$$

(153)

Assume now that $\sigma_i \in \text{Stab}(D^b(K(l_i)))$ for $i = 1, \ldots, N + 1$ and that there exists a closed $\varepsilon$-arc $\gamma$ satisfying $\emptyset = P_{\sigma_i}^{l_j} \cap \gamma = \emptyset$ for $i = 1, \ldots, N + 1$. In particular we can represent the circle $\mathbb{S}^1$:

$$\mathbb{S}^1 = \exp(i(\alpha, \beta)) \cup \gamma \cup -\exp(i(\alpha, \beta)) \cup -\gamma \quad \text{disjoint union} \quad (154)$$

where $\alpha \in \mathbb{R}$ and $\beta = \alpha + \pi(1 - \varepsilon)$. If for some $k$ the corresponding $\sigma_k \notin Z_i \subset \text{Stab}(D^b(K(l_k)))$, then by Lemma 9.2 $P_{\sigma_k}^{l_k}$ is finite and taking into account (152), (153) we derive:

$$\frac{\text{vol}(\bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j})}{2} = \frac{\text{vol}(\bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j})}{2} \leq X, \quad (155)$$

otherwise for all $i$ we have $\sigma_i \in Z_i$, and then by Corollary 9.3 $\frac{\text{vol}(\bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j})}{2} = \text{vol} \left( \bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j} \right)$, where $P_{\sigma_i}^{l_j}$ is a closed arc as explained in Corollary 9.3 and we can assume that $P_{\sigma_i}^{l_j} \subset \exp(i(\alpha, \beta))$ for all $i$ (see (154)). There exist $\delta_- > 0, \delta_+ > 0$ such that $\bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j} \subset \exp(i(\alpha + \delta_-, \beta - \delta_+), \exp(i(\alpha + \delta_-, \exp(i(\beta - \delta_+)) \in \bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j}$.

Let $j, k$ be such that $\exp(i(\alpha + \delta_-) \in P_{\sigma_j}^{l_j}$ and $\exp(i(\beta - \delta_+)) \in P_{\sigma_k}^{l_k}$. If we denote $M = \max\{M_{l_i, \varepsilon} : 1 \leq i \leq N + 1\}$, then from Corollary 9.3 we obtain $\text{vol}(P_{\sigma_j}^{l_j}) + \text{vol}(P_{\sigma_k}^{l_k}) \leq M(\delta_+ + \delta_-)$. Since $\bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j} \subset \exp(i(\alpha + \delta_-, \beta - \delta_+))$ it follows that $\delta_+ + \delta_- \leq \pi(1 - \varepsilon) - \text{vol} \left( \bigcup_{i=1}^{N+1} P_{\sigma_i}^{l_j} \right)$, therefore we can write:
\[
\frac{\vol \left( \bigcup_{i=1}^{N+1} p_{l_i}^{l_i} \right)}{2} = \vol \left( \bigcup_{i=1}^{N+1} P_{l_i}^{l_i} \right) - \vol(\bigcup_{i=1, i \neq j, i \neq k}^{N+1} P_{l_i}^{l_i})
\]
\[
\leq M \left( \pi (1 - \varepsilon) - \frac{\vol \left( \bigcup_{i=1}^{N+1} P_{l_i}^{l_i} \right)}{2} \right).
\]
\[
\leq M \left( \pi (1 - \varepsilon) - \frac{\vol \left( \bigcup_{i=1}^{N+1} p_{l_i}^{l_i} \right)}{2} \right) + X
\]
\[
= M \left( \pi (1 - \varepsilon) - \frac{\vol \left( \bigcup_{i=1}^{N+1} p_{l_i}^{l_i} \right)}{2} \right) + X
\]

The obtained inequalities (155), (156), and the formula (153) with \(x_i = l_i\), for \(i = 1, 2, \ldots, N + 1\) show that for a certain set \(Y\) and a real function \(G\) on \(Y\) we have:

\[
\| T_{l_1} \oplus T_{l_2} \oplus \cdots \oplus T_{l_{N+1}} \|_\varepsilon = \sup \{ G(y) : y \in Y \}
\]
\[
\forall y \in Y \quad 0 \leq G(y) \leq \pi (1 - \varepsilon); \quad G(y) \leq M(\pi (1 - \varepsilon) - G(y)) + X.
\]

Now recalling (152) we get \(G(y) \leq M(\pi (1 - \varepsilon) - G(y)) + \pi (1 - \varepsilon) - \delta\) for any \(y \in Y\), which is the same as \(G(y) \leq \pi (1 - \varepsilon) - \frac{\delta}{M+1}\). Therefore the proof completes with the following inequality:

\[
0 < \| T_{l_1} \oplus T_{l_2} \oplus \cdots \oplus T_{l_{N+1}} \|_\varepsilon \leq \pi (1 - \varepsilon) - \frac{\delta}{M+1}.
\]

### 10 Discrete derived categories and their norms

There are categories, in which every heart of a bounded t-structure has finitely many indecomposable objects up to isomorphism. Due to the following lemma the norm of these categories vanishes:

**Lemma 10.1** For any triangulated category \(T\) and any \(a \in \mathbb{R}\) we have:

\[
P^T_\sigma = \{ \pm \exp(i \pi \phi_\sigma(I)) : I \in \sigma^{ss} \cap \mathcal{P}(a, a + 1) \text{ and } I \text{ is } \mathcal{P}(a, a + 1)-\text{indecomposable} \}.
\]

**Proof** From [18, Lemma 3.9] we know that

\[
P^T_\sigma = \{ \exp(i \pi \phi_\sigma(I)) : I \text{ is } T-\text{indecomposable and } I \in \sigma^{ss} \}.
\]

Furthermore, the properties that for any \(j \in \mathbb{Z}\) holds \(I \in \sigma^{ss}\) iff \(I[j] \in \sigma^{ss}\), and that \(\phi_\sigma(I[j]) = \phi_\sigma(I) + j\) whenever \(I \in \sigma^{ss}\) are axioms of Bridgeland, which together with (159) imply
\[
P^\sigma_T = (\pm \exp(i\pi \phi_\sigma(I)) : I \text{ is indecomposable and } I \in \sigma^{ss}\text{ and } \phi_\sigma(I) \in (a, a+1]) \quad (160)
\]

From [22, Lemma 3.7] it follows that an object \( I \in \mathcal{P}(a, a+1) \) is \( T \)-indecomposable iff it is \( \mathcal{P}(a, a + 1) \)-indecomposable, hence the lemma follows. \( \square \)

**Corollary 10.2** Let \( \mathcal{T} \) be a category with phase gap, s.t. every heart of a bounded t-structure has finitely many indecomposable objects up to isomorphism. Then \( \| T \|_\varepsilon = 0 \) for every \( \varepsilon \in (0, 1) \).

