We present a proof of concept for a spectrally selective thermal mid-IR source based on nanopatterned graphene (NPG) with a typical mobility of CVD-grown graphene (up to 3000 cm²/V·s), ensuring scalability to large areas. For that, we solve the electrostatic problem of a conducting hyperboloid with an elliptical wormhole in the presence of an in-plane electric field. The localized surface plasmons (LSPs) on the NPG sheet allow for the control and tuning of the thermal emission spectrum in the wavelength regime from λ = 3 μm to 12 μm by adjusting the size of and distance between the circular holes in a hexagonal or square lattice structure. Most importantly, the LSPs along with an optical cavity increase the emittance of graphene from about 2.3% for pristine graphene to 80% for NPG, thereby outperforming state-of-the-art pristine graphene light sources operating in the near-infrared (NIR) by at least a factor of 100. According to our COMSOL calculations, a maximum emission power per area of 11 × 10³ W/m² at T = 2000 K for a bias voltage of V = 23 V is achieved by controlling the temperature of the hot electrons through the Joule heating. By generalizing Planck’s theory and considering the nonlocal fluctuation-dissipation theorem with nonlocal response of surface plasmons in graphene in the random phase approximation (RPA), we show that the coherence length of the graphene plasmons and the thermally emitted photons can be as large as 13 μm and 150 μm, respectively, providing the opportunity to create phased arrays made of nanoantennas represented by the holes in NPG. The spatial phase variation of the coherence allows for beamsteering of the thermal emission in the range between 12° and 80° by tuning the Fermi energy between ε_F = -1.0 eV and ε_F = -0.25 eV through the gate voltage. Our analysis of the nonlocal hydrodynamic response leads to the conjecture that the diffusion length and viscosity in graphene are frequency-dependent. Using finite-difference time domain (FDTD) calculations, coupled mode theory, and RPA, we develop the model of a mid-IR light source based on NPG, which will pave the way to graphene-based optical mid-IR communication, mid-IR color displays, mid-IR spectroscopy, and virus detection.

KEYWORDS: Localized surface plasmons, graphene, emissivity, grey-body thermal emission, Planck’s law, Stefan-Boltzmann law.

An object that is kept in equilibrium at a given temperature T > 0 K emits electromagnetic (EM) radiation because the charge carriers on the atomic and molecular scale oscillate due to their heat energy[2] Planck’s law describes quantitatively the energy density u(ω) of the EM radiation per unit frequency ω for black-body radiation, which is u_BB(ω)dω = 4πℏω 2θω(ω)dω, where c is the speed of light in vacuum, ℏ is the Planck constant, and k_B is the Boltzmann constant. θ(ω, T) = hω/[exp(hω/k_BT) - 1] is the thermal energy of a photon mode. Consequently, the energy emitted per unit surface area and per unit frequency, also called spectral radiance, of a black body into three-dimensional (3D) space is given by

\[ I_{BB}(ω)dω = \frac{1}{4π} \frac{cu(ω)}{ω^2} \frac{ω^3}{4π^3 C^2} \Theta(ω)dω. \]  
(1)

The total energy density u can then be obtained by integrating over all frequencies and angles over the hemisphere, leading to the Stefan-Boltzmann law for the energy density of black-body radiation,

\[ u_{BB} = \left( \frac{8π^5 k_B^4}{15c^3 h^3} \right) T^4 = a_{BB} T^4, \]  
(2)

with \( a_{BB} = 7.566 \times 10^{-16} \) Jm⁻³K⁻⁴. The total power emitted per unit surface area \( P/A \) of a black-body is

\[ I_{BB} = \frac{P}{A} = \int_0^∞ I_{BB}(ω)dω = \frac{1}{4π} \int_0^∞ \frac{ω^3}{4π^3 C^2} \Theta(ω) dω. \]

\[ = π \int_0^∞ I_{BB}(ω)dω = \frac{1}{4π} uc \]

\[ = \frac{a_{BB} c}{4π} T^4 = b_{BB} T^4 = \left( \frac{π^2 k_B^4}{60c^2 h^3} \right) T^4, \]  
(3)

where \( b_{BB} = 5.67 \times 10^{-8} \) Wm⁻²K⁻⁴ is the Stefan-Boltzmann constant. The factor \( \cos θ \) is due to the fact that black bodies are Lambertian radiators.

In recent years, several methods have been implemented for achieving a spectrally selective emittance, in particular narrowband emittance, which increases the coherence of the emitted photons. One possibility is to use a material that exhibits optical resonances due to the band structure or due to confinement of the charge carriers.[2] Another method is to use structural optical resonances to enhance and/or suppress the emittance. Recently, photonic crystal structures have been used to implement passive pass band filters that reflect the thermal emission.
at wavelengths that match the photonic bandgap. Alternatively, a truncated photonic crystal can be used to enhance the emittance at resonant frequencies.

Recent experiments have shown that it is possible to generate infrared (IR) emission by means of Joule heating created by means of a bias voltage applied to graphene on a SiO$_2$/Si substrate. In order to avoid the breakdown of the graphene sheet at around $T = 700$ K, the graphene sheet can be encapsulated between hexagonal boron nitride (h-BN) layers, which remove efficiently the heat from graphene. The top layer protects it from oxidation. In this way, the graphene sheet can be heated up to $T = 1600$ K or even above $T = 2000$ K.

Kim et al. and Luo et al. demonstrated broadband visible emission peaked around a wavelength of $\lambda = 725$ nm. By using a photonic crystal substrate made of Si, Shiue et al. demonstrated narrowband near-IR emission peaked at around $\lambda = 1600$ nm with an emittance of 0.07. To the best of our knowledge, there are neither theoretical nor experimental studies on spectrally selective thermal emission from graphene in the mid-IR range.

Here, we present the proof of concept of a method to tune the spectrally selective thermal emission from nanopatterned graphene (NPG) by means of a gate voltage to tune the spectrally selective thermal emission from graphene in the mid-IR range.

The localized surface plasmon resonance (LSP) frequency of the hole can be determined from the equation

$$\omega = \frac{2\alpha d \pi (\pi/2 - 1)}{3} \left( \frac{\varepsilon(\omega) - \varepsilon_m}{\varepsilon_m + L_1(\varepsilon(\omega) - \varepsilon_m)} \right),$$

respectively, for which the in-plane polarizabilities lies in the plane of the graphene sheet that is parallel to the $xy$-plane. $\varepsilon(\omega)$ is the dielectric function of graphene. We assumed that the thickness $d$ of the graphene sheet is much smaller than the size of the elliptic hole. The geometrical factors in this limit are

$$L_1 \approx abd \int_{\eta_1}^{\infty} \frac{d\eta'}{(\eta' + a^2)R_{\eta'}},$$

$$L_2 \approx abd \int_{\eta_1}^{\infty} \frac{d\eta'}{(\eta' + b^2)R_{\eta'}}.$$

In the case of a circular hole of diameter $a$ the polarizability simplifies to

$$\alpha_\parallel(\omega) = \frac{2a^2 \pi (\pi/2 - 1)}{3} \left( \frac{\varepsilon(\omega) - \varepsilon_m}{\varepsilon_m + L_\parallel(\varepsilon(\omega) - \varepsilon_m)} \right).$$

The localized surface plasmon resonance (LSP) frequency of the hole can be determined from the equation

$$\varepsilon_m + L_\parallel(\varepsilon(\omega) - \varepsilon_m) = 0,$$

the condition for which the denominator of $\alpha_\parallel$ vanishes.

Using the linear dispersion relation, the intraband optical conductivity is

$$\sigma_{\text{intra}}(\omega) = \frac{e^2}{\pi \hbar^2} \frac{2k_B T}{\tau - i\omega} \ln \left[ \cosh \left( \frac{\varepsilon_F}{2k_B T} \right) \right],$$

which in the case of $\varepsilon_F \gg k_B T$ is reduced to

$$\sigma_{\text{intra}}(\omega) = \frac{e^2}{\pi \hbar^2} \frac{\varepsilon_F}{\tau - i\omega} = \frac{2\varepsilon_m \omega_p^2}{\pi \hbar^2 (\tau - i\omega)}.$$
where $\tau$ is determined by impurity scattering and electron-phonon interaction $\tau^{-1} = \tau_{imp}^{-1} + \tau_{e-ph}^{-1}$. Using the mobility $\mu$ of the NPG sheet, it can be presented in the form $\tau^{-1} = e\nu_p^2/(\mu E_F)$, where $\nu_p = 10^6$ m/s is the Fermi velocity in graphene. $\omega_p = \sqrt{e^2\epsilon_F/2\epsilon_m}$ is the bulk graphene plasma frequency.

It is well-known by now that hydrodynamic effects play an important role in graphene because the Coulomb interaction collision rate is dominant, i.e., $\tau_{ee}^{-1} \gg \tau_{imp}^{-1}$ and $\tau_{ee}^{-1} \gg \tau_{e-ph}^{-1}$, which corresponds to the hydrodynamic regime. $\tau_{imp}^{-1}$ and $\tau_{e-ph}^{-1}$ are the electron-impurity and electron-phonon collision rates. Since for large absorbance and emittance, we choose a large Fermi energy, we are in the Fermi liquid regime of the graphene sheet. Taking the hydrodynamic correction into account, we also consider the hydrodynamically adjusted intraband optical conductivity,\(^{13,14}\)

$$\sigma_{\text{HD}}^{\text{intra}}(\omega) = \frac{\sigma_{\text{intra}}(\omega)}{1 - \eta^2 \frac{\omega_p^2}{\omega^2}},$$  \hspace{1cm} (13)

where $\eta^2 = \beta^2 + D^2\omega(\gamma + i\omega)$, $\beta^2 \approx \frac{3}{4} \nu_p^2$ is the intraband pressure velocity, $D \approx 0.4$ $\mu$m is the diffusion length in graphene, and $\gamma = \tau^{-1}$ is the relaxation rate. Interestingly, the optical conductivity becomes $k$-dependent and nonlocal. Also, below we will conjecture that the diffusion length $D$ must be frequency-dependent.

