The thermal conductivity of suspended single-layer graphene was measured as a function of temperature using Raman scattering spectroscopy on clean samples prepared directly on a prepatterned substrate by mechanical exfoliation without chemical treatments. The temperature at the laser spot was monitored by the frequency of the Raman 2D band of the Raman scattering spectrum, and the thermal conductivity was deduced by analyzing heat diffusion equations assuming that the substrate is a heat sink at ambient temperature. The obtained thermal conductivity values range from \(\sim 1800 \text{ Wm}^{-1}\text{K}^{-1}\) near 325 K to \(\sim 710 \text{ Wm}^{-1}\text{K}^{-1}\) at 500 K.

I. INTRODUCTION

Graphene is attracting much interest not only owing to its novel physical properties,1–3 but also because of possible applications as a candidate material to replace silicon in future electronic devices.4–6 In addition to its high charge carrier mobility,7,8 its superior thermal properties are considered to be crucial in high-density large-scale integrated circuits where heat management is becoming more important as the density of devices grows.2 Balandin et al. first reported extremely large values for the thermal conductivity (\(\kappa\)) in the range of 4840\(\pm\)440 to 5300\(\pm\)480 Wm\(^{-1}\)K\(^{-1}\) for mechanically exfoliated single-layer graphene near room temperature.10 These values are among the largest ever measured from any material so far.

Several groups since have measured \(\kappa\) of mechanically exfoliated10–12 or chemical vapor deposition (CVD)-grown13,14 graphene samples using different methods. For suspended, exfoliated single-layer graphene, Faugeras et al. reported a value of \(\sim 630 \text{ Wm}^{-1}\text{K}^{-1}\) at 660 K11 much lower than those of Balandin et al.10 On CVD-grown graphene, Ruoff’s group13,14 reported \(\kappa\) values ranging from \((2500 + 1100/− 1050) \text{ Wm}^{-1}\text{K}^{-1}\) to \((2600\pm900 to 3100\pm1000) \text{ Wm}^{-1}\text{K}^{-1}\) at 350 K. Since \(\kappa\) is in principle a function of temperature and the measured values may be affected by the residual chemicals left on the samples as a result of the sample preparation processes, direct comparison of these later values with those of Balandin et al. has been difficult. Given the importance of this key parameter for device applications, an accurate measurement and critical comparison with previous measurements are crucial. Here, we present the measurement of \(\kappa\) for suspended single-layer graphene at temperatures between 300 K and 500 K using Raman scattering spectroscopy on a clean sample prepared directly on a prepatterned substrate without involving a transfer process.

II. EXPERIMENTAL

The substrates with round holes with various diameters were prepared by photolithography and dry etching of Si substrates covered with a 300 nm-thick SiO\(_2\)

layer. The depth of the holes is \( \sim 1.7 \, \mu \text{m} \), deep enough to prevent interference from laser light reflected and scattered from the bottom of the holes. The diameters were 2.6, 3.6, 4.6, and 6.6 \( \mu \text{m} \). The graphene samples were prepared directly on the cleaned substrate by mechanical exfoliation from natural graphite flakes. No chemical treatment of the sample was involved in the preparation process. This ensures that the sample surface is free from chemical contaminants that may affect the measured \( \kappa \) values. The sample used was a single-layer graphene flake of 35\( \times \)60 \( \mu \text{m}^2 \) dimensions identified by the line shape of the 2D band in the Raman spectrum. The 514.5-nm (2.41 eV) beam of an Ar ion laser was focused through suspended graphene and supported graphene on the substrate as well as between graphene and the substrate, in addition to the purely thermal effect. Since graphene samples suspended over a trench or a hole is less affected by the strain due to the thermal expansion coefficient difference, we used the values reported recently by Chen et al. on suspended graphene samples. They measured the temperature coefficients of the G and 2D bands and found that the 2D band \( (\partial \omega_{2D}/\partial T = -0.072 \pm 0.002 \text{cm}^{-1} \text{K}^{-1}) \) is more sensitive to temperature than the G band \( (\partial \omega_{G}/\partial T = -0.044 \pm 0.003 \text{cm}^{-1} \text{K}^{-1}) \). Therefore, we used the 2D band for the estimate of the temperature in this work.