**Proof** First recall that for each \( \sigma = (Z, \mathcal{P}) \in \text{Stab}(\mathcal{T}) \) and for any \( a \in \mathbb{R} \) the subcategory \( \mathcal{P}(a, a+1) \) is a heart of a bounded t-structure. From the previous lemma \( P^\sigma_T \) is finite for each \( \sigma \in \text{Stab}(\mathcal{T}) \). Therefore from Definition 39 it follows that \( \| T \|_\varepsilon = 0 \). \( \square \)

In representation theory was introduced a class of triangulated categories with a particularly discrete structure, called Discrete derived categories (Vossieck [42]), they were classified in [4] and thoroughly studied in [14], whereas the topology of the stability spaces on them were studied in [13,37], in particular it was shown that these spaces are all contractible. This class contains the categories \{\( D^b(Q) : Q \) is Dynkin\}, and the discrete derived categories not contained in this list are of the form \( D^b(\Lambda(r, n, m)) \) for \( n \geq r \geq 1 \) and \( m \geq 0 \), where \( \Lambda(r, n, m) \) is the path algebra of the quiver with relations shown on [37, Section 4.3, Figure 1].

**Proposition 10.3** For any discrete derived category \( \mathcal{T} \) (in the sense of [4,42]) and any \( \varepsilon \in (0, 1) \) holds \( \| T \|_\varepsilon = 0 \).

**Proof** [14, Proposition 7.1] says that each heart of a bounded t-structure in \( \mathcal{T} \) has finitely many indecomposable objects and is of finite length. In particular (see Lemma 4.7) \( \mathcal{T} \) has a phase gap and it satisfies the conditions of Lemma 10.2, therefore \( \| T \|_\varepsilon = 0 \). \( \square \)

### 11 Topology on the class of proper triangulated categories with a phase gap

In this section we denote by \( \mathcal{S}' \) the set of all small triangulated categories within a certain universe (a universe which contains the derived categories of representations of algebras) and by \( \mathcal{P}\mathcal{S}' \subset \mathcal{S}' \) we denote the subset of proper categories with finite rank Grothendieck group and with a phase gap. From Proposition 10.3 (see also its proof) it follows that each discrete category is in \( \mathcal{P}\mathcal{S}' \). Furthermore, from [14, Proposition 7.6] it follows that each discrete derived category has a full Exceptional collection. Thus if we denote by \( \mathcal{D}\mathcal{D}\mathcal{R}' \) the subset in \( \mathcal{S}' \) of discrete derived categories, and by \( \mathcal{E}' \) the subset of proper categories with a full exceptional collection, then we have the inclusions: \( \mathcal{D}\mathcal{D}\mathcal{R}' \subset \mathcal{E}' \subset \mathcal{P}\mathcal{S}' \subset \mathcal{S}' \). When we write \( A \cong B \) for \( A, B \in \mathcal{T}' \), we mean an
equivalence between triangulated categories, and by $\mathcal{X} = \mathcal{X}' / \cong$, $\mathcal{P} \mathcal{G} = \mathcal{P} \mathcal{G}' / \cong$, $\mathcal{D} \mathcal{D} \mathcal{K} = \mathcal{D} \mathcal{D} \mathcal{K}' / \cong$ we denote the corresponding sets of equivalence classes and then we have inclusions:

$$\mathcal{D} \mathcal{D} \mathcal{K} \subset \mathcal{E} \subset \mathcal{P} \mathcal{G} \subset \mathcal{X}.$$  

We give first an example of a topology on the largest $\mathcal{X}$ and give evidence that this topology is too coarse.

**Definition 11.1** For any $\mathcal{T} \in \mathcal{X}'$ we denote a subset of $\mathcal{X}'$ as follows:

$$B(\mathcal{T}) = \{ \mathcal{T}' \in \mathcal{X}' : \mathcal{T}' \cong \mathcal{T} \text{ or there is a SOD } \mathcal{T}' = \langle \mathcal{A}, \mathcal{B} \rangle \text{ with } \mathcal{A} \cong \mathcal{T} \}.$$  

By definition we have $B(\mathcal{T}_1) = B(\mathcal{T}_2)$, if $\mathcal{T}_1 \cong \mathcal{T}_2$.

**Lemma 11.2** Let $\mathcal{T}', \mathcal{T}$ be triangulated categories. If $\mathcal{T}' \in B(\mathcal{T})$, then $B(\mathcal{T}') \subset B(\mathcal{T})$. In particular, the family of sets $\{ B(\mathcal{T}) \}_{\mathcal{T} \in \mathcal{X}'}$ is a base of a topology on $\mathcal{X}'$, and the family of sets $\{ B(\mathcal{T})/ \cong \}_{\mathcal{T} \in \mathcal{X}'}$ is a base of a topology on $\mathcal{X}$.

**Proof** Since $\mathcal{T}' \in B(\mathcal{T})$, by definition there is a SOD $\mathcal{T}' = \langle \mathcal{A}, \mathcal{B} \rangle$ with $\mathcal{A} \cong \mathcal{T}$.

Let $\mathcal{T}_1 \in B(\mathcal{T}')$, therefore there is a SOD $\mathcal{T}_1 = \langle \mathcal{C}, \mathcal{D} \rangle$ with $\mathcal{C} \cong \mathcal{T}'$, now the SOD $\mathcal{T}' = \langle \mathcal{A}, \mathcal{B} \rangle$ implies a SOD $\mathcal{C} = \langle \mathcal{A}', \mathcal{B}' \rangle$, where $\mathcal{A}' \cong \mathcal{A} \cong \mathcal{T}$. Therefore we obtain a SOD $\mathcal{T}_1 = \langle \langle \mathcal{A}', \mathcal{B}' \rangle, \mathcal{D} \rangle = \langle \mathcal{A}', \langle \mathcal{B}', \mathcal{D} \rangle \rangle$ with $\mathcal{A}' \cong \mathcal{T}$. i.e. $\mathcal{T}_1 \in B(\mathcal{T})$. \(\square\)

**Lemma 11.3** If $\mathcal{T}$ is indecomposable with respect to semi-orthogonal decompositions, then $[\mathcal{T}] \in \mathcal{X}$ is a closed point w.r. to the topology introduced in Lemma 11.2. If there exists a SOD $\mathcal{T} = \langle \mathcal{A}, \mathcal{B} \rangle$, where $\mathcal{T} \not\cong \mathcal{A}$, then $[\mathcal{T}] \in \mathcal{X}$ is not a closed point in this topology.

**Proof** Let $\mathcal{T}$ be indecomposable and $\mathcal{T} \not\cong \mathcal{T}$, then $\mathcal{T} \notin B(\mathcal{T}')$ by the definition 11.1, therefore $[\mathcal{T}]$ is a closed point indeed.