Note that since $\epsilon = 1 + \chi$, where $\chi$ is the susceptibility, it is possible to replace $\epsilon'' = \chi''$. Alternatively, using the formula of the polarizability $\alpha = \epsilon_0\chi$ we can write $\epsilon'' = \alpha''/\epsilon_0$. The dielectric function for graphene is given by\(^{11,12}\)

$$\epsilon_{\parallel}(\omega) = \epsilon_g - \frac{i\sigma_{2D}(\omega)}{\epsilon_0\omega d},$$  \hspace{1cm} (14)

where $\epsilon_g = 2.5$ is the dielectric constant of graphite and $d$ is the thickness of graphene. Inserting this formula into Eq. (10) gives

$$\epsilon_m + L_{\|}[\epsilon_g - i\frac{e^2}{\pi\hbar^2 \tau^2 \epsilon_0\omega d} - i\frac{\epsilon_g}{\epsilon_0d} - \epsilon_m] = 0,$$  \hspace{1cm} (15)

Solving for the frequency and using the real part we obtain the LSP frequency,

$$\text{Re}\omega_{\text{LSP}} = \frac{2L_{\|}\epsilon_m\omega_p^2\tau}{\pi\hbar^2 \left[L_{\|}^2 + d^2\epsilon_0^2 \left[L_{\|}(\epsilon_g - \epsilon_m) + \epsilon_m \right]^2 \right]},$$  \hspace{1cm} (16)

which is linear in the Fermi energy $\epsilon_F$.

(31) for the bare NPG sheet and the whole structure including cavity, respectively. The dotted (green) line exhibits a blue-shift due to the hydrodynamic correction shown in Eq (13) with } D(\nu = 30 \text{ THz}) \approx 0. \text{ The blue-shifted dashed (magenta) curve and the blue-shifted dot-dashed (cyan) curve are the RPA-corrected LSP peaks due to the Coulomb interaction and the Coulomb interaction including electron-phonon interaction with the optical phonons of graphene, boron nitride, and Si$_3$N$_4$. This NPG sheet emits into the atmospheric transparency window between 3 and 5 } \mu\text{m.}](image)
where \( G_{j,j'} \) is the dipole-dipole interaction tensor.

Using Bloch’s theorem \( p_j = p_0 \exp(i k_0 |R_j|) \), the effective dipole moment becomes

\[
\tilde{p}_j = p_j + \alpha \sum_{j' \neq j} G_{j,j'} \tilde{p}_{j'} ,
\]

(17)

where \( G_{j,j'} \) is the dipole-dipole interaction tensor. Using Bloch’s theorem \( p_j = p_0 \exp(i k_0 |R_j|) \), the effective dipole moment becomes

\[
\tilde{p}_0 = p_0 + \tilde{p}_0 \alpha \sum_{j' \neq j} G_{j,j'} e^{i k_0 (|R_j| - |R_{j'}|)} .
\]

(18)

for each site \( j \), and thus

\[
\tilde{p}_0 = \frac{p_0}{1 - \alpha G}.
\]

(19)

The lattice sum over the dipole-dipole interaction tensor

\[
\tilde{G} = \sum_{j' \neq j} G_{j,j'} e^{i k_0 (R_j - R_{j'})}
\]

(20)

where \( P \) is the lattice period,

\[
S = \frac{2 \pi k}{\Omega_0} \times \left\{ \begin{array}{ll}
\arccos \theta & \text{for } s \text{ polarization}, \\
\cos \theta & \text{for } p \text{ polarization},
\end{array} \right.
\]

(21)

\[\Omega_0 = \text{the unit-cell area, and the real part is valid for periods much smaller than the wavelength. The factor } g = 5.52 (g = 4.32) \text{ for hexagonal (square) lattice.} \]

The electric field created by the effective dipole moment is determined by

\[
\tilde{p}_0 = \tilde{a} E,
\]

(22)

from which we obtain the effective polarizability of a hole in the coupled dipole approximation (CDA),

\[
\tilde{a} = \frac{\alpha}{1 - \alpha \tilde{G}}.
\]

(23)

This formula is the same as in Refs. [12] and [13] where the absorption of electromagnetic waves by arrays of dipole moments and graphene disks were considered, respectively. Thus, our result corroborates Kirchhoff’s law (see below). Consequently, we obtain the same reflection and transmission amplitudes as in Ref. [13], i.e.

\[
r = \frac{\pm i S}{\alpha^{-1} - \tilde{G}}, \quad t = 1 + r,
\]

(24)

where the upper (lower) sign and \( S = 2 \pi \omega/\epsilon \Omega_0 \cos \theta \) \( (S = 2 \pi \omega \cos \theta / \epsilon \Omega_0) \) apply to \( s \) \((p) \) polarization. Thus, the emittance and absorbance of the bare NPG sheet are given by

\[
\epsilon_g = A_g = 1 - |r|^2 - |t|^2.
\]

(25)

The coupling to the interface of the substrate with reflection and transmission amplitudes \( r_0 \) and \( t_0 \), respectively, which is located basically at the same position as the

NPG sheet, yields the combined reflection and transmission amplitudes\(^{[18]}\)

\[
R = r + \frac{tt' r_0}{1 - r_0 r'}, \quad T = \frac{tt_0}{1 - r_0 r'},
\]

(26)

where \( r' \) and \( t' = 1 - r \) are the reflection and transmission amplitudes in backwards direction, respectively.

If we include also the whole substrate including cavity and Au mirror, we need to sum over all possible optical paths in the Fabry-Perot cavity, yielding

\[
R_{FP} = R + TT' r_{Au} e^{i \delta} \sum_{m=0}^{\infty} r_m^m ,
\]

(27)

with

\[
r_m = r_{Au} R' e^{i \delta},
\]

(28)

where \( r_{Au} \) is the complex reflection amplitude of the Au mirror in the IR regime. \( \delta = 2 k L \cos \theta \) is the phase accumulated by one back-and-forth scattering inside the Fabry-Perot cavity of length \( L \). \( k \approx n_{SU} k_0 \) is the wavenumber inside the cavity for an external EM wave with wavenumber \( k_0 = 2 \pi / \lambda \). Since the sum is taken over a geometric series, we obtain

\[
R_{FP} = R + \frac{TT' r_{Au} e^{i \delta}}{1 - r_{Au} R' e^{i \delta}}.
\]

(29)

Since the transmission coefficient through the Au mirror can be neglected, we obtain the emittance \( \epsilon \) and absorbance \( A \) including cavity, i.e.

\[
\epsilon_{FP} = \epsilon_{Au} = 1 - |R_{FP}|^2.
\]

(30)

(31)
possible to express the fluctuating electric field generated inside the two-dimensional graphene sheet, we can write
\[ \rho_j = \frac{e}{2} \sum_{\nu} \varepsilon_{\nu} \delta_\nu \Im(\varepsilon_{\nu}) \delta_\nu \delta(r_{\nu\nu}) - \delta(r_{\nu\nu} - R_j \omega) \]
where \( R_j = (x_j, y_j) \) are the positions of the holes in the graphene sheet.

Consequently, we have
\[ \delta \mathbf{E}(r, \omega) = \omega^2 \mu_0 \delta \mathbf{p}_0(\omega) \sum_j G(r, R_j; \omega). \] (36)

The dyadic Green function is defined as
\[ \hat{G}(r, r'; \omega) = \left[ \mathbb{1} + \frac{1}{k(\omega)^2} \nabla \nabla \right] G(r, r'; \omega) \] (37)
with the scalar Green function given by
\[ G(r, r'; \omega) = \frac{e^{-i k(\omega)|r - r'|}}{4\pi |r - r'|}, \] (38)
and \( k(\omega)^2 = (\omega^2/c^2)[\varepsilon_{xx}(\omega), \varepsilon_{yy}(\omega), \varepsilon_{zz}(\omega)] \).

Then, the fluctuation-dissipation theorem can be recast into the forms
\[ \langle \delta \mathbf{p}_0(r_{0\nu}, \omega) \delta \mathbf{p}_0^*(r'_{0\nu}, \omega') \rangle = \frac{\sigma_{\nu\nu}^2(R_{0i}; \omega)}{\omega^2} \Theta(\omega) \delta(\omega - \omega') \times \delta(r_{0\nu} - r'_{0\nu}), \] (39)
noting that the dielectric tensor \( \varepsilon_{ij} \) is diagonal.

![Diagram](image)

**Figure 7.** Spectral radiance of NPG including cavity, as shown in in Figs. 1 and 2, as a function of wavelength \( \lambda \) with Fermi energy \( E_F = -1.0 \) eV, mobility \( \mu = 3000 \) V/cm\( \cdot \)s, hole diameter of \( a = 90 \) nm, and period of \( P = 150 \) nm at 1300 K, 1700 K, and 2000 K.

