Prevalence of Irritable Bowel Syndrome to Kimpesse, A Rural Urban City in Democratic Republic of Congo (DRC)

Abstract

Background: Irritable bowel syndrome (IBS) is the most common functional gastrointestinal disorder.

Aim: Determine the prevalence and the symptoms patterns of IBS in the rural urban community setting in DRC.

Materials and Methods: Questionnaires were administered to consenting individuals. Subjects satisfying the Rome III criteria of IBS were included.

Results: Out of 476 individuals, 28 adults had IBS (5.8%). There were 14 males (50%) and 14 females (50%). The mean age was 31.4 years (18-67 years). 50% of them had IBS-C, 28.5% had IBS-D and 14.2% had IBS. The majority of IBS (+) 50% were in age group 18-27 years old. IBS (+) were highest in married group 57.1%. The majority of IBS (+) 75% had only one meal per day. There were 71.4% taking vegetables three times per week, 78.6 drinking only one glass of water daily, 25% smokers, 57.1% taking alcohol and 71.4% with spicy consumption. 50% of participants had 6 consultations through 6 months.

Conclusion: IBS is prevalent, the stress play a role to make up this disorder. The subtype C is more observed. Young adults are highly affected. IBS carry away medical consumption.

Keywords: Irritable bowel syndrome; Epidemiology

Introduction

Irritable bowel syndrome (IBS) is the most common functional gastrointestinal disorder with a worldwide prevalence ranging 7%-21% [1]. The diagnosis of IBS does not require diagnostic testing unless needed to exclude other diagnostic possibilities. IBS is characterized by presence of abdominal pain or discomfort associated with altered bowel habits. Although the Rome IV criteria already described, Rome III criteria that assess the relationship between abdominal pain or discomfort, stool form and change in bowel frequency are the most accepted criteria used in clinical practice for making a clinical diagnosis. Three clinical types have been recognized based on altered bowel motility and the resulting predominant feature: constipation predominant (C-IBS), diarrhea predominant (IBS-D) and IBS with mixed features of both diarrhea as well as constipation (M-IBS) [2]. Women are at a slightly higher risk of IBS than men [1]. Approximately two-thirds of IBS patients are female [3]. IBS is most prevalent in patients 20 to 30 years old and decreases with age [1]. In our country, Shindano at al carry out a study that reveal a prevalence of IBS ranged to 22.5% in urban area [4]. The aim of this study was to determine the prevalence and the symptoms patterns of IBS in the rural urban community setting in DRC.

Materials and Methods

Questionnaires were administered to consenting individuals. Subsets satisfying the Rome III criteria of IBS were included. The questionnaire was divided into three parts: The first part was designed to investigate individuals′ socio-economic demographic data and patient characteristics as age, sex, marital status, education, occupation, number of regular meals per day, fiber consumption, spicy intake, daily water consumption, coffee consumption, alcohol consumption, smoking, direct costs (number of consultation per 6 months).

Ethical Considerations

Aim of the research was explained to the participants. Informed consent from the participants was taken before starting the interview. The study was approved by the ethics committee of faculty of medicine, Kongo University (DRC) and has been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki.

Results

Out of 476 individuals, 28 adults had IBS (5.8%). There were 14 males (50%) and 14 females (50%). The mean age was 31.4 years (18-67 years). 50% of them had IBS-C, 28.5% had IBS-D and 14.2% had IBS. The majority of IBS (+) 50% were in age group 18-27 years old. IBS (+) were highest in married group 57.1% (Table 1). The majority of IBS (+) 75% had only one meal per day. There were 71.4% taking vegetables three times per week, 78.6 drinking only one glass of water daily, 25% smokers, 57.1% taking alcohol and 71.4% with spicy consumption. 50% of participants had 6 consultations through 6 months.
of water daily, 25 % smokers, 57.1 % taking alcohol and 71.4 % with spicy consumption (Table 5). 50% of participants had 6 consultations through 6 months (Table 6).

Table 1: Sub types of IBS.

| Sub Types      | N=28 | %  |
|----------------|------|----|
| IBS-C          | 14   | 50 |
| IBS-D          | 8    | 28.57 |
| IBS-M          | 4    | 14.29 |
| Unspecified IBS| 2    | 7.14 |
| Total          | 28   | 100 |

Table 2: Age groups.

| Age Groups | N=28 | %  |
|------------|------|----|
| 12-27      | 14   | 50 |
| 28-37      | 7    | 25 |
| 38-47      | 4    | 14.2 |
| 48-57      | 2    | 7.14 |
| Over 57    | 1    | 3.57 |
| Total      | 28   | 100 |

Table 3: Matrimonial status.

| Status        | N=28 | %  |
|---------------|------|----|
| Married       | 18   | 57.14 |
| Single        | 8    | 28.57 |
| Divorcee      | 3    | 10.72 |
| Widower       | 1    | 3.57 |
| Total         | 28   | 100 |

Table 4: Meal number per day.

| Number | N=28 | %  |
|--------|------|----|
| 1      | 21   | 7.5 |
| 2      | 5    | 17.86 |
| 3      | 2    | 7.14 |
| More than 4 | 0 | 0 |
| Total  | 28   | 100 |

Table 5: Eating habits.

| Alimony          | N=28 | %  |
|------------------|------|----|
| Cassava Flour    |      |    |
| -twice/week      | 2    | 7.14 |
| -four time/week  | 25   | 89.29 |
| -none time/week  | 1    | 3.57 |
| Vegetables       |      |    |

Table 6: Number of medical consultations per year.

| Number | N=28 | %  |
|--------|------|----|
| 1-3    | 4    | 14.29 |
| 4-6    | 10   | 35.72 |
| 6      | 14   | 50 |
| Total  | 28   | 100 |

Discussion

In the present study, IBS prevalence of 5.8% was found. This prevalence is different from other studies. Another Congolese sample reported a prevalence of 22.5% using Rome III in an urban area [4]. Lovell et al range the worldwide prevalence between 7%
The prevalence of IBS is significantly more common among women than men. Drossman reported that two-thirds of IBS patients are female [3]. Ntagirabiri in Burundi observed that the prevalence of IBS is high in female than male and the difference was statically significant [8]. Our study found no difference between men and female. The sample was small. It can explain this finding. Food intolerance has been proposed as a potential cause of GI symptoms in some patients with IBS; however, this link is not well established. Although some patients associate onset of IBS symptoms with ingestion of particular foods, the relationship between IBS and eating regular meals per day, insufficient fiber in the diet, daily water consumption, smoking or alcohol consumption is typically time-consuming and difficult to implement [9]. The present study did not analyze the relationship between IBS and eating regular meals per day, insufficient fiber in the diet, daily water consumption, smoking or alcohol consumption. Nevertheless, the predominant of subtype C can be explained by the low number of regular meals, the low daily water consumption.

**Conclusion**

IBS is prevalent, the stress play a role to make up this disorder. The subtype C is more observed. Young adults are highly affected.

IBS carry away medical consumption. The results of the current study are important for directing our attention towards improving the quality of life of IBS patients in addition to symptomatic treatment.