Assume that there exists a SOD $\mathcal{T} = \langle \mathcal{A}, \mathcal{B} \rangle$ and $\mathcal{T} \not\cong \mathcal{A}$, it follows that $[\mathcal{T}] \in B(\mathcal{A})/ \cong$ and $[\mathcal{T}] \neq [\mathcal{A}]$, therefore all open subsets containing $[\mathcal{A}]$, contain $[\mathcal{T}]$ as well. i.e. $[\mathcal{A}]$ is in the closure of $[\mathcal{T}]$, and it is different from $[\mathcal{T}]$, so $[\mathcal{T}]$ is not a closed point. \(\square\)

**Corollary 11.4** The only closed point in $\mathcal{E}$ w.r. to the topology introduced in Lemma 11.2 (also with respect to the induced on $\mathcal{E}$ topology) is $[\mathcal{T}] = [D^b(\text{point})]$.

**Proof** It is well known that $D^b(\text{point})$ is indecomposable with respect to semi-orthogonal decomposition. Now the corollary follows from Lemma 11.3. \(\square\)

Now we define a refinement of the topology discussed so far, in which we have many closed points, furthermore we have many discrete subsets, in particular the set of discrete derived categories (up to equivalence) will be a discrete subset as well. However this new topology is defined only on $\mathcal{P} \mathcal{G}'$, respectively $\mathcal{P} \mathcal{G}$. 

Definition 11.5 For any $\varepsilon \in (0, 1)$ and any $T \in \mathcal{P} \mathcal{G}'$ we denote
\[ \|T\|^\varepsilon = (1 - \varepsilon)\pi - \|T\|_\pi. \] (163)

For any $T \in \mathcal{P} \mathcal{G}'$, any $\delta > 0$ we denote a subset of $\mathcal{P} \mathcal{G}'$ as follows:
\[ B^\varepsilon_\delta(T) = \{T' \in \mathcal{P} \mathcal{G}' : T' \cong T \text{ or } T' = \langle A, B \rangle \text{ is a SOD} \]
with $A \cong T, B \in \mathcal{P} \mathcal{G}', \|B\|^\varepsilon < \delta \}. \] (164)

By definition we have $B^\varepsilon_\delta(T_1) = B^\varepsilon_\delta(T_2)$, if $T_1 \cong T_2$. Furthermore from Theorem 6.1 it follows that for any $T_1, T_2 \in \mathcal{P} \mathcal{G}'$ and any SOD $T = \langle T_1, T_2 \rangle$ holds:
\[ \|\langle T_1, T_2 \rangle\|^\varepsilon \leq \min\{\|T_1\|^\varepsilon, \|T_2\|^\varepsilon\}. \] (165)

From now on $\varepsilon$ is a real number in $(0, 1)$ and we will write just $B_\delta(T)$ instead of $B^\varepsilon_\delta(T)$.

Lemma 11.6 If $T, T' \in \mathcal{P} \mathcal{G}'$, $\delta > 0$ and $T' \in B_\delta(T)$, then $B_\delta(T') \subseteq B_\delta(T)$ for any $\delta' > 0$. In particular, the family of sets $\{B_\delta(T)\}_{T \in \mathcal{P} \mathcal{G}', \delta > 0}$ is a base of a topology on $\mathcal{P} \mathcal{G}'$, and the family of sets $\{B_\delta(T)/\cong\}_{T \in \mathcal{P} \mathcal{G}', \delta > 0}$ is a base of a topology on $\mathcal{P} \mathcal{G}$.

Proof Since $T' \in B_\delta(T)$, by definition $T' = \langle A, B \rangle$ with $A \cong T, B \in \mathcal{P} \mathcal{G}'$ and $\|B\|^\varepsilon < \delta$.

Let $T_1 \in B_\delta(T')$, therefore $T_1 = \langle C, D \rangle$ with $C \cong T', D \in \mathcal{P} \mathcal{G}'$. As in the proof of Lemma 11.2 one dervies a SOD $T_1 = \langle A', B', D \rangle$ with $A' \cong T, B' \cong D$. From (165) we deduce the inequality $\|\langle B', D \rangle\|^\varepsilon \leq \|B'\|^\varepsilon < \delta$, which amounts to the required $T_1 \in B_\delta(T)$.

Proposition 11.7 (a) The function below is upper semi-continuous:
\[ \mathcal{P} \mathcal{G} \xrightarrow{\|\cdot\|^\varepsilon} \mathbb{R} \quad [T] \mapsto \|T\|^\varepsilon \] (166)

(b) For any $x > 0$ the subset $\mathcal{P} \mathcal{G}_{\geq x} = \{y \in \mathcal{P} \mathcal{G} : \|y\|^\varepsilon \geq x\}$ is a discrete subset of $\mathcal{P} \mathcal{G}$ w. r. to the topology from Lemma 11.6.

Proof (a) follows from the following application of (165): for any $\delta > 0, T \in \mathcal{P} \mathcal{G}'$ holds
\[ \forall [T'] \in (B_\delta(T)/\cong) \setminus \{[T]\} \quad 0 \leq \|T'\|^\varepsilon \leq \min\{\|T\|^\varepsilon, \delta\}. \] (167)

(b) follows from the same formula. Indeed, from this formula one checks that for any $[T] \in \mathcal{P} \mathcal{G}_{\geq x}$ and any $0 < \delta < x$ we have $\mathcal{P} \mathcal{G}_{\geq x} \cap (B_\delta(T)/\cong) = \{[T]\}$.

Corollary 11.8 $\mathcal{D} \mathcal{R} \cup \{[D^b(Q)] : Q \text{ is affine}\}$ is a discrete subset of $\mathcal{P} \mathcal{G}$ with respect to the topology introduced in Lemma 11.6.
Corollary 11.10  For any smooth complete rational surface surface $S$ holds

$$\mathcal{D}\mathcal{D}\mathcal{R} \cup \{[D^b(Q)]: Q \text{ is affine}\} \subset \mathfrak{P}\mathcal{S}_{\geq \pi(1-\varepsilon)}.$$  \hspace{1cm} (168)

On the other hand from Proposition 11.7(b) we know that $\mathfrak{P}\mathcal{S}_{\geq \pi(1-\varepsilon)}$ is a discrete subset and the corollary follows. $\square$

Examples of non-closed points are contained in Proposition 8.5. More precisely:

Proposition 11.9  The element $[D^b(\text{point})] \in \mathfrak{P}\mathcal{S}$ is in the closure of $[T] \in \mathfrak{P}\mathcal{S}$ for any $T \in \mathfrak{P}\mathcal{S}'$ which satisfies the conditions of Corollary 8.3 and such that $\text{rank}(K_0(T)) \geq 3$.

