The Relation between KMS States for Different Temperatures

Christian D. Jäkel

August 2003

Abstract

Given a thermal field theory for some temperature $\beta^{-1}$, we construct the theory at an arbitrary temperature $1/\beta'$. Our work is based on a construction invented by Buchholz and Junglas, which we adapt to thermal field theories. In a first step we construct states which closely resemble KMS states for the new temperature in a local region $O_0 \subset \mathbb{R}^4$, but coincide with the given KMS state in the space-like complement of a slightly larger region $\hat{O}$. By a weak*-compactness argument there always exists a convergent subnet of states as the size of $O_0$ and $\hat{O}$ tends towards $\mathbb{R}^4$. Whether or not such a limit state is a global KMS state for the new temperature, depends on the surface energy contained in the layer in between the boundaries of $O_0$ and $\hat{O}$. We show that this surface energy can be controlled by a generalized cluster condition.

1 Introduction

A quantum field theory can be specified by a $C^*$-algebra $\mathcal{A}$ together with a net

$$\mathcal{O} \to \mathcal{A}(\mathcal{O}), \quad \mathcal{O} \subset \mathbb{R}^4,$$

of subalgebras associated with open, bounded space-time regions $\mathcal{O}$ in Minkowski space (as described in the monograph by Haag [H]; see also [HK]). The Hermitian elements of $\mathcal{A}(\mathcal{O})$ are interpreted as the observables which can be measured at times and locations in $\mathcal{O}$. Technically the algebra $\mathcal{A}(\mathcal{O})$ may be thought of as being generated by bounded functions of the underlying smeared quantum fields (see, e.g., [BoY]). For instance, if $\phi(x)$ is a hermitian quantum field and if $f(x)$ is a real test function with support in a bounded region $\mathcal{O}$ of space-time, then the unitary operator $a := \exp(i \int dx f(x) \phi(x))$ is a typical element of $\mathcal{A}(\mathcal{O})$. In this way the quantum fields provide a “coordinate system” for the algebra $\mathcal{A}$. However, as emphasized by Haag and Kastler, only the algebraic relations between the elements of $\mathcal{A}$ are of physical significance.

If the time evolution is given by a strongly continuous one-parameter group of automorphisms $\{\tau_t\}_{t \in \mathbb{R}}$ of $\mathcal{A}$, then the pair $(\mathcal{A}, \tau)$ forms a $C^*$-dynamical system. Such a description of a QFT fits nicely into the structure of algebraic quantum statistical mechanics (see, e.g., [BR][E][R][Se][Th]) and we can therefore rely on this well-developed framework.

Up till now non-relativistic quantum field theories and spin systems were favoured in the framework of algebraic quantum statistical mechanics. In low dimensions the latter have been worked out in great detail (see, e.g., [BR]). Only recently the benefits of formulating thermal field theory in the algebraic framework were emphasized in a series of papers [BJu 86][BJu 89][BB 94][N][J¨a 98][J¨a 99][J¨a 04].

Equilibrium states can be characterized by first principles in the algebraic framework: equilibrium states are invariant under the time-evolution and stable against small dynamical (or adiabatic [NT]) perturbations of the time-evolution [HKTP]. Adding a few technical assumptions such a heuristical characterization of an equilibrium state leads to a sharp mathematical criterion [HHW], named for Kubo [K], Martin and Schwinger [MS]:

**Definition.** A state $\omega_{\beta}$ over $\mathcal{A}$ is called a $(\tau, \beta)$-KMS state for some $\beta \in \mathbb{R} \cup \{\pm \infty\}$, if

\[
\omega_{\beta}(a \tau_{\beta}(b)) = \omega_{\beta}(ba)
\]

for all $a, b$ in a norm dense, $\tau$-invariant $*$-subalgebra of $\mathcal{A}_\tau$. Here $\mathcal{A}_\tau \subset \mathcal{A}$ denotes the set of analytic elements for $\tau$.

We note that there are $C^*$-dynamical systems $(\mathcal{A}, \tau)$, for which a KMS state exists at one and only one value $\beta \in \mathbb{R}$ (see [BR] 5.3.27). But for a QFT on can specify conditions on the phase-space properties in the vacuum representation, such that KMS states exist for all temperatures $\beta^{-1} > 0$ [BJu 89]. These conditions exclude (see [BJu 86]) the class of models with a countable number of free scalar particles proposed by Hagedorn [Ha]. These models obey all the Wightman and Haag-Kastler axioms but they do not allow equilibrium states above a certain critical temperature.

For a generic model one expects that for high temperatures and low densities the set of KMS states contains a unique element\(^1\), whereas at low temperature it should contain many disjoint extremal KMS states and their convex combinations corresponding to various thermodynamic phases and their possible mixtures. The symmetry, or lack of symmetry of the extremal KMS states is automatically determined by this decomposition. Consequently, spontaneous symmetry breaking may occur, when we change the temperature in the sequel.