Figure 2 summarizes the shift of the 2D band as a function of the incident laser power. As the laser power increases, the 2D band redshifts due to increased heating. For smaller holes, the shift is smaller because efficient heat conduction to the substrate limits the temperature rise at the laser spot. It should be noted that the largest hole (6.6 \( \mu \text{m} \)) shows a smaller shift than the 4.6-\( \mu \text{m} \) hole. This trend was confirmed by repeated measurements on several holes. This may be explained in the following way. As the hole size increases, the laser spot moves away from the edge of the hole, reducing the heat conduction to the substrate, and the temperature should increase. Beyond a certain hole size, the temperature would saturate if one ignores the thermal conduction to the ambient air. In reality, the conduction to air, however small, would decrease the temperature for larger holes, resulting in a smaller temperature rise for the larger holes.

In order to estimate the thermal conductivity, we used the heat diffusion equation ignoring the heat conduction to the ambient air. We considered heat conduction through suspended graphene and supported graphene on the substrate as well as between graphene and the substrate. The substrate is assumed to be a heat sink at the ambient temperature. With cylindrical symmetry, one can write the heat diffusion equation as:

\[
\kappa \frac{1}{r} \frac{d}{dr} \left( r \frac{dT(r)}{dr} \right) + q(r) = 0 \quad \text{for} \quad r < R, \tag{1}
\]

where \( R \) is the radius of the hole, \( r \) is the radial position, and \( \kappa \) is the thermal conductivity of suspended graphene. \( q(r) = (1/\kappa)(t/\alpha) \exp(-2r^2/w^2) \) is the heat inflow per unit volume due to laser excitation, where \( I \) is the laser intensity, \( \alpha \) is the absorptance of light in single layer graphene (2.3\%) and \( t \) is the thickness of graphene (0.335 nm). Outside the hole, where graphene is sup-

Bessel functions, and

\( r \gamma \) is the interfacial thermal conductance between graphene and SiO\(_2\) (100 MWm\(^{-2}\)K\(^{-1}\)). The general solutions to Eqs. (1) and (2) are

\[
T_1(r) = c_1 + c_2 \ln(r) + c_3 E\!i\left(\frac{-y^2}{r_0}\right) \quad \text{for} \quad r < R, \\
T_2(\gamma) = c_4 I_0(\gamma) + c_5 K_0(\gamma) + T_a \quad \text{for} \quad r \geq R,
\]

where \( c_i \)'s are arbitrary constants, \( E\!i(x) \) is an exponential integral, \( I_0(x) \) and \( K_0(x) \) are the zero-order modified Bessel functions, and \( \gamma = r(\sigma_i/(\kappa' R))^\frac{1}{2} \). For a converging solution, \( c_4 = 0 \). The boundary conditions are:

\[
T_2(r \to \infty) = T_a, \\
T_1(R) = T_2(\gamma)|_{r=R}, \\
-\kappa \frac{dT_1(r)}{dr}|_{r=R} = -\kappa' \frac{dT_2(\gamma)}{dr}|_{r=R}, \\
-2\pi R \kappa' \frac{dT_2(\gamma)}{dr}|_{r=R} = Q,
\]

where \( Q \) is the total laser power absorbed. The coefficients \( c_i \)'s of Eqs. (3) and (4) are determined from these boundary conditions. On the other hand, the measured temperature (\( T_m \)) is an weighted average of temperature inside the beam spot and can be approximated as

\[
T_m \approx \frac{\int_0^W T_1(r)q(r)rdr}{\int_0^W q(r)rdr}.
\]

By comparing the measured \( T_m \) with Eq. (9), one can determine the thermal conductivity \( \kappa \). Figure 3 shows thus determined \( \kappa \) as a function of the measured temperature. The error bars are quite large for lower temperatures because \( \Delta \omega_{2D} \), which determines \( T_m \), is quite small in comparison to the measurement resolution. Therefore, the \( \kappa \) values at temperatures below 325 K are not very reliable. It seems that \( \kappa \) decreases as the temperature increases: from \(~1800 \text{ Wm}^{-1}\text{K}^{-1} \) to \(~350 \text{ K} \) to \(~710 \text{ Wm}^{-1}\text{K}^{-1} \) near 500 K.