Proof  We will show that $[T] \in B_\delta(D^b(\text{point}))/ \cong$ for any $\delta > 0$. Indeed, take any $\delta > 0$. From (119) it follows that there exists $N$ s.t. $\pi(1-\varepsilon) - K_\varepsilon(l) < \delta$ for $l \geq N$. Since $T$ satisfies the conditions of Corollary 8.3 and $\text{rank}(K_0(T)) \geq 3$, therefore there is a full exceptional collection $E_0, E_1, \ldots, E_{n-1}, E_n$ with $n \geq 2$, s.t. $\text{hom}^{\min}(E_j, E_j) > N$ for some $i < j$. Since we can apply mutations, we can assume that $\text{hom}^{\min}(E_{n-1}, E_n) > N$. Now let us denote $A = \langle E_0, B = \langle E_1, \ldots, E_n \rangle$. Then we have a SOD $T = \langle A, B \rangle$ with $A \cong D^b(\text{point})$, and $\|B\|^e \leq \|E_{n-1}, E_n\|^e \leq \pi(1-\varepsilon) - K_\varepsilon(\text{hom}^{\min}(E_{n-1}, E_n)) < \delta$, where in the latter chain of inequalities we used (165), Proposition 8.1. Recalling the definition of $B_\delta(D^b(\text{point}))$ (Definition 11.5) we conclude that $T \in B_\delta(D^b(\text{point}))$ and the proposition follows. $\square$

Corollary 11.10  For any smooth complete rational surface surface $S$ holds $[D^b(\text{point})] \in \text{Cl}([D^b(S)])$.

12 Non-commutative curve-counting

12.1 Rescaling $\|\| \frac{1}{2}$ so that all natural numbers are values

Following Kontsevich–Rosenberg [32] we denote $D^b(K(l+1))$ by $N\mathbb{P}^l$ (non-commutative projective space) for $l \geq 0$. Note that we include the case $l = 0$, and $N\mathbb{P}^0$ is a non-trivial category. We denote also $N\mathbb{P}^{-1} = D^b(K(l+1))$, i.e. this is a category generated by an orthogonal exceptional pair. Then we define for a category with a phase gap $T$:

$$\dim_{nc}(T) = \begin{cases} 0 & \text{if } \forall \text{ full } \sigma \in \text{Stab}(T) \ |P_\sigma| < \infty \\ \frac{2}{\cos(\|T\| \frac{1}{2})} - 1 & \text{if } \|T\| \frac{1}{2} < \pi/2 \text{ and } \exists \text{ full } \sigma \in \text{Stab}(T) \text{ s.t. } |P_\sigma| = \infty \\ +\infty & \text{if } \|T\| \frac{1}{2} = \pi/2 \end{cases}$$

and using (12), and table (9) we see that

$$\dim_{nc}(N\mathbb{P}^l) = l \ l \geq 0 \ \dim_{nc}(N\mathbb{P}^{-1}) = 0.$$  \hspace{1cm} (169)
Due to Theorem 6.1 and Remark 6.2 we have
\[
\dim_{nc}(\langle A, B \rangle) \geq \max\{\dim_{nc}(A), \dim_{nc}(B)\},
\]
whenever \( A, B \) have phase gap and \( \langle A, B \rangle \) is a semi-orthogonal decomposition of a proper category. (170) ensures that whenever \( T \) has a finite \( \dim_{nc}(T) < +\infty \) and \( A \subset T \) is a good enough embedded subcategory, then \( A \) has also finite \( \dim_{nc}(A) \leq \dim_{nc}(T) < +\infty \). We note also that

**Remark 12.1** Proposition 4.19 and table (9) imply that for an acyclic quiver \( Q \) we have \( \dim_{nc}(D^b(Q)) = 0 \) iff \( Q \) is Dynkin and \( \dim_{nc}(D^b(Q)) = 1 \) iff \( Q \) is affine.

### 12.2 A question and a definition

We start with two remarks:

**Remark 12.2** Recall that the homological dimension of \( NP^l \), \( l \geq 0 \) is one. Also due to table (10) we have \( \text{Stab}(NP^l) \cong \mathbb{C} \times \mathbb{C} \) for \( l = 0, 1 \) and \( \text{Stab}(NP^l) \cong \mathbb{C} \times \mathcal{H} \) for \( l \geq 2 \). Note also that, whereas the spirals in \( NP^0 \) are periodic (up to shifts there are only three exceptional objects), for \( l \geq 1 \) the spirals in \( NP^l \) consist of pairwise non-isomorphic objects.

In view of these notes, we find it convenient to view \( NP^l \) as a non-commutative curve of genus \( l \).

Note that \( NP^{-1} \) has homological dimension 0 and one should not think of this as a curve. Nevertheless, in order that we include also \( NP^{-1} \) in the terminology we refer to it as a “non-commutative curve of genus \(-1\)” (a kind of degenerate curve).

**Remark 12.3** Let \( l \geq -1 \) and \( T \) be any triangulated category linear over \( \mathbb{K} \), let \( NP^l \xrightarrow{F} T \) be any fully faithful \( \mathbb{K} \)-linear exact functor,\(^9\) and denote by \( A \) the isomorphism closure of the image of \( F \) in \( T \). Then \( A \) is a triangulated subcategory of \( T \) generated by two exceptional objects and it is equivalent to \( NP^l \), hence due to [8, Theorem 3.2] the functor \( F \) has left and right adjoints and there are SOD \( T = \langle A, A^\perp \rangle, \quad T = \langle A^\perp, A \rangle \), in particular \( T \in B(NP^l) \) (see Definition 11.1).

Due to (170) we see that whenever we have \( T \in B_\delta(NP^l) \) for some real \( \delta > 0 \) (recall that by definition 11.5 this implies that there is a SOD of the form \( T = \langle NP^l, A \rangle \) where \( A \) has a phase gap) and some integer \( l \geq 0 \), then \( \dim_{nc}(T) \geq l \). In particular if \( T \in B_\delta(NP^l) \) for arbitrary big \( l \), then \( \dim_{nc}(T) = +\infty \), and this was used in Sect. 8. Now we come to the question of this section:

**Question 12.4** Incidences \( T \in B(NP^l) \)\(^10\) are embeddings of \( NP^l \) into \( T \). Viewing such embeddings as non-commutative curves in the category \( T \) we ask how many are these curves in a given \( T \)?

\(^9\) Recall that an exact functor is actually a a pair of a functor \( F' \) and a natural isomorphism between the functors \( F' \circ T_1 \) and \( T_2 \circ F_2 \), where \( T_1, T_2 \) are the translation functors of the source and the target categories, respectively.