Since the energy density of the emitted electric field at the point \( \mathbf{r} \) is

\[
\langle \delta \mathbf{E}_r(\mathbf{r}, \omega) \delta \mathbf{E}_i(\mathbf{r}, \omega') \rangle \]

we can write the spectral radiance as

\[
I(\mathbf{r}, \omega) = \frac{\omega^2}{4\pi^2 \varepsilon_0} \frac{1}{N} \sum_{\mu, \nu = x, y, z} |G_{\mu\nu}(\mathbf{r}, \mathbf{R}_j; \omega)|^2 \times \Theta(\omega) \sigma^{2D}_{\mu\nu}(\mathbf{R}_j, \omega)
\]

\[
= \frac{\omega^2}{4\pi^2 \varepsilon_0} \Theta(\omega) \sigma^{2D}_{\mu\nu}(\mathbf{R}_j, \omega) \sum_{\mu, r} |G_{\mu r}(\mathbf{r}, \mathbf{R}_0; \omega)|^2
\]

assuming that the dipole current of the LSP is in the plane of the graphene sheet, i.e. the xy-plane, and the polarizability is isotropic, i.e. \( \sigma^{2D}_{\mu\nu} = \sigma^{2D}_{\nu\mu} = \sigma^{2D} \), and the same for all holes. \( N \) is the number of holes. In order to obtain the spectral radiance in the far field, we need to integrate over the spherical angle. Using the results from the Supplementary Information, we obtain

\[
I_\infty(\omega) = \frac{\omega^2 \Theta(\omega)}{3\pi^2 \varepsilon_0 c^3} \sigma^{2D}_{\mu\nu}(\omega)
\]

\[
= \frac{\omega^2 \Theta(\omega)}{3\pi^2 c^2} A^{2D}(\omega),
\]

where we used the definition of the absorbance of a 2D material, i.e.

\[
A_{2D}(\omega) = (1/\varepsilon_0 c) \text{Re} \sigma_{2D}(\omega) = (1/\varepsilon_0 c) \sigma^{2D}_i(\omega),
\]

with 2D complex conductivity \( \sigma_{2D}(\omega) \). According to Kirchhoff’s law, emittance \( \epsilon(\omega) \), absorbance \( A(\omega) \), reflectance \( R(\omega) \), and transmittance \( T(\omega) \) are related by

\[
\epsilon(\omega) = 1 - R(\omega) - T(\omega),
\]

from which we obtain the grey-body thermal emission formula

\[
I_\infty(\omega) = \frac{\omega^2 \Theta(\omega)}{3\pi^2 c^2} \epsilon^{2D}_{\parallel}(\omega),
\]

whose prefactor bears strong similarity to Planck’s black body formula in Eq. (1).

![Diagram](image)

**Figure 8.** Temperature distribution inside the NPG sheet for various values of the bias voltage \( V_{SD} \), calculated by means of COMSOL. As the bias voltage is increased, the maximum of temperature shifts away from the center of the NPG sheet due to the Peltier effect.

Using FDTD to calculate the emittance \( \epsilon^{2D}_{\parallel}(\omega) \), we evaluated the grey-body thermal emission according to
Eq. (46) for the thermal emitter structure based on NPG shown in Figs. 1 and 2. Using COMSOL, we calculated the temperature distribution inside the NPG sheet, as shown in Fig. 8 when a bias voltage $V_{3D}$ is applied, which gives rise to Joule heating. Our results are shown in Figs. 3, 7, and 9 for the temperatures 1300 K, 1700 K, and 2000 K of NPG. After integrating over the wavelength under the curves, we obtain the following thermal emission power per area:

| Resonance wavelength | Power per area  |
|----------------------|----------------|
| 4 μm                 | 11.221 W/m²   |
| 7 μm                 | 9820 W/m²     |
| 10 μm                | 6356 W/m²     |

Figure 9. Spectral radiance of NPG including cavity, as shown in Figs. 1 and 2, as a function of wavelength $\lambda$ with Fermi energy $E_F = -1.0$ eV, mobility $\mu = 3000$ V/cm²s, hole diameter of $a = 300$ nm, and period of $P = 450$ nm at 1300 K, 1700 K, and 2000 K.

Let us consider the dependence of the thermal emission of NPG on the angle $\theta$. Integrating over $r^2 \varphi$, we obtain

$$I(\theta, \omega) = \frac{\omega^2}{4\pi c^2} \Theta(\omega) \frac{11 + \cos(2\theta)}{16\pi} \epsilon_d^2(\omega),$$

which is a clear deviation from a Lambert radiator. The pattern of the thermal radiation can be determined by

$$\hat{I}(\theta) = \frac{\int_0^{2\pi} I(r, \omega) r^2 d\varphi}{\int_0^{2\pi} \int_0^\infty I(r, \omega) r^2 \sin \theta d\theta d\varphi} = \frac{3}{64} [11 + \cos(2\theta)],$$

which is shown in Fig. 10. Interestingly, since we assumed that thermal emission is completely incoherent [see Eq. (42)] the thermal emission from NPG is only weakly dependent on the emission angle $\theta$, which can be clearly seen in Fig. 10.

However, the assumption that thermal emission of radiation is incoherent is not always true. Since Kirchhoff’s law is valid, thermal sources can be coherent. After theoretical calculations predicted that long-range coherence may exist for thermal emission in the case of resonant surface waves, either plasmonic or phononic in nature, experiments showed that a periodic microstructure in the polar material SiC exhibits coherence over many wavelengths and radiates in well-defined and controlled directions. Here we show that the coherence length of a graphene sheet patterned with circular holes can be as large as 150 μm due to the plasmonic wave in the graphene sheet, thereby paving the way for the creation of phased arrays made of nanoantennas represented by the holes in NPG.

The coherence of thermal emission can be best understood by means of a nonlocal response function. First, we choose the nonlocal hydrodynamic response function in Eq. (13). Using the 2D version of the fluctuation-dissipation theorem in Eq. (33), we obtain the nonlocal fluctuation-dissipation theorem in the hydrodynamic approximation,

$$\langle \delta \hat{J}_\mu(r_||, \omega) \delta \hat{J}_\nu(r'||, \omega') \rangle = \sigma^{\text{HD}}_{\mu\nu}(\Delta r_||, \omega) \Theta(\omega) \delta(\omega - \omega') = \frac{1}{D} \int_0^\infty dk_|| \sigma^{\text{intra}}(\omega) e^{-ik_|| \Delta r_||} \Theta(\omega) \delta(\omega - \omega')$$

$$= \sigma^{\text{intra}}(\omega) \frac{\omega \sqrt{\pi/2}}{D\eta} \sin \left( \frac{\omega \Delta r_||}{\eta} \right) \Theta(\omega) \delta(\omega - \omega'),$$

where $\Delta r_|| = r_|| - r'_||$ and $\eta^2 = \beta^2 + D^2(\gamma + \omega)$. This result suggests that the coherence length is given approximately by $D$, which according to Ref. 13 would be $D \approx 0.4$ μm. However, the resulting broadening of the LSP resonance peaks would be very large and therefore in complete contradiction to the experimental measurements of the LSP resonance peaks in Refs. 11, 24, and 25. Thus, we conclude that the hydrodynamic diffusion...
length must be frequency-dependent with \( D(\nu = 0) = 0.4 \mu \text{m} \). Using the Fermi velocity of \( v_F = 10^6 \text{ m/s} \) and a frequency of \( \nu = 30 \text{ THz} \), the average oscillation distance is about \( L = v_F \nu^{-1} = 0.033 \mu \text{m} \), which is much smaller than \( D(\nu = 0) \) in graphene. Thus we can approximate \( D(\nu = 30 \text{ THz}) = 0 \). We conjecture that there is a crossover for \( D \) into the hydrodynamic regime when the frequency is reduced below around \( \nu_0 = 1 \) to 3 THz, below which the hydrodynamic effect leads to a strong broadening of the LSP peaks for NPG. Consequently, the viscosity of graphene should also be frequency-dependent and a crossover for the viscosity should happen at about the same frequency \( \nu_0 \). We plan to elaborate this conjecture in future work. Future experiments could corroborate our conjecture by measuring the absorbance or emittance as a function of wavelength for varying scale of patterning of the graphene sheet.

\[
\sigma^{\text{RPA}}(q, \omega) = \frac{ie^2 \omega}{q^2} \chi(q, \omega)
\]

where the coherence length in RPA approximation is

\[
C_{\text{RPA}} = \frac{e^2|\epsilon_F|}{2\pi \hbar^2 \epsilon_0 \gamma \omega^2},
\]

and the coherence wavenumber is given by

\[
K_{\text{RPA}} = \frac{2\pi \hbar^2 \epsilon_0 \omega^2}{e^2|\epsilon_F|}.
\]

For simplicity, we switch now to a square lattice of holes. In the case of the LSP resonance for a square lattice of holes at \( \lambda = 10 \mu \text{m} \), corresponding to \( \nu = 30 \text{ THz} \), \( \epsilon_F = -1.0 \text{ eV} \), \( \omega = 2\pi \nu \), and \( \gamma = ev_F^2/(\mu E_F) = 0.3 \text{ THz} \) for \( \mu = 3000 \text{ cm}^2\text{V}^{-1}\text{s}^{-1} \), which results in a coherence length of \( C_{\text{RPA}} = 3 \mu \text{m} \). This result is in reasonable agreement with the full width at half maximum (FWHM) values of the widths of the LSP resonance peaks in Refs.\[11, 24, \text{ and } 25\]. This coherence length would allow to preserve coherence for a linear array of period \( P = 300 \mu \text{m} \) and \( C_{\text{RPA}}/P = 10 \) holes. In order to show the coherence length that can be achieved with graphene, we can consider a suspended graphene sheet with a mobility of \( \mu = 15000 \text{ cm}^2\text{V}^{-1}\text{s}^{-1} \). Then the coherence length increases to a value of \( C_{\text{RPA}} = 13 \mu \text{m} \), which would allow for coherence over a linear array with \( C_{\text{RPA}}/P = 43 \) holes.

in the low-temperature and low-frequency approximation, one obtains Eq. \[\text{[12]}\]. Now, let us use the full polarization in RPA approximation including only the Coulomb interaction,

\[
\chi^{\text{RPA}}(q, \omega) = \frac{\chi^0(q, \omega)}{1 - v_c(q)\chi^0(q, \omega)},
\]

from which we obtain

\[
\sigma^{\text{RPA}}(q, \omega) = \frac{ie^2 \omega}{q^2} \chi(q, \omega)
\]

\[
= \frac{ie^2 \omega \epsilon_F}{\pi \hbar^2 \omega (\omega + i\tau^{-1}) - e^2 \epsilon_F/2\epsilon_0 q^2},
\]

which introduces the nonlocal response via the Coulomb interaction in the denominator. After taking the Fourier transform, we obtain the nonlocal fluctuation-dissipation theorem in RPA approximation,

\[
\left\langle \delta J_\mu(r||, \omega)\delta J_\nu(r'||, \omega') \right\rangle = \epsilon^{\text{RPA}}_{\mu\nu}(\Delta r||, \omega)\Theta(\omega)\delta(\omega - \omega')
\]

\[
= \frac{\sqrt{2\pi \epsilon_0 \omega^3}}{\epsilon_F^{\text{RPA}}} e^{iK_{\text{RPA}}\Delta r|| - \frac{\Delta r||^2}{2\epsilon_F^{\text{RPA}}}} \Theta(\omega)\delta(\omega - \omega'),
\]

Figure 11. Coherence length \( C_{\text{FDTD}} \) and coherence time \( \tau_{\text{FDTD}} \) of emitted photons, extracted from the full-width half-maximum (FWHM) of the spectral radiances shown in Figs. \[\text{6} \] and \[\text{9} \].