Our thermal conductivity values are somewhat lower than those reported for CVD graphene.\(^{23,24} \) In that work, the measured \( \kappa \) is 2600 – 3100 Wm\(^{-1}\)K\(^{-1} \) near 350 K. The major difference in that work is that they measured the transmittance (\( I_i/I_0 \)) of the graphene sample and took \( 1 - I_i/I_0 \) as the absorptance. Their value was 3.4%, which is 50% larger than the recently determined value of 2.3%\(^{23,24} \). Reflection and scattering of light on the sample surface and/or other loss of the transmitted light may account for the difference. If we use the absorptance of 3.4%, we obtain a \( \kappa \) value of \(~2700 \text{ Wm}^{-1}\text{K}^{-1} \) at ~325 K, similar to the value for CVD-grown graphene. On the other hand, Faugeras et al. reported \( \kappa \) of \(~630 \text{ Wm}^{-1}\text{K}^{-1} \) at \(~660 \text{ K} \) for exfoliated graphene,\(^{20} \) which is rather close to our result at 500 K. Another source of uncertainty in the analysis is the temperature coefficient of the Raman 2D band. A 20% variation in the temperature coefficient value would result in a similar variation in the obtained \( \kappa \) value.

In light of the above analysis, the initially reported

| Sample type          | Temp. determination | Shape   | \( \kappa \) (Wm\(^{-1}\)K\(^{-1} \)) | \( T \)  | Ref.       |
|----------------------|---------------------|---------|----------------------------------|--------|-----------|
| Exfoliated, pristine | 2D band             | Circular| \(~1800 \)                      | \(~325 \text{ K} \) | This work |
| Exfoliated, pristine | G band              | Trench  | \(~4840–5300 \)                  | RT     | Balandin et al.\(^{20} \) |
| Exfoliated, transferred | Stokes/anti-Stokes | Circular| \(~630 \)                      | \(~660 \text{ K} \) | Faugeras et al.\(^{23,24} \) |
| CVD, transferred     | G band              | Circular| \(~2500 \)                      | \(~350 \text{ K} \) | Cai et al.\(^{11} \) |
| CVD, transferred     | 2D band             | Circular| \(~2600–3100 \)                 | \(~350 \text{ K} \) | Chen et al.\(^{14} \) |
value of 5300 Wm$^{-1}$K$^{-1}$ by Balandin et al. seems to be significantly overestimated. The most significant difference between their analysis and those of recent publications including our work is the value of the absorbance $\alpha$ of single layer graphene. They used $\alpha = 13\%$, which is several times larger than the value of 2.3% accurately measured and theoretically analyzed by Nair et al. If one uses $\alpha = 2.3\%$, their $\kappa$ value would reduce to $\sim 940$ Wm$^{-1}$K$^{-1}$.

IV. CONCLUSIONS

The thermal conductivity of suspended single-layer graphene was measured as a function of temperature using Raman spectroscopy on pristine graphene samples prepared directly on a patterned substrate by mechanical exfoliation. By monitoring the temperature at the laser spot using the Raman 2D band, the thermal conductivity was deduced by analyzing heat diffusion equations. The obtained thermal conductivity values range from $\sim 1800$ Wm$^{-1}$K$^{-1}$ near 325 K to $\sim 710$ Wm$^{-1}$K$^{-1}$ near 500 K. Based on our result as well as other recent reports\textsuperscript{11,14} the initially reported\textsuperscript{10} value of 5300 Wm$^{-1}$K$^{-1}$ seems to be significantly overestimated.