\(^{10}\) i.e. a SOD \( \langle NP^l, A \rangle \).
In this section we sketch the concept of non-commutative curve-counting and give several numbers which result from this counting. The proofs and further numbers are in [20] and in future works. The first step is the following definition (see [20, Sections 3,4] for details):

**Definition 12.5** Let $\mathcal{A}$, $\mathcal{T}$ be any triangulated categories. And let $\Gamma \subset \text{Aut}(\mathcal{T})$ be a subgroup of the group of auto-equivalences. We denote

$$C'_{\mathcal{A}, p}(\mathcal{T}) = \{\mathcal{A} \xrightarrow{F} \mathcal{T} : F \text{ is fully faithful exact functor satisfying properties } P\}.$$  

(171)

Next we fix an equivalence relation in $C'_{\mathcal{A}, p}(\mathcal{T})$, and we will be interested in the set of equivalence classes, in particular the size of this set.

$$C'_{\mathcal{A}, p}(\mathcal{T}) = C'_{\mathcal{A}, p}(\mathcal{T})/\sim \quad F \sim F' \iff F \circ \alpha \cong \beta \circ F' \text{ for some } \alpha \in \text{Aut}(\mathcal{A}), \beta \in \Gamma$$  

(172)

where $F \circ \alpha \cong \beta \circ F'$ means equivalence of exact functors between triangulated categories (this is so called graded equivalence).

### 12.3 First non-trivial examples with $\mathcal{A} = N\mathbb{P}^d$, $l \geq -1$ and three different targets: two quivers, and $D^b(\mathbb{P}^2)$

Here we specify $\mathcal{A} = N\mathbb{P}^d$ in Definition 12.5 and $\mathcal{T}$ is a $\mathbb{K}$-linear category. We note first an example of a choice for the additional property $P$ in Definition 12.5:

**Remark 12.6** Let us choose the additional properties $P$ from (171) as follows:

Property $P : F$ is $\mathbb{K}$-linear, the left or the right orthogonal to $\text{Im}(F)$ in $\mathcal{T}$ has a phase gap

(173)

This paper contains examples of $\mathcal{T}$ and $l \geq 0$, s. t. $C^{\Gamma}_{N\mathbb{P}^d, p}(\mathcal{T}) \neq \emptyset$. On the other hand from (170) follows:

$$\dim_{nc}(\mathcal{T}) \leq n \implies C^{\Gamma}_{N\mathbb{P}^d, p}(\mathcal{T}) = \emptyset \text{ for } l > n.$$  

(174)

In all the examples of categories $\mathcal{T}$ with $\dim_{nc}(\mathcal{T}) = \infty$ given in Sect. 8 one has $C^{\Gamma}_{N\mathbb{P}^d, p}(\mathcal{T}) \neq \emptyset$ for infinitely many $l$.

Next we note examples, where the additional restriction $P$ from Remark 12.6 is equivalent to requiring only $\mathbb{K}$-linearity:

**Remark 12.7** When $\mathcal{T} = D^b(\mathbb{P}^2)$ or $\mathcal{T} = D^b(Q)$ for an acyclic quiver $Q$, then for any fully faithful exact $\mathbb{K}$-linear functor $F : N\mathbb{P}^d \to \mathcal{T}$ the right and the left orthogonal to the image of $F$ is generated by an exceptional collection, therefore any such functor automatically satisfies the additional property $P$ in 173. This follows from the fact
that every exceptional pair in $\mathcal{T}$ can be extended to a full exceptional collection in $\mathcal{T}$ (this is proved in [17] and [26]).

So, let us specify Definition 12.5 with this simpler $P$, that is (see [20, Section 5] for detailed exposition):

**Definition 12.8** Let $l \in \mathbb{Z}_{\geq -1}$ and let $\mathcal{T}$ be any $\mathbb{K}$-linear triangulated category. And let $\Gamma \subset \text{Aut}_\mathbb{K}(\mathcal{T})$ (where $\text{Aut}_\mathbb{K}(\mathcal{T})$ is the group of $\mathbb{K}$-linear auto-equivalences). Let the property $P$ from Definition 12.5 be "$F$ is $\mathbb{K}$-linear". We denote $\mathcal{C}_{\Gamma}^{l}(\mathcal{T})$ by $\mathcal{C}_{\Gamma}^{l}(\mathcal{T})$ and refer to the elements of $\mathcal{C}_{\Gamma}^{l}(\mathcal{T})$ as to non-commutative curves of genus $l$ in $\mathcal{T}$ modulo $\Gamma$.

The invariants just defined are computed for two affine quivers in [20, Section 6], the result is:

**Proposition 12.9** Let $\mathcal{T}_i = D^b(Q_i)$, $i = 1, 2$, where: $Q_1$, $Q_2$

$$Q_1 = \begin{array}{ccc} 1 & 2 & 3 \\ \downarrow & \downarrow & \downarrow \\ 2 & 3 & 1 \end{array}$$

$$Q_2 = \begin{array}{ccc} 1 & 4 & 3 \\ \uparrow & \uparrow & \uparrow \\ 2 & 1 & 4 \end{array}$$

Then the numbers $|\mathcal{C}_{\Gamma}^{l}(\mathcal{T}_i)|$ for $l \in \{-1, 0, +1\}$, $i = 1, 2$, $\Gamma \in \{\text{Id}, (S)\}$, $\text{Aut}_\mathbb{K}(\mathcal{T}_i)$

are:

$$|\mathcal{C}_{\Gamma}^{l}(\mathcal{T}_1)| = \begin{array}{cccc} \Gamma & \{\text{Id}\} & (S) & \text{Aut}_\mathbb{K}(\mathcal{T}_1) \\ -1 & 0 & 0 & 0 \\ 0 & \infty & 3 & 1 \\ +1 & 2 & 1 & 1 \end{array}$$

$$|\mathcal{C}_{\Gamma}^{l}(\mathcal{T}_2)| = \begin{array}{cccc} \Gamma & \{\text{Id}\} & (S) & \text{Aut}_\mathbb{K}(\mathcal{T}_2) \\ -1 & \infty & 4 & 2 \\ 0 & \infty & 8 & 1 \\ +1 & 4 & 2 & 1 \end{array}$$

$$l \geq 2 \Rightarrow |\mathcal{C}_{\Gamma}^{l}(\mathcal{T}_1)| = |\mathcal{C}_{\Gamma}^{l}(\mathcal{T}_2)| = 0,$$

**Proof** The vanishings follow from (8). The rest of the proof is in [20].

In [20] we estimate the new invariants defined in Definition 12.8, the result is as follows:

**Proposition 12.10** Let $\mathbb{K} = \mathbb{C}$. Denote $\mathcal{T} = D^b(\mathbb{P}^2)$. Let $(S) \subset \text{Aut}_\mathbb{C}(\mathcal{T})$ be the subgroup generated by the Serre functor. Then $C_{-1}^{(S)}(\mathcal{T}) = \emptyset$ and $\forall l \geq 0$ the set $C_{l}^{(S)}(\mathcal{T})$ is finite. It is non-empty for:

$$\left\{ l \geq 0 : C_{l}^{(S)}(\mathcal{T}) \neq \emptyset \right\} = \left\{ l \geq 0 : C_{l}^{(S)}(\mathcal{T}) \neq \emptyset \right\} = \{3m - 1 : m \text{ is a Markov number}\}. \quad (175)$$