Next, let us consider the coherence of thermal emission by means of the nonlocal optical conductivity in the RPA approximation. Using the general formula

\[
\sigma(q, \omega) = \frac{ie^2 \omega}{q^2} \chi^0(q, \omega),
\]

with

\[
\chi^0(q, \omega) \approx \frac{\epsilon_F q^2}{\pi \hbar^2 \omega (\omega + i\tau^{-1})}
\]

in the low-temperature and low-frequency approximation, one obtains Eq. \[\text{[12]}\]. Now, let us use the full polarization in RPA approximation including only the Coulomb interaction,
and coherence time $\tau_{\text{FDTD}}$ of thermally emitted photons by means of the full-width half-maximum (FWHM) of the spectral radiances shown in Figs. 6, 7 and 9. Our results are shown in Fig. 11. The coherence length of the thermally emitted photons can reach up to $C_{\text{FDTD}} = 150 \mu m$ at a resonance wavelength of $\lambda = 4 \mu m$. This means that the coherence length of the thermally emitted photons is about 37 times larger than the wavelength.

Thus, the latter large coherence length allows for the coherent control of a 150x150 square array of holes with period $P = 45 \text{ nm}$, individually acting as nanoantennas, that can be used to create a phased array of nanoantennas. One of the intriguing properties of a phased array is that it allows to control the directivity of the emission of photons, which is currently being implemented for large 5G antennas in the 3 to 30 GHz range. The beamsteering capability of our NPG sheet is shown in Fig. 12. In contrast, our proposed phased array based on NPG can operate in the 10 to 100 THz range.

The temporal control of the individual phases of the holes requires an extraordinary fast switching time of around 1 ps, which is not feasible with current electronics. However, the nonlocal response function reveals a spatial phase shift determined by the coherence wavenumber $K_{RPA}$, which is independent of the mobility of graphene.

In the case of the LSP resonance at $\lambda = 4 \mu m$, we obtain $\lambda_{RPA} = 2\pi/K_{RPA} = 6 \mu m$, resulting in a minimum phase shift of $2\pi P/\lambda_{RPA} = 0.042 = 2.4^\circ$ between neighboring holes, which can be increased to a phase shift of $9.7^\circ$ by decreasing the Fermi energy to $E_F = -0.25 \text{ eV}$. Thus, the phase shift between neighboring holes can be tuned arbitrarily between $2.4^\circ$ and $9.7^\circ$ by varying the Fermi energy between $E_F = -1.0 \text{ eV}$ and $E_F = -0.25 \text{ eV}$. Fig. 12 shows the capability of beamsteering for our proposed structure by means of directional thermal emission, which is tunable by means of the gate voltage applied to the NPG sheet.

Due to the full control of directivity with angle of emission between $\theta = 12^\circ$ and $\theta = 80^\circ$ by tuning the Fermi energy in the range between $\epsilon_F = -1.0 \text{ eV}$ and $\epsilon_F = -0.25 \text{ eV}$, thereby achieving beamsteering by means of the gate voltage, our proposed mid-IR light source based on NPG can be used not only in a vertical setup for surface emission, but also in a horizontal setup for edge emission, which is essential for nanophotonics applications.

In conclusion, we have demonstrated in our theoretical study that NPG can be used to develop a plasmonically enhanced mid-IR light source with spectrally tunable selective thermal emission. Most importantly, the LSPs along with an optical cavity increase substantially the emittance of graphene from about 2% for pristine graphene to 80% for NPG, thereby outperforming state-of-the-art graphene light sources working in the visible and NIR by at least a factor of 100. Combining our proposed mid-IR light source based on patterned graphene with our demonstrated mid-IR detector based on NPG\cite{Weber2018}, we are going to develop a mid-IR spectroscopy and detection platform based on patterned graphene that will be able to detect a variety of molecules that have mid-IR vibrational resonances, such as CO, CO$_2$, NO, NO$_2$, CH$_4$, TNT, H$_2$O$_2$, acetone, TATP, Sarin, VX, etc. In particular, a recent study showed that it is possible to detect the hepatitis B and C viruses label-free at a wavelength of around $6 \mu m$\cite{Shiu2019}. Therefore, we will make great effort to demonstrate that our platform will be able to detect with high sensitivity and selectivity the COVID-19 virus and other viruses that pose a threat to humanity.

I. SUPPLEMENTARY INFORMATION

A. Spectrally Selective Thermal Emission

Kirchhoff’s law of thermal radiation states that emittance $\epsilon$ is equal to absorbance $A$, i.e.

$$\epsilon(\omega, \theta, \phi, T) = A(\omega, \theta, \phi, T).$$  (57)

In the case of a black body $\epsilon(\omega, \theta, \phi, T) = A(\omega, \theta, \phi, T) = 1$. Pristine graphene has a very small absorbance of only $A = 0.023$ and is a nearly transparent body. Shiu et al. used a photonic crystal structure to filter the thermal emission from pristine graphene with an emittance of around $A = 0.071^{10}$ Their spectral radiance is shown in Fig. 13 and exhibits peaks at around $\lambda = 1.55 \mu m$ at a temperature of $T = 2000 \text{ K}$. After integrating the spectral radiance under the curve, one obtains an emission power per area of about $P/A = 100 \text{ W/m}^2$, which is about 100 times weaker than our proposed thermal radiation source based on NPG at $T = 2000 \text{ K}$. Our proposed thermal mid-IR source features an emission power
Figure 13. Theoretical fit to spectral radiance presented in Ref. 10. Shiue et al. used a photonic crystal structure to filter the thermal emission from pristine graphene with an emittance of around $\varepsilon = 0.07$. Integrating the spectral radiance under the curve gives a value of about $P/A = 100$ W/m$^2$, which is about 100 times weaker than our proposed thermal radiation source based on NPG.

per area of about $P/A = 10^4$ W/m$^2$ at $T = 2000$ K. In addition, our proposed thermal mid-IR source features frequency-tunability and beamsteering by means of a gate voltage applied to the NPG sheet.

Using FDTD to calculate the emittance $\varepsilon_{2D}(\omega)$, we evaluated the grey-body thermal emission according to Eq. (46) for the thermal emitter structure based on NPG shown in Figs. 1 and 2. Our results for the temperature $T = 300$ K of NPG are shown in Figs. 14 and 15. In these figures we compare our results for NPG with the results for pristine graphene and black body radiation.

Figure 14. The NPG sheet allows for spectrally selective thermal emission at around $\lambda = 4.5$ µm for a period of $P = 45$ nm and a hole diameter of $a = 30$ nm.

B. Ellipsoidal Coordinates

For determining the EM properties of an infinitesimally thin conducting elliptical disk of radius $R$ or an infinitesimally thin conducting plane with a elliptical hole, including coated structures, it is most convenient to perform the analytical calculations in the ellipsoidal coordinate system $(\xi, \eta, \zeta)$ which is related to the Cartesian coordinate system through the implicit equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

for $a > b > c$. The cubic roots $\xi, \eta,$ and $\zeta$ are all real in the ranges

$$-a^2 \leq \zeta \leq -b^2, \quad -b^2 \leq \eta \leq -c^2, \quad -c^2 \leq \xi < \infty,$$

which are the ellipsoidal coordinates of a point $(x, y, z)$. The surfaces of constant $\xi, \eta,$ and $\zeta$ are ellipsoids, hyperboloids of one sheet, and hyperboloids of two sheets, respectively, all confocal with the ellipsoid defined by

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Each point $(x, y, z)$ in space is determined by the intersection of three surfaces, one from each of the three families, and the three surfaces are orthogonal to each other. The transformation between the two coordinate systems is given by the solutions of Eq. (58), i.e.

$$x = \pm \sqrt{\frac{(\xi + a^2)(\eta + a^2)(\zeta + a^2)}{(b^2 - a^2)(c^2 - a^2)}},$$

$$y = \pm \sqrt{\frac{(\xi + b^2)(\eta + b^2)(\zeta + b^2)}{(c^2 - b^2)(a^2 - b^2)}},$$

$$z = \pm \sqrt{\frac{(\xi + c^2)(\eta + c^2)(\zeta + c^2)}{(a^2 - c^2)(b^2 - c^2)}},$$

for $a > b > c$. The cubic roots $\xi, \eta,$ and $\zeta$ are all real in the ranges

$$-a^2 \leq \zeta \leq -b^2, \quad -b^2 \leq \eta \leq -c^2, \quad -c^2 \leq \xi < \infty,$$

which are the ellipsoidal coordinates of a point $(x, y, z)$. The surfaces of constant $\xi, \eta,$ and $\zeta$ are ellipsoids, hyperboloids of one sheet, and hyperboloids of two sheets, respectively, all confocal with the ellipsoid defined by

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$
For the transformation from cartesian to ellipsoidal coordinates, the length elements in ellipsoidal coordinates read:

\[ d^2 = h_1^2 dx^2 + h_2^2 dy^2 + h_3^2 dz^2, \]

\[ h_1 = \sqrt{\frac{(\xi - \eta)(\xi - \zeta)}{2R_\xi}}, \]

\[ h_2 = \sqrt{\frac{\eta}{2R_\eta}}, \]

\[ h_3 = \sqrt{\frac{(\zeta - \xi)(\zeta - \eta)}{2R_\zeta}}, \]

\[ R_w^2 = (u + a^2)(u + b^2)(u + c^2), \quad u = \xi, \eta, \zeta. \]