Furthermore, for any Markov number\(^{11}\) $m$ we have

$$|C_{3m-1}^{(S)}(\mathcal{T})| = \infty \quad (176)$$

\(^{11}\) Recall that a Markov number $x$ is a number $x \in \mathbb{N}_{\geq 1}$ such that there exist integers $y, z$ with $x^2 + y^2 + z^2 = 3xyz$.
Some new categorical invariants

$1 \leq \left| C^\text{Aut}_c(T)_{3m-1}(T) \right| \leq m,$

$(177)$

$3 \leq \left| C^\text{(S)}_{3m-1}(T) \right| = 3 \left| C^\text{Aut}_c(T)_{3m-1}(T) \right| \leq 3m,$

$(178)$

where $c_1(E), r(E)$ are the first Chern class (which we consider as an integer) and the rank of $E$.

**Proof** See [20, Section 8].

**Corollary 12.11** Denote $T = D^b(P^2)$. The first several non-trivial $\left| C^\text{Aut}_c(T)_{3m-1}(T) \right|$ are (recall that $m$ is a Markov number and on the first row are listed the first 9 Markov numbers):

\[
\begin{array}{c|cccccccc}
 & m & 1 & 2 & 5 & 13 & 29 & 34 & 89 & 169 & 194 \\
\hline
\left| C^\text{Aut}_c(T)_{3m-1}(T) \right| & 1 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2
\end{array}
\]

$(179)$

Furthermore, the so called Tyurin’s conjecture, which is equivalent to the Markov’s conjecture (this equivalence is proved in [36, p. 100], see also [25, Section 7.2.3 ] is equivalent to the following statement: for all Markov numbers $m \neq 1, m \neq 2$ we have $\left| C^\text{Aut}_c(T)_{3m-1}(T) \right| = 2$.

**Proof** See [20, Section 8].

**12.4 Dependence on a stability condition: semistable, resp. stable. non-commutative curves**

**Definition 12.12** Let $l \in \mathbb{Z}_{\geq -1}$ and let $T$ be a triangulated category linear over $\mathbb{K}$ and s.t. $\text{Stab}(T) \neq \emptyset$, let $\Gamma$ and $P$ be as in Definition 12.5. One approach to define, semi-stable w.r. to a stability condition non-commutative curves in $T$ is as follows. Choose $\sigma \in \text{Stab}(T)$. Now we apply the same Definition 12.5 with $A = N \mathbb{P}^l$ and $P$ is the one from Definition 12.8 twisted by an additional restriction depending on $\sigma$. We give two options for this additional restriction. More precisely, let $\{s_j\}_{j \in \mathbb{Z}}$ be a Helix in $N \mathbb{P}^l$ (see [20, Section 7.2]), then let us denote:

\[
C'_{l,\sigma}(T) = \left\{ F \in C'_{N \mathbb{P}^l,\mathbb{K}}(T) : \left| \{ j : F(s_j) \in \sigma^{\text{ss}} \} \right| = \infty \right\}
\]

$(180)$

\[
C'_{l,\sigma\sigma}(T) = \left\{ F \in C'_{l}(T) : \forall j \in \mathbb{Z}, F(s_j) \in \sigma^{\text{ss}} \right\}
\]

$(181)$

where $C'_{N \mathbb{P}^l,\mathbb{K}}$ is the set (171) (see also Definition 12.8) and $\sigma^{\text{ss}}$ is the set of $\sigma$-semistable objects. The formulas (172) give equivalence relations in $C'_{l,\sigma}(T)$ and in $C'_{l,\sigma\sigma}(T)$ and we define $\sigma$-semistable (resp. $\sigma$-stable) non-commutative curves of genus $l$ in $T$, and modulo $\Gamma$:

\[
C^\Gamma_{l,\sigma}(T) = C'_{l,\sigma}(T) / \cong \quad C^\Gamma_{l,\sigma\sigma}(T) = C'_{l,\sigma\sigma}(T) / \cong
\]
Note that for \( l = 0, l = -1 \) we have always \( C_{1,l}^\Gamma(T) = \emptyset \).

We will give two examples. In both of them \( \Gamma = \{\text{Id}\} \). Here we prove only one of them. To that end we note first a lemma

**Proposition 12.13** Let \( l \geq 1 \). Then \( |C_{1,l}^{\{\text{Id}\}}(N\mathbb{P}^l)| = \delta_{k,l} \). Let \( Z \subset \text{Stab}(N\mathbb{P}^l) \) be as in Proposition 7.2. Then we have \( |C_{1,l}^{\{\text{Id}\}}(N\mathbb{P}^l)| = 1 \) for \( \sigma \in \text{Cl}(Z) \) and \( |C_{1,l}^{\{\text{Id}\}}(N\mathbb{P}^l)| = 0 \) for \( \sigma \notin \text{Cl}(Z) \).

**Proof** From the Remark 12.3 it follows that, if for some integer \( j \geq -1 \) there exists a fully faithful \( \mathbb{K} \)-linear functor \( N\mathbb{P}^j \xrightarrow{F} N\mathbb{P}^l \), then \( l = j \) and \( F \) is equivalence (from [17] we know that any exceptional pair in \( N\mathbb{P}^l \) is full). It follows the equality \( |C_{1,l}^{\{\text{Id}\}}(N\mathbb{P}^l)| = \delta_{k,l} \). For the proof of the rest we note first that for any \( j \) the subset in \( \text{Stab}(N\mathbb{P}^l) \) where \( s_j \) is semi-stable is closed subset. From Proposition 7.2 we know that for \( \sigma \in Z \) all elements in \( \{s_j\}_{j \in \mathbb{Z}} \) are semi-stable, therefore this holds also for \( \sigma \in (Z) \). Thus we see that \( \sigma \in \text{Cl}(Z) \Rightarrow |C_{1,l\sigma}(N\mathbb{P}^l)| = 1 \).

Now let \( \sigma \notin \text{Cl}(Z) \). We will show that \( |C_{1,l\sigma}(N\mathbb{P}^l)| = 0 \) and the Proposition follows. Indeed recalling also that in Proposition 7.2 we have also disjoint union \( \text{Stab}(N\mathbb{P}^l) = Z \cup \bigcup_{i \in \mathbb{Z}} Z_i \) and (78) we deduce that for some \( i \in \mathbb{Z} \) we have \( s_i, s_{i+1} \in \sigma^s \), \( 1 \leq \phi(s_{i+1}) - \phi(s_{i+1}) \). Now if \( 1 = \phi(s_{i+1}) - \phi(s_{i+1}) \), then using (79) this would imply that \( \sigma \in \text{Cl}(Z) \), therefore \( 1 < \phi(s_{i+1}) - \phi(s_{i+1}) \). In this case the last statement in Proposition 7.2 ensures that only \( s_i, s_{i+1} \) are semi-stable, therefore \( |C_{1,l\sigma}(N\mathbb{P}^l)| = 0 \).