For the transformation from cartesian to ellipsoidal coordinates, one can use the following system of equations:

\[ \xi = \frac{\partial x}{\partial \xi} = \frac{1}{2} \sqrt{\frac{(a^2 + \eta)(a^2 + \zeta)}{(a^2 + \xi)(a^2 - b^2)(a^2 - c^2)}}, \]

\[ \eta = \frac{\partial x}{\partial \eta} = \frac{1}{2} \sqrt{\frac{(a^2 + \xi)(a^2 + \zeta)}{(a^2 + \eta)(a^2 - b^2)(a^2 - c^2)}}, \]

\[ \zeta = \frac{\partial x}{\partial \zeta} = \frac{1}{2} \sqrt{\frac{(a^2 + \eta)(a^2 + \xi)}{(a^2 + \eta)(a^2 - b^2)(a^2 - c^2)}}, \]

\[ \frac{\partial \eta}{\partial \xi} = \frac{1}{2} \sqrt{\frac{(b^2 + \eta)(b^2 + \zeta)}{(b^2 + \xi)(b^2 - a^2)(b^2 - c^2)}}, \]

\[ \frac{\partial \eta}{\partial \eta} = \frac{1}{2} \sqrt{\frac{(b^2 + \xi)(b^2 + \zeta)}{(b^2 + \eta)(b^2 - a^2)(b^2 - c^2)}}, \]

\[ \frac{\partial \eta}{\partial \zeta} = \frac{1}{2} \sqrt{\frac{(b^2 + \xi)(b^2 + \eta)}{(b^2 + \eta)(b^2 - a^2)(b^2 - c^2)}}, \]

\[ \frac{\partial \zeta}{\partial \xi} = \frac{1}{2} \sqrt{\frac{(c^2 + \eta)(c^2 + \zeta)}{(c^2 + \xi)(c^2 - a^2)(c^2 - b^2)}}, \]

\[ \frac{\partial \zeta}{\partial \eta} = \frac{1}{2} \sqrt{\frac{(c^2 + \xi)(c^2 + \zeta)}{(c^2 + \eta)(c^2 - a^2)(c^2 - b^2)}}, \]

\[ \frac{\partial \zeta}{\partial \zeta} = \frac{1}{2} \sqrt{\frac{(c^2 + \xi)(c^2 + \eta)}{(c^2 + \xi)(c^2 - a^2)(c^2 - b^2)}}. \]

The coordinate \( \eta \) is constant on the surfaces of oblate spheroids defined by

\[ \frac{x^2 + y^2}{(R \cosh \eta)^2} + \frac{z^2}{(R \sinh \eta)^2} = 1 \]

The surface associated with the limit \( \eta \to 0 \) is an infinitesimally thin circular disk of radius \( R \). In contrast, the surface in the limit \( \eta \to \infty \) is a sphere of radius \( r = R \cosh \eta \approx R \sinh \eta \). Thus, the Laplace equation in ellipsoidal coordinates reads

\[ \Delta \Phi = \frac{4}{(\xi - \eta)(\zeta - \xi)(\zeta - \eta)} \left[ (\eta - \zeta) R_\xi \frac{\partial \Phi}{\partial \xi} (R_\xi \frac{\partial \Phi}{\partial \xi}) + (\zeta - \xi) R_\eta \frac{\partial \Phi}{\partial \eta} (R_\eta \frac{\partial \Phi}{\partial \eta}) + (\xi - \eta) R_\zeta \frac{\partial \Phi}{\partial \zeta} (R_\zeta \frac{\partial \Phi}{\partial \zeta}) \right] = 0. \]

C. Charged Conducting Ellipsoid

The surface of the conducting ellipsoid is defined by \( \xi = 0 \). Thus, the electric field potential \( \Phi(\xi) \) is a function of \( \xi \) only, thereby defining the equipotential surfaces by confocal ellipsoids. Laplace’s equation is then simplified to

\[ \frac{d}{d\xi} \left( R_\xi \frac{d\Phi}{d\xi} \right) = 0. \]

The solution outside the ellipsoid is

\[ \Phi_{out}(\xi) = A \int_{\xi}^{\infty} \frac{d\xi'}{R_{\xi'}}. \]

From the asymptotic approximation \( \xi \approx r^2 \) for large distances \( r \to \infty \), i.e. \( \xi \to \infty \), we identify \( R_\xi \approx \xi^{3/2} \) and
Thus,
\[ \Phi_{\text{out}}(\xi \to \infty) \approx \frac{2A}{\sqrt{\xi}} = \frac{2A}{r}. \quad (85) \]

Using the boundary condition \( \lim_{\xi \to \infty} \Phi(\xi) = 0 \). Since the Coulomb field should be \( \Phi(\xi \to \infty) \approx \epsilon/r \) at large distances from the ellipsoid, \( 2A = \epsilon \) and
\[
\Phi_{\text{out}}(\xi) = \frac{\epsilon}{2} \int_\xi^\infty \frac{d\xi'}{R_{\xi'}}. \quad (86)
\]
is obtained, corresponding to the far-field of a monopole charge.

The solution inside the ellipsoid is
\[
\Phi_{\text{in}}(\xi) = B \int_{-c^2}^\xi \frac{d\xi'}{R_{\xi'}}. \quad (87)
\]
Using the asymptotic approximation \( R_{\xi \to -c^2} \propto \sqrt{\xi + c^2} \) we obtain
\[
\Phi_{\text{in}}(\xi \to -c^2) \approx B \sqrt{\xi + c^2}. \quad (88)
\]
This solution satisfies the boundary condition \( \lim_{\xi \to -c^2} \Phi(\xi) = 0 \). The constant \( B \) can be found from the boundary condition \( \Phi(\xi = 0) = V \), where \( V \) is the potential on the surface of the charged ellipsoid. Thus, \( B = V/c \) and
\[
\Phi_{\text{in}}(\xi) = \frac{V}{c} \sqrt{\xi + c^2}. \quad (89)
\]

**D. Dipole Moment of Conducting Ellipsoid induced by an External Electric Field in z-direction**

Following Ref. [30] let us consider the case when the external electric field is parallel to one of the major axes of the ellipsoid. For the external potential let us choose
\[
\Phi_0 = -E_0 z = -E_0 \sqrt{(\xi + c^2)(\eta + c^2)(\zeta + c^2)/(a^2 - c^2)(b^2 - c^2)}. \quad (90)
\]
Let \( \Phi_p \) be the potential caused by the ellipsoid, with the boundary condition \( \Phi_p(\xi \to \infty) = 0 \). Requiring continuous boundary condition on the surface of the ellipsoid, we have
\[
\Phi_{\text{in}}(0, \eta, \zeta) = \Phi_0(0, \eta, \zeta) + \Phi_p(0, \eta, \zeta). \quad (91)
\]
We make the ansatz
\[
\Phi_p(\xi, \eta, \zeta) = F_p(\xi) \sqrt{(\eta + c^2)(\zeta + c^2)}, \quad (92)
\]
which after insertion into the Laplace equation yields
\[
R_\xi \frac{d}{d\xi} \left[ R_\xi \frac{dF}{d\xi} \right] - \left( \frac{a^2 + b^2}{4} + \frac{\xi}{2} \right) F(\xi) = 0. \quad (93)
\]
Thus, one obtains for the field caused by the ellipsoid
\[
\Phi_p(\xi, \eta, \zeta) = C_p F_p(\xi) \sqrt{(\eta + c^2)(\zeta + c^2)}. \quad (94)
\]
with
\[
F_p(\xi) = F_{\text{in}}(\xi) \int_\xi^\infty \frac{d\xi'}{F_{\text{in}}(\xi') R_{\xi'}}, \quad (95)
\]
where
\[
F_{\text{in}}(\xi) = \sqrt{\xi + c^2}, \quad (96)
\]
the function we used in the case of the charged ellipsoid (see above). Thus, the field inside the ellipsoid is given by
\[
\Phi_{\text{in}} = C_{\text{in}} F_{\text{in}}(\xi) \sqrt{(\eta + c^2)(\zeta + c^2)}. \quad (97)
\]
Using the boundary condition shown in Eq. (91), one obtains the first equation
\[
C_p \int_0^\infty \frac{d\xi'}{(c^2 + \xi') R_{\xi'}} - C_{\text{in}} = \frac{E_0}{\sqrt{(a^2 - c^2)(b^2 - c^2)}}, \quad (98)
\]
The boundary condition of the normal component of \( \mathbf{D} \) at \( \xi = 0 \), equivalent to
\[
\varepsilon_m \frac{\partial \Phi_{\text{in}}}{\partial \xi} = \varepsilon_m \frac{\partial \Phi_0}{\partial \xi} + \varepsilon_m \frac{\partial \Phi_p}{\partial \xi}, \quad (99)
\]
yields the second equation
\[
\varepsilon_m C_p \left[ \int_0^\infty \frac{d\xi'}{(c^2 + \xi') R_{\xi'}} - \frac{2}{abc} \right] = \varepsilon_m C_{\text{in}} \frac{E_0}{\sqrt{(a^2 - c^2)(b^2 - c^2)}}, \quad (100)
\]
Consequently, the potentials are
\[
\Phi_{\text{in}} = \frac{\Phi_0}{1 + \frac{L_\lambda(\varepsilon_m - \varepsilon_m)}{\varepsilon_m}}, \quad (101)
\]
\[
\Phi_p = \Phi_0 \left[ \frac{abc}{2} \varepsilon_m - \varepsilon_m \right] \int_0^\infty \frac{d\xi'}{(c^2 + \xi') R_{\xi'}}, \quad (102)
\]
where
\[
L_\lambda = \frac{abc}{2} \int_0^\infty \frac{d\xi'}{(c^2 + \xi') R_{\xi'}}. \quad (103)
\]
Far away from the ellipsoid for \( \xi \approx r^2 \to \infty \), one can use the approximation
\[
\int_\xi^\infty \frac{d\xi'}{(c^2 + \xi') R_{\xi'}} \approx \int_\xi^{\xi/3} \frac{d\xi'}{\xi^{5/2}} = \frac{2}{3} \xi^{-3/2}. \quad (104)
\]
yielding the potential caused by the ellipsoid, i.e.