In the master thesis [6] is proved:

**Proposition 12.14** Let \( T = D^b(Q_1) \) (\( Q_1 \) is as in Proposition 12.9). As \( \sigma \) varies in \( \text{Stab}(T) \) the subset \( C_{1,l\sigma}(T) \subset C_{1,l}^{\{\text{Id}\}}(T) \) takes all possible subsets of \( C_{1,l}^{\{\text{Id}\}}(T) \).

**Remark 12.15** We expect that Proposition 12.14 holds for \( C_{1,l\sigma}(T) \) as well.

### 12.5 Non-commutative Calabi–Yau curve-counting

Now we sketch a conjectural example of a finite \( C_{A,\rho}^\Gamma(T) \) (defined in Definition 12.5) coming from categories appearing naturally on the A-side. Here the categories are \( \mathbb{C} \)-linear and we fix the property \( P \) of the functor \( F \) in Definition 12.5 to be “\( F \) is \( \mathbb{C} \)-linear” and we will write \( C_{A,\rho}^\Gamma(T) \) instead of \( C_{A,\rho}^\Gamma(T) \). Now the domain category \( A \) is a modification of \( D^b(K(l)) \), which is Calabi–Yau. We pass from \( D^b(K(l)) \) to the new domain by changing

\[
\begin{align*}
\{\text{exceptional objects}\} & \quad \longleftrightarrow \quad \{\text{spherical objects}\}
\end{align*}
\]

and this amounts to considering \( A = CY(l) \), instead of \( A = D^b(K(l)) \). The definition is based on the quiver:
In the next conjectural example $\Gamma = \text{Aut}_\mathbb{C}(T)$ is the group of $\mathbb{C}$-linear auto-equivalences of $T$:

**Conjecture 12.16** Let $T = \text{Fuk}(E)$ with $E$ an elliptic curve. In this case we have a correspondence:

$$C_{\text{Aut}_\mathbb{C}(T)}^{\text{CY}(n), \mathbb{C}}(T) \leftrightarrow \left\{ \begin{array}{c} \text{Primitive Lagrangian} \\ \text{generating } \text{Fuk}(E) \end{array} \right\}$$

It follows that: $\left| C_{\text{Aut}_\mathbb{C}(T)}^{\text{CY}(n), \mathbb{C}}(T) \right| = \# \{ d \mid \gcd(d, n) = 1, 1 \leq d \leq n \}$. We plan to work on Conjecture 12.16 in a future work.

**Remark 12.17** For curves $S$ of higher genus we expect that finding of the cardinality of $C_{\text{Aut}_\mathbb{C}(T)}^{\text{CY}(n), \mathbb{C}}(T)$ for $T = \text{Fuk}(S)$ is related to very recent insights on counting of geodesics—see [33].

### 13 A-side interpretation and holomorphic sheaves of categories

In this section we give a different point of view on the category of representations of the Kronecker quiver and introduce the notion of holomorphic families of Kronecker quivers.

We suggest a framework in which sequences of holomorphic families of categories are viewed as sequences of extensions of non-commutative manifolds by relating our norm to the notion of holomorphic family of categories introduces by Kontsevich. Several questions and conjectures are posed.

First we sketch how to interpret $\text{Db}(\text{K}(n))$ as a perverse sheaf of categories. Recall that LG model of $\mathbb{P}^2$ is $\mathbb{C}^* \times \mathbb{P}^1$, $w = x + y + \frac{1}{xy}$—see [1].

The category $\text{Db}(\text{K}(3))$ can be obtained by taking the part of the Landau Ginzburg model over a disc $D$ which contains 2 singular fibers.

Surgeries on the manifold:

$$S^1 \times E$$
can be performed so that the Floer homology \( \text{HF}(L_1, L_2) = 3 \) changes to \( \text{HF}(L_1, L_2) = n \) and as a result we get \( D^b(K(n)) \).

To interpret \( D^b(K(n)) \) as a perverse sheaf of categories one considers a locally constant sheaf of categories over a graph \( \Gamma \) shown on the picture below, the picture encodes also the data about the sheaf:

\[
\begin{array}{c}
\mathcal{F} \\
\begin{array}{c}
P_1 \\
D^b(A_1) \\
\rightarrow \\
\downarrow \\
Fuk(E) \\
\end{array} \\
\begin{array}{c}
P_2 \\
\downarrow \\
D^b(A_2) \otimes Fuk(E) \\
\end{array} \\
\begin{array}{c}
\downarrow \\
D^b(A_1) \\
\end{array} \\
\Gamma
\end{array}
\]

The locally constant sheaf is denoted by \( \mathcal{F} \). The stalks over inner points of the edges of \( \Gamma \) are isomorphic to \( Fuk(E) \), the stalk over the vertex where three edges meet is \( D^b(A_2) \otimes Fuk(E) \), the stalks over the two end points of \( \Gamma \) on the left is \( D^b(A_1) \) (these points correspond to the two singular points of the LG model). There are three functors from \( D^b(A_2) \otimes Fuk(E) \) to \( Fuk(E) \) coming from three functors from \( D^b(A_2) \) to \( D^b(A_1) \). The letters \( p_1, p_2 \) from the figure above denote two spherical functors from \( D^b(A_1) \) to \( Fuk(E) \), thus this figure encodes a diagram of functors. One defines the category of global sections \( H^0(\Gamma, \mathcal{F}) \) of the sheaf \( \mathcal{F} \) as a category which is obtained by a limit of the described diagram of functors. For appropriately chosen spherical functors the category \( H^0(\Gamma, \mathcal{F}) \) is the same as \( D^b(K(n)) \). The surgeries are recorded by the changes of the spherical functors \( p_1, p_2 \). What we explained about interpreting \( D^b(K(n)) \) as a perverse sheaf of categories is only a sketch. More details are given in a subsequent work of the second author with Pandit and Spaide [31, Example 3.22]. In [31, page 41] are discussed also the surgeries.

The category \( D^b(K(4)) \) can be interpreted also as part of the LG model of \( \mathbb{P}^3, \mathbb{C}^* \), \( w = x + y + z + \frac{1}{xyz} \):

\[
\begin{array}{c}
K3 \\
\begin{array}{c}
\cdot \\
\cdot \\
\cdot \\
\cdot \\
\end{array} \\
D \\
\cdot \\
\cdot \\
\cdot \\
\end{array}
\]

\[
\begin{array}{c}
D^b(K(4)) \\
\begin{array}{c}
\cdot \\
\cdot \\
\end{array} \\
K3 \\
\cdot \\
\cdot \\
\end{array}
\]

In this case surgeries on the fiber - a \( K3 \) surface:
can be performed so that the category changes from $\text{Db}(K(4))$ to $\text{Db}(K(n))$.