$$\Phi_p \approx \frac{E_0 \cos \theta}{r^2} \frac{abc}{4} \frac{\varepsilon_m - \varepsilon_m}{1 + \frac{L_3(\varepsilon_m - \varepsilon_m)}{\varepsilon_m}}, \quad (105)$$

from which we identify the dipole moment

$$p = p\hat{z} = 4\pi \varepsilon_m abc \frac{\varepsilon_m - \varepsilon_m}{3\varepsilon_m + 3L_3(\varepsilon_m - \varepsilon_m)} E_0 \hat{z}. \quad (106)$$

This result determines the polarizability of the charged ellipsoid, i.e.

$$\alpha_3 = 4\pi \varepsilon_m abc \frac{\varepsilon_m - \varepsilon_m}{3\varepsilon_m + 3L_3(\varepsilon_m - \varepsilon_m)}, \quad (107)$$

If the external electric field is applied along the other major axes of the ellipsoid, $x$ or $y$, the polarizabilities are

$$\alpha_1 = 4\pi \varepsilon_m abc \frac{\varepsilon_m - \varepsilon_m}{3\varepsilon_m + 3L_1(\varepsilon_m - \varepsilon_m)}, \quad (108)$$

$$\alpha_2 = 4\pi \varepsilon_m abc \frac{\varepsilon_m - \varepsilon_m}{3\varepsilon_m + 3L_2(\varepsilon_m - \varepsilon_m)}, \quad (109)$$

respectively, where

$$L_1 = \frac{abc}{2} \int_0^\infty \frac{d\xi'}{(a^2 + \xi')(b^2 + \xi')}, \quad (110)$$

$$L_2 = \frac{abc}{2} \int_0^\infty \frac{d\xi'}{(b^2 + \xi')(a^2 + \xi')} = \frac{2}{3}, \quad (111)$$

For oblate spheroids $(a = b)$, $L_1 = L_2$,

$$L_1 = \frac{g(e_o)}{2e_o^2} \left[ \pi - \arctan g(e_o) \right] - \frac{g^2(e_o)}{2}, \quad (112)$$

where $e_o$ is the eccentricity of the oblate spheroid. The limiting cases of an infinitesimally thin disk and a sphere are obtained for $\varepsilon_o = 1$ and $\varepsilon_o = 0$, respectively.

The geometrical factors $L_i$ are related to the depolarization factors $L_i$ by

$$E_{inx} = \frac{E_0 x - L_1 P_{inx}}, \quad (113)$$

$$E_{iny} = \frac{E_0 y - L_2 P_{iny}}, \quad (114)$$

$$E_{inz} = \frac{E_0 z - L_3 P_{inz}}, \quad (115)$$

with

$$L_i = \frac{\varepsilon_m - \varepsilon_m}{\varepsilon_m - \varepsilon_0}, \quad (116)$$

E. Dipole Moment of Conducting Ellipsoid induced by an External Electric Field in $x$-direction

In analogy to Ref. [30] let us consider the case when the external electric field is parallel to one of the major axes of the ellipsoid, in this case along the $x$-axis. For the external potential let us choose

$$\Phi_0 = -E_0 x = -E_0 \sqrt{\frac{(\xi + a^2)(\eta + a^2)(\zeta + a^2)}{(b^2 - a^2)(c^2 - a^2)}}. \quad (117)$$

Let $\Phi_p$ be the potential caused by the ellipsoid, with the boundary condition $\Phi_p(\xi \to \infty) = 0$. Requiring continuous boundary condition on the surface of the ellipsoid, we have

$$\Phi_{in}(0, \eta, \zeta) = \Phi_0(0, \eta, \zeta) + \Phi_p(0, \eta, \zeta). \quad (118)$$

Thus, one obtains for the field caused by the ellipsoid

$$\Phi_p(\xi, \eta, \zeta) = C_p F_p(\xi) \sqrt{(\eta + a^2)(\zeta + a^2)} \quad (119)$$

with

$$F_p(\xi) = \Phi_{in}(\xi) \int^\infty_\xi \frac{d\xi'}{F_{in}(\xi') R_{\xi'}}, \quad (120)$$

where

$$F_{in}(\xi) = \sqrt{\xi + a^2}, \quad (121)$$

the function we used in the case of the charged ellipsoid (see above). Thus, the field inside the ellipsoid is given by

$$\Phi_{in} = C_{in} F_{in}(\xi) \sqrt{(\eta + a^2)(\zeta + a^2)}. \quad (122)$$

Using the boundary condition shown in Eq. (118), one obtains the first equation

$$C_p \int_0^\infty \frac{d\xi'}{(a^2 + \xi')(b^2 + \xi')} - C_{in} = \frac{E_0}{\sqrt{(b^2 - a^2)(c^2 - a^2)}}. \quad (123)$$

The boundary condition of the normal component of $\mathbf{D}$ at $\xi = 0$, equivalent to

$$\varepsilon_m \frac{\partial \Phi_{in}}{\partial \xi} = \varepsilon_m \frac{\partial \Phi_0}{\partial \xi} + \varepsilon_m \frac{\partial \Phi_p}{\partial \xi}, \quad (124)$$

yields the second equation

$$\varepsilon_m C_p \left[ \int_0^\infty \frac{d\xi'}{(a^2 + \xi')(b^2 + \xi')} - \frac{2}{abc} \right] - \varepsilon_m C_{in}$$

$$= \frac{\varepsilon_m E_0}{\sqrt{(b^2 - a^2)(c^2 - a^2)}}. \quad (125)$$

Consequently, the potentials are

$$\Phi_{in} = \frac{\Phi_0}{1 + \frac{L_1(\varepsilon_m - \varepsilon_m)}{\varepsilon_m}}, \quad (126)$$

$$\Phi_p = \Phi_0 \frac{abc \varepsilon_m - \varepsilon_m}{2 \varepsilon_m} \int^\infty_\xi \frac{d\xi'}{(a^2 + \xi')(b^2 + \xi')} \frac{\xi}{\varepsilon_m} \frac{L_1(\varepsilon_m - \varepsilon_m)}{\varepsilon_m}, \quad (127)$$
where
\[ L_1 = \frac{abc}{2} \int_0^\infty \frac{d\xi'}{(a^2 + \xi')R_{\xi'}}. \] (128)

Far away from the ellipsoid for \( \xi \approx r^2 \to \infty \), one can use the approximation
\[ \int_\xi^\infty \frac{d\xi'}{(a^2 + \xi')R_{\xi'}} \approx \int_\xi^{\xi_0/2} \frac{d\xi'}{\xi'} = \frac{2}{3} \xi^{-3/2}, \] (129)
yielding the potential caused by the ellipsoid, i.e.
\[ \Phi_p \approx \frac{E_0 \cos \theta}{r^2} \frac{abc}{3} \frac{\varepsilon_m - \varepsilon_m}{\varepsilon_m - \varepsilon_m}, \] (130)
from which we identify the dipole moment
\[ p = p \hat{x} = 4\pi \varepsilon_m abc \frac{\varepsilon_m - \varepsilon_m}{3\varepsilon_m + 3L_1(\varepsilon_m - \varepsilon_m)} E_0 \hat{x}. \] (131)
This result determines the polarizability of the charged ellipsoid, i.e.
\[ \alpha_1 = \frac{4\pi \varepsilon_m abc}{3\varepsilon_m + 3L_1(\varepsilon_m - \varepsilon_m)} \] (132)

F. Dipole Moment of Conducting Single-sheet Hyperboloid with a Small Elliptical Wormhole induced by an External Electric Field

Contrary to the case of an uncharged ellipsoid, where the solutions when applying the external electric field in \( x, y \), or \( z \) direction are similar, the solutions in the case of an uncharged hyperboloid depend strongly on the axis in which the external field \( E_0 \) points. While the solutions for \( E_0 = E_0 \hat{x} \) and \( E_0 = E_0 \hat{y} \) are similar, the solution for \( E_0 = E_0 \hat{z} \) is completely different. The reason for this fundamental difference is that the ellipsoid resembles a sphere from far away. However, a single-sheet hyperboloid has elliptical cylindrical symmetry.

Here, let us first calculate the electrostatic potential \( \Phi(\xi, \eta, \zeta) \) of a conducting single-sheet hyperboloid with an elliptical hole, which can be represented by a limiting hyperboloid from a family of hyperboloids described by the implicit equation
\[ \frac{x^2}{a^2 + u} + \frac{y^2}{b^2 + u} + \frac{z^2}{c^2 + u} = 1 \] (133)
for \( a > b > c \). The cubic roots \( \xi, \eta, \zeta \) are all real in the ranges
\[ -a^2 \leq \xi \leq -b^2, \quad -b^2 \leq \eta \leq -c^2, \quad -c^2 \leq \zeta < \infty, \] (134)
which are the ellipsoid coordinates of a point \( (x,y,z) \). The limiting hyperboloid is a single planar sheet with an elliptical hole, i.e. it belongs to the family of solutions \( \eta \) in the limit \( \eta \to -c^2 \). Therefore, let us choose this limiting case as our origin in ellipsoidal coordinates with \( c = 0 \). Then Eq. (133) becomes
\[ \frac{x^2}{a^2 + u} + \frac{y^2}{b^2 + u} + \frac{z^2}{u} = 1 \] (135)
for \( a > b > c = 0 \). The cubic roots \( \xi, \eta, \zeta \) are all real in the ranges
\[ -a^2 \leq \xi \leq -b^2, \quad -b^2 \leq \eta \leq 0, \quad 0 \leq \zeta < \infty, \] (136)
The surface of the conducting hyperboloid is defined by \(-b^2 \leq \eta = \eta_1 < 0\).