The Landau Ginzburg models with $K3$ surfaces in the fibers can be interpreted as perverse sheaves of categories, encoded in the following picture—see [27]:

\[
\begin{array}{c}
\text{F}
\end{array}
\]

Remark 13.1 The property of having a phase gap, which we require in this paper to define the norm, can also be interpret as existence of a CY form with certain properties. Namely let $Y$ be a LG model, $\Omega$ is a CY form on $Y$. Let $L$ be a Lagrangian s.t. $\theta_1 \leq \arg\Omega|_L \leq \theta_2$. Assume that there exits a form $\beta$ on $Y$ s.t. (1) $\beta = d\alpha$, ($\alpha$ is an $n-1$ form), (2) $\text{Re}\beta|_L > 0$, (3) $\alpha \to 0$ when $\omega \to 0$.

Then there are no stable lagrangians $L$ with $\theta_1 \leq \arg\Omega|_L \leq \theta_2$. In other words existence of such forms $\Omega$ and $\alpha$ lead to gaps in phases.

One more direction for future research is holomorphic families of categories, in particular holomorphic families of Kronecker quivers.

Holomorphic families of categories over $X$ with fiber $K(n)$ should be defined by homomorphisms $\varphi_i : \mathcal{O}(U_i) \to \mathcal{H}^0(\text{Db}(K(n)))$ in the zero-th Hochschild cohomology of $\text{Db}(K(n))$ where $\{U_i\}$ is a covering of $X$ by open sets. We use the following picture for such a holomorphic family of categories:

\[
\begin{array}{c}
K(n) \\
\downarrow
\end{array}
\]

The holomorphic sheaves of categories are enhanced by perverse sheaves of stability conditions - see [30] for defining morphisms and the gluing between the categories on intersecting opens that defines the sheaf.

The case of holomorphic family of $K(2)$ is the classical case of conic bundles:

\[
\begin{array}{c}
Z \text{ conic} \\
\downarrow
\end{array}
\]

The global sections $H^0(X, \mathcal{F})$ are $\text{Db}(Z)$. Similarly $H^0(X, \mathcal{F})$ with $K(n)$ for $n \geq 3$ produces a new non-commutative variety.

Iterating the procedure described above results in a family of categories over a family of categories. Some questions addressing relations between the norms of the fibers and of the gobal sections follow:
Question 13.2 Under what condition $\|\mathcal{C}\|_\varepsilon \geq \|H^0(X, \mathcal{F})\|_\varepsilon$? (here $\mathcal{C}$ is the category in the fiber)

$\mathcal{C} \downarrow \mathcal{F} \quad \downarrow \quad X$

Question 13.3 Let us consider a tower of families of categories and each of the fiber categories $\mathcal{C}_i$ has non maximal $\|\cdot\|_\varepsilon$ (recall the relation of $\|\cdot\|_\varepsilon$ and $\|\cdot\|_\varepsilon$ in Definition 11.5). Is it true that if the Rouquier dimension [2] of the category in the combined fiber is one then the norm $\|\cdot\|_\varepsilon$ of this category is non-maximal?

We summarise the proposed analogy in the table below.

| Galois theory | Norms |
|---------------|-------|
| $X_2$ finite $X_2$ $\downarrow$ | $\mathcal{C}_2$ $\|\mathcal{C}_2\|_\varepsilon < \max$ $\downarrow$ |
| $X_1$ finite $X_1$ | $\mathcal{C}_1$ $\|\mathcal{C}_1\|_\varepsilon < \max$ |
| $X$ | $\mathcal{C}$ $\downarrow$ $X$ |

The sequence of finite coverings is finite

Rouquier dim $(\mathcal{C}) = 1$

$\|\cdot\|_\varepsilon < \max$

Question 13.4 Do we have a similar theory as the classical theory of conic bundles for sheaves of categories with fibers categories of representations of Kronecker quivers or any other quiver category with a Rouquier dimension [2] equal to one?

In a certain way our norm can be seen as analogue of height function defined in [15]. We expect that some higher analogues of this norm for higher Rouquier dimensions can be defined. In fact in this paper we only scratch the surface proposing a possible approach to “noncommutative Galois theory”—representing “noncommutative manifolds” (categories) as a sequence of perverse sheaves of categories and holomorphic families of categories.

It will be interesting to study categories which can be represented as a tower of holomorphic families of categories with nonmaximal norms $\|\cdot\|_\varepsilon$. One example of such category is $D^b(\mathbb{P}^1 \times \cdots \times \mathbb{P}^1)$.

Question 13.5 Characterise projective varieties $X$ whose derived categories $D^b(X)$ can be represented as tower of holomorphic families of categories with non-maximal norms starting with $D^b(Z)$, whehre $Z$ is a rational variety.
(1) Under what conditions are these projective varieties $X$ rational? (It is rather clear that a nontrivial condition is needed since every hyperelliptic curve can be seen as such a tower).

(2) We conjecture that for a unirational variety $U$ there is a tower of families of categories

$$D^b(Z) \xrightarrow{F_1} Z_1 \xrightarrow{F_2} Z_2 \cdots \rightarrow D^b(U)$$

and each of the fiber categories has non-maximal norm: $\|F_i\|_\epsilon < \pi (1 - \epsilon)$ (see [5]), and $Z$ is rational.

Acknowledgements Open access funding provided by University of Vienna. The authors wish to express their gratitude to Dhyan Aranha, Aleksej Bondal, Bogdan Georgiev and Maxim Kontsevich for their interest. The authors are very thankful to Denis Auroux for his help on the last Sect. 13. The first author was supported by FWF Projects P 29178-N35, P 27784. Parts of this work was carried out during the stay 01.07.15-30.06.16 of the first author at the Max-Planck-Institute für Mathematik Bonn and his stay 01.07.16-30.06.17 at International Centre for Theoretical Physics Trieste and G. Dimitrov gratefully acknowledges the support and the excellent conditions at these institutes. The second author was supported by Simons research Grant, NSF DMS 150908, ERC Gemis, DMS-1265230, DMS-1201475 OISE-1242272 PASI. Simons collaborative Grant-HMS. HSF-Grant, HMS and automorphic forms. The second author is partially supported by Laboratory of Mirror Symmetry NRU HSE, RF Government Grant, ag. No 14.641.31.0001. Connection with our preprint arXiv:1602.09117: Following advice by Auroux, Panjet, Kontsevich and one referee we split the paper arXiv:1602.09117 into two parts. The present paper is the second part.