Let us consider the case \( E_0 = E_0 \hat{x} \), which in the limit when the hyperboloid becomes a flat plane is the most relevant one. Therefore
\[ \Psi_0 = -E_0 x = \mp E_0 \sqrt{\frac{(\xi + a^2)(\eta + a^2)(\zeta + a^2)}{(b^2 - a^2)(-a^2)}} \] (137)
in the lower-half plane, where the negative sign corresponds to positive \( x \) values and the positive sign to negative \( x \) values. Since the equipotential surfaces are determined by \( \eta \), let \( \Psi_p \) be the potential caused by the hyperboloid, with the boundary condition \( \Psi_{in}(\eta = 0) = 0 \). Requiring continuous boundary condition on the surface of the hyperboloid, we have
\[ \Psi_{in}(\xi, \eta, \zeta) = \Psi_0(\xi, \eta, \zeta) + \Psi_p(\xi, \eta, \zeta), \] (138)
\[ \varepsilon_m \frac{\partial \Psi_{in}}{\partial \eta} \bigg|_{\eta} = \varepsilon_m \frac{\partial \Psi_p}{\partial \eta} \bigg|_{\eta}, \] (139)
where in the second equation the normal component of \( \mathbf{D} \) at \( \eta = \eta_1 \) must be continuous. Then we make the ansatz for the electrostatic potential inside the hyperboloid,
\[ \Psi_{in}(\xi, \eta, \zeta) = -C \left. E_0 x \right|_{\eta}, \] (140)
where $C_{in}$ is a constant. This ansatz satisfies the boundary condition $\Psi_{in}(\xi = 0, \eta \to 0, \zeta) = 0$. For the outside polarization field we choose
\[
\Psi_p(\xi, \eta, \zeta) = -C_p E_0 x F_1(\xi) K_1(\eta) \tag{141}
\]
where $C_p$ is a constant, and we defined
\[
F_1(\xi) = \int_\xi^{\infty} \frac{ad\xi'}{2\xi'^{1/2}(\xi' + a^2)} - \int_\xi^{\infty} \frac{ad\xi'}{2(\xi' + a^2)^{3/2}} = \arctan\left(\frac{a}{\sqrt{\xi + a^2}}\right) - \frac{a}{\sqrt{\xi + a^2}} \tag{142}
\]
Note that $\lim_{\xi \to 0^+} \arctan\left(\frac{a}{\sqrt{\xi}}\right) = \pi/2$, whereas $\lim_{\xi \to 0^-} \arctan\left(\frac{a}{\sqrt{\xi}}\right) = -\pi/2$. Therefore, in order to avoid discontinuity at $\xi = 0$, we must have
\[
K_1(\eta) = \int_\eta^{\infty} \frac{dy'}{(y' + a^2)R_{\eta}^{y'}} \tag{143}
\]
where $R_{\eta} = \sqrt{(\eta + a^2)(\eta + b^2)(-\eta)}$. The boundary conditions at $z \to \pm \infty$ are satisfied:
\[
F_1(\xi) = \begin{cases} 
0 & \text{for } z \to +\infty \\
\pi & \text{for } z \to -\infty.
\end{cases} \tag{144}
\]
At large distances $r = \sqrt{x^2 + y^2 + z^2}$ from the wormhole we have $\xi \approx r^2$. Then the far-field potential in the upper half-space, which is given by the pure polarization field, is
\[
\Psi_p(\xi, \eta, \zeta) \approx -C_p E_0 x K_1(\eta) \approx -b^2 \frac{1}{3} \left(\frac{a}{\sqrt{\xi}}\right)^3 \tag{145}
\]
The polarization far-field has the form of a dipole field at large distances $r$ from the wormhole.

In order to determine the polarizability of the wormhole, let us find the solution at $\xi = 0$, corresponding to the plane that passes through the center of the wormhole. For $\xi = 0$, the unit vectors $\hat{\xi}$ and $\hat{\eta}$ are parallel. In this near-field limit, the polarization potential has the form
\[
\Psi_p(\xi, \eta, \zeta) = -\hat{C}_p E_0 x K_1(\eta), \tag{146}
\]
where $\hat{C}_p = C_p (\pi/2 - 1)$.

Using the boundary conditions shown in Eq. (139), we obtain the first equation
\[
\hat{C}_p K_1(\eta_1) - C_{in} = 1, \tag{147}
\]
and the second equation
\[
\varepsilon_m \hat{C}_p \left[ K_1(\eta_1) \frac{\partial x}{\partial \eta} \bigg|_{\eta_1} + K_1'(\eta_1) \left. x \right|_{\eta_1} \right] - \varepsilon_{in} C_{in} \frac{\partial x}{\partial \eta} \bigg|_{\eta_1} = \varepsilon_m \frac{\partial x}{\partial \eta} \bigg|_{\eta_1}. \tag{148}
\]
Using the derivatives
\[
\left. \frac{\partial x}{\partial \eta} \right|_{\xi=0,\eta_1} = \frac{a}{2} \sqrt{\frac{\zeta + a^2}{(\eta_1 + a^2)(\eta_1 + b^2)(\eta_1 - c^2)}}, \tag{149}
\]
\[
K_1'(\eta_1) = \frac{1}{(\eta_1 + a^2)R_{\eta_1}}, \tag{150}
\]
we can rewrite the second equation as
\[
\varepsilon_m \hat{C}_p \left[ K_1(\eta_1) \frac{\partial x}{\partial \eta} \bigg|_{\eta_1} + K_1'(\eta_1) \left. x \right|_{\eta_1} \right] - \varepsilon_{in} C_{in} \frac{1}{\eta_1 + a^2} = \varepsilon_m \frac{1}{\eta_1 + a^2}, \tag{151}
\]
which is equivalent to
\[
\varepsilon_m \hat{C}_p \left[ K_1(\eta_1) \frac{1}{\eta_1 + a^2} \right] - \varepsilon_{in} C_{in} = \varepsilon_m. \tag{152}
\]
Thus, the potentials are
\[
\Psi_{in} = \frac{\Psi_0}{1 + \frac{L_1(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}}, \tag{153}
\]
\[
\Psi_p = \frac{R_{\eta_1} \frac{\varepsilon_{in} - \varepsilon_m}{\varepsilon_m} F_1(\xi) K_1(\eta)(\pi/2 - 1)}{1 + \frac{L_1(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}}. \tag{154}
\]
Then the far-field potential in the upper half-space, which is given by the pure polarization field, is
\[
\Psi_p \approx -E_0 \frac{R_{\eta_1} \frac{\varepsilon_{in} - \varepsilon_m}{\varepsilon_m} K_1(\eta) \approx -b^2(\pi/2 - 1) a^3 x}{1 + \frac{L_1(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}} \tag{155}
\]
\[
\approx -E_0 \frac{ab\sqrt{-\eta_1} \frac{\varepsilon_{in} - \varepsilon_m}{\varepsilon_m} a^3 x}{1 + \frac{L_1(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}} \tag{156}
\]
\[
= -E_0 \frac{ab\sqrt{-\eta_1} \frac{\varepsilon_{in} - \varepsilon_m}{\varepsilon_m} \pi(\pi/2 - 1) 2x}{1 + \frac{L_1(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}} \tag{157}
\]
where we assumed that $a \approx b$. The polarization far-field has the form of a dipole field at large distances $r$ from the wormhole. If the external electric field is applied in $y$-direction, we obtain the potentials
\[
\Psi_{in} = \frac{\Psi_0}{1 + \frac{L_2(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}}, \tag{156}
\]
\[
\Psi_p = \frac{R_{\eta_1} \frac{\varepsilon_{in} - \varepsilon_m}{\varepsilon_m} F_2(\xi) K_2(\eta)(\pi - 1)}{1 + \frac{L_2(\varepsilon_{in} - \varepsilon_m)}{\varepsilon_m}}, \tag{157}
\]
with
\[
F_2(\xi) = \frac{bd\xi'}{2\xi'^{1/2}(\xi' + b^2)} - \frac{bd\xi'}{2(\xi' + b^2)^{3/2}}, \tag{158}
\]
\[
K_2(\eta) = \int_\eta^{\infty} \frac{dy'}{(y' + b^2)R_{\eta'}^{y'}}. \tag{159}
\]
We defined the geometrical factors

\[ L_1 = R_{\eta_1} K_1(\eta_1) \approx ab\sqrt{-\eta_1} \int_{\eta_1}^{\infty} \frac{dy'}{(y'^2 + a^2)R_{y'}} \]  
\[ L_2 = R_{\eta_1} K_2(\eta_1) \approx ab\sqrt{-\eta_1} \int_{\eta_1}^{\infty} \frac{dy'}{(y'^2 + b^2)R_{y'}} \]

which are related to the depolarization factors by

\[ \tilde{L}_i = \frac{\varepsilon_{\text{in}} - \varepsilon_m}{\varepsilon_{\text{in}} - \varepsilon_0} \frac{L_i}{L_i} \]

This result determines the polarizability of the uncharged hyperboloid observable in the far-field, i.e.

\[ \alpha_1 = \frac{2ab\sqrt{-\eta_1}\pi(\pi/2 - 1)}{3} \frac{\varepsilon_{\text{in}} - \varepsilon_m}{\varepsilon_m + L_1(\varepsilon_{\text{in}} - \varepsilon_m)} \]

Similarly, we obtain the polarizability in y-direction, i.e.

\[ \alpha_2 = \frac{2ab\sqrt{-\eta_1}\pi(\pi/2 - 1)}{3} \frac{\varepsilon_{\text{in}} - \varepsilon_m}{\varepsilon_m + L_2(\varepsilon_{\text{in}} - \varepsilon_m)} \]

Comparing to the polarizabilities of ellipsoids the polarizabilities of hyperboloids are proportional to \(ab\sqrt{-\eta_1}\), which corresponds to the volume of the ellipsoid \(abc\).

In the case of circular wormholes, we have \(a = b\), and therefore \(\alpha_1 = \alpha_2 = \alpha_{||}\), with \(L_1 = L_2 = L_{||}\).

G. Dispersion relations

In our proposed mid-IR light source the effective combination of Si\(_3\)N\(_4\) and h-BN behaves as an environment with polar phonons. Polar materials have ions of different valence, whose oscillating dipole moment gives rise to the interaction between electrons and optical phonons, the Frohlich interaction. By placing graphene on a polar substrate the long range Frohlich interaction mediates the interaction between optical phonons and surface plasmons in graphene. The interaction between polar substrate/graphene phonons and electrons in graphene modifies substantially the graphene plasmon dispersion relation, which is shown in Fig. 18. The dielectric function of graphene in the random phase approximation (RPA) takes the form

\[ \varepsilon^{RPA}(q, \omega) = \varepsilon_m - v_{\text{e}}(q)\chi_0^0(q, \omega) - \varepsilon_m \sum_i v_{\text{sph},i}(q, \omega)\chi_0^0(q, \omega) - \varepsilon_m v_{\text{ph}}(q, \omega)\chi_{0,0}^0(q, \omega) \]

(165)

The second term represents the effective Coulomb interaction of electrons in graphene, and \(v_{\text{e}}(q) = e^2/2\varepsilon_0 q\) is the direct Coulomb interaction. The third term is the effective dielectric function for different phonon modes \(i\) coming from electron-electron interaction mediated by substrate optical phonons, which couple to the electrons by means of the Frohlich interaction, i.e.

\[ v_{\text{sph},i}(q, \omega) = |M_{\text{sph}}|G_0^0(\omega) \]

(166)

where \(|M_{\text{sph}}|^2\) is the scattering and \(G_0^0(\omega)\) is the free phonon Green function. The last term of Eq. (165) corresponds to the optical phonon mediated electron-electron interaction

\[ v_{\text{ph}}(q, \omega) = |M_{\text{ph}}|^2G_0^0(\omega) \]

(167)

Here \(|M_{\text{ph}}|^2\) defines the scattering matrix element and \(G_0^0(\omega)\) is the free phonon Green function. In Eq. (165), \(\chi_{0,0}^0(q, \omega)\) is the current-current correlation function. This description is very general and can be applied to any metallic system.

The momentum relaxation time \(\tau\) can be derived by considering the impurity, electron-phonon interaction, and the scattering related to nanostructure edges \(\tau^{-1} = \tau_{\text{DC}}^{-1} + \tau_{\text{edge}}^{-1} + \tau_{\text{e-p}}^{-1}\), which determines the plasmon lifetime and the absorption spectrum bandwidth. It can be evaluated via the measured DC mobility \(\mu\) of the graphene sample through \(\tau_{\text{DC}} = \mu h/\varepsilon_F^0 ev_F\), where \(v_F = 10^6\) m/s is the Fermi velocity and \(\tau_{\text{DC}} = \mu h/\varepsilon_F^0 ev_F\) is the charge carrier density. \(\tau_{\text{edge}} \approx (1 \times 10^6 \text{m/s}/w - w_0)^{-1}\) is due to the scattering from the nanostructure edges, where \(w\) is the edge-to-edge distance of the holes and \(w_0 = 7\) nm is the parameter that includes edge effects, and \(\tau_{\text{e-p}} = h/2\text{Im}(\sum_{\text{e-ph}})\) is related to the scattering because of coupling of electrons and phonons. The imaginary part of the electron-phonon self-energy is given by

\[ \text{Im}\left(\sum_{\text{e-ph}}\right) = \gamma |h\omega - \text{sgn}(h\omega - E_F)| h\omega_{\text{ph}} \]

(168)
\[ \gamma = 18.3 \times 10^{-3} \] is a dimensionless constant describing the electron-phonon coupling coefficient, and \( \hbar \omega_{\text{ph}} \approx 0.2 \) eV is the graphene optical phonon energy. It is evident that the plasmon lifetime is reduced due to electron-phonon interaction and edge scattering, but the DC conductivity, which is used to calculate the dielectric function of graphene, is invariant if the edge-to-edge distance of the pattern is larger than the carrier mean free path \( L_{\text{MFP}} = v_F T_{\text{DC}} \).

The Drude model and the optical phonon frequency are not valid for a patterned graphene sheet only if the edge-to-edge distance is much lower than the carrier mean free paths of electrons and phonons. For the current pattern and carrier mobilities, both the mean free paths \( L_e \) and \( L_{\text{ph}} \) are smaller than or of the same order as the edge-to-edge distance, which means that we can safely assume that the Drude model and optical phonon frequencies of our patterned graphene sheet are the same as for pristine graphene. The coupling of plasmon and substrate graphene phonon can be characterized through the loss function \( Z \), which is the imaginary part of inverse effective dielectric function calculated via the generalized RPA theory

\[ Z \propto -\text{Im} \left( \frac{1}{\varepsilon_{\text{RPA}}} \right). \quad \text{(169)} \]

The loss function represents the amount of energy dissipated by exciting the plasmon coupled to the substrate and optical phonons in graphene. The surface plasmons in graphene are damped through radiative and nonradiative processes. Nonradiative damping transfers the plasmon energy to hot electron-hole excitation by means of intraband transition. Fig. 13(a) shows the loss function for graphene with carrier mobility \( \mu = 3000 \text{ cm}^2/\text{V.s} \) and a Fermi energy of \( \epsilon_F = 1.0 \) eV. The thickness of the optical cavity is chosen to be \( \lambda/4n \), where \( n \) is the refractive index of the cavity material. The plasma assisted electron-hole pair generation in this structure lies outside the Landau intraband damping region, indicated by the shaded area in Fig. 13(a). A band gap in the plasmon-phonon dispersion relation is formed via Frohlich interaction between graphene plasmons and optical phonons. This coupling leads to the splitting of the energy into two distinct branches: surface plasmon phonon polaritons (SPPPs) and graphene plasmons (GPs). The horizontal branch line marked as \( \omega_{\text{LSP}} \) is the LSP mode and is independent of the plasmon wavevector due to the localization of the LSP around a hole. The resonance frequencies of the polar phonons are denoted by \( \omega_{\text{BN}} \) for h-BN and by \( \omega_{\text{SN}} \) for Si\(_3\)N\(_4\).

**H. Integral of dyadic Green function elements over spherical angle**

For the calculation of the spectral radiance we need to integrate the elements of the dyadic Green function over the spherical angle. We can split the total dyadic Green function into a free space term \( \vec{G}_0(r, r'; \omega) \) and a term \( \vec{G}_{\text{SPP}}(r, r'; \omega) \) that creates surface plasmon polaritons inside graphene. Since the absorbance of the pristine graphene sheet is only 2.3%, we can safely neglect \( \vec{G}_{\text{SPP}}(r, r'; \omega) \). Our goal is to calculate the gray-body emission of the EM radiation from the LSP around the holes in graphene into free space. Therefore, we need to evaluate

\[ I_{\text{GB}}^S(\omega) = \lim_{r \to \infty} r^2 \sin \theta d\theta d\varphi |I_{\text{GB}}(r, \omega)|, \quad \text{(170)} \]

where can use the approximation

\[ I_{\text{GB}}(r, \omega) = I_0(r, \omega) - I_{\text{SPP}}(r, \omega) \approx I_0(r, \omega). \quad \text{(171)} \]

In Cartesian coordinates, we can write down the dyadic Green function as

\[ \vec{G}_0(\omega) = \frac{e^{ikr}}{4\pi r} \left[ \left( 1 + i \frac{k}{r} - \frac{1}{k^2 r^2} \right) \right] \]

\[ \vec{G}_{\text{SPP}}(\omega) = \frac{e^{ikr}}{4\pi r} \left[ \left( -i \sin \theta \cos \varphi \right) \right] \]

Since we are interested only in the far field, we consider only the far-field component of the dyadic Green function, which is

\[ \vec{G}_{\text{FF}}(\omega) = \frac{e^{ikr}}{4\pi r} \left[ \left( \sin \theta \cos \varphi \right) \right] \]

which possesses only angular (transverse) components but no radial (longitudinal) components. Then the necessary components are

\[ G_{xx}(r, \omega) = \frac{e^{ikr}}{4\pi r} \left[ -2 \sin^2 \theta \cos^2 \varphi \right] \]

\[ G_{yx}(r, \omega) = \frac{e^{ikr}}{4\pi r} \left[ -2 \sin \theta \cos \varphi \sin \varphi \right] \]

\[ G_{xy}(r, \omega) = \frac{e^{ikr}}{4\pi r} \left[ -2 \sin \theta \cos \varphi \sin \varphi \right] \]

\[ G_{yy}(r, \omega) = \frac{e^{ikr}}{4\pi r} \left[ -2 \cos^2 \varphi \right] \]

\[ G_{zy}(r, \omega) = \frac{e^{ikr}}{4\pi r} \left[ -2 \sin \theta \cos \varphi \sin \varphi \right] \]

The corresponding integrals are

\[ \int r^2 \sin \theta d\theta d\varphi \left| G_{xx}(r, \omega) \right|^2 = \frac{2}{15\pi}, \]

\[ \int r^2 \sin \theta d\theta d\varphi \left| G_{yx}(r, \omega) \right|^2 = \frac{4}{15\pi}, \]

\[ \int r^2 \sin \theta d\theta d\varphi \left| G_{xy}(r, \omega) \right|^2 = \frac{4}{15\pi}, \]

\[ \int r^2 \sin \theta d\theta d\varphi \left| G_{yy}(r, \omega) \right|^2 = \frac{2}{15\pi}, \]

\[ \int r^2 \sin \theta d\theta d\varphi \left| G_{zy}(r, \omega) \right|^2 = \frac{4}{15\pi}. \quad \text{(175)} \]