\(^1\)For non-relativistic fermions with pair-interaction see [J¨a 95].
Given a KMS state $\omega_\beta$ over $\mathcal{A}$ the GNS-representation $(\pi_\beta, \mathcal{H}_\beta, \Omega_\beta)$ provides a net of von Neumann algebras:

$$\mathcal{O} \to \mathcal{R}_\beta(\mathcal{O}) := \pi_\beta(\mathcal{A}(\mathcal{O}))'', \quad \mathcal{O} \in \mathbb{R}^4.$$ 

Under fairly general circumstances KMS states for different values of the temperature $\beta^{-1}$ lead to unitarily inequivalent GNS-representations (see [BR, 5.3.35]). Hence thermal field theories for different temperatures are frequently treated as completely disjoint objects even if they refer to the same vacuum theory, i.e., even if they show identical interactions on the microscopic level. To understand the relations between these ‘disjoint thermal field theories’ seems to be highly desirable.

One simple case is well known ([Pe, 8.12.10]): Assume that the time-evolution $\tau$ can be approximated by a net of inner automorphisms such that, for $a \in \mathcal{A}$ fixed,

$$\lim_{\Lambda \to \infty} \| \tau_z(a) - e^{izh_\Lambda}ae^{-izh_\Lambda} \| = 0, \quad h_\Lambda = h_\Lambda^* \in \mathcal{A},$$

uniformly in $z$ on compact subsets of $\mathcal{C}$. If $(\mathcal{A}, \tau)$ has a KMS state $\omega_\beta$ at some $\beta \neq 0$, then the net of states $\Lambda \mapsto \omega_\Lambda$,

$$\omega_\Lambda(a) = \frac{\omega_\beta(e^{\frac{1}{2}(\beta-\beta')h_\Lambda}ae^{\frac{1}{2}(\beta-\beta')h_\Lambda})}{\omega_\beta(e^{(\beta-\beta')h_\Lambda})}, \quad a \in \mathcal{A},$$

has convergent subnets and the limit points $\omega_{\beta'} := \lim_\Lambda \omega_\Lambda$ are $(\tau, \beta')$-KMS states for the new temperature $1/\beta'$ ($0 < \beta' < \infty$).

But in general, phase transitions may occur while we change the temperature. Consequently “… there is no simple prescription for connecting the $(\tau, \beta)$–KMS states for different $\beta$‘s” (c.f. [BR] p.78). Nevertheless, we will provide a prescription which covers, as far as relativistic systems are concerned, the physically relevant cases.

We start from a thermal field theory $\mathcal{O} \to \mathcal{R}_\beta(\mathcal{O})$, whose number of local degrees of freedom is restricted in a physically sensible manner. Using a method, which is essentially due to Buchholz and Junglas [BJu 89], we construct a KMS state $\omega_{\beta'}$ and a thermal field theory

$$\mathcal{O} \to \mathcal{R}_{\beta'}(\mathcal{O}), \quad \beta' \in \mathbb{R}^+, \quad \beta' > 0,$$

for a new temperature $1/\beta' > 0$. Although we almost repeat their line of arguments, there are some nontrivial deviations due to the mathematical structure we encounter in thermal field theory.

In a first step we construct product states $\omega_\Lambda, \Lambda = (\mathcal{O}_o, \hat{\mathcal{O}})$, which—up to boundary effects—resemble KMS states for the new temperature $1/\beta'$ in a local region $\mathcal{O}_o \subset \mathbb{R}^4$, but coincide with the given KMS state $\omega_\beta$ in the space-like complement of a slightly larger region $\hat{\mathcal{O}}$:

$$\omega_\Lambda(ab) = \omega_\Lambda(a) \cdot \omega_\beta(b) \quad \forall a \in \mathcal{A}(\mathcal{O}_o), \quad \forall b \in \mathcal{A}(\hat{\mathcal{O}}').$$

At this point our method is semi-constructive; the product states $\omega_\Lambda$ is not uniquely fixed. Intuitively the choice of a particular product state $\omega_\Lambda$ corresponds to a choice of the boundary conditions which decouple the local region $\mathcal{O}_o$, where the state already resembles an equilibrium state for the new temperature, from the space-like complement of $\hat{\mathcal{O}}$. Different choices $\omega_\Lambda, \omega_\Lambda'$ should manifest themselves in different expectation values for observables localized in between the two regions $\mathcal{O}_o$ and $\mathcal{O}'$. I.e., we expect

$$\omega_\Lambda \neq \omega_\Lambda' \Rightarrow \exists a \in \mathcal{A}(\mathcal{O}_o' \cap \hat{\mathcal{O}}) \text{ such that } \omega_\Lambda(a) \neq \omega_\Lambda'(a).$$

It follows from standard compactness arguments that the net of states $\Lambda \mapsto \omega_\Lambda$ has convergent subnets. Whether or not these subnets converge to a global KMS states for the new temperature depends on the surface energy contained in between the two regions $\mathcal{O}_o$.
and \( \hat{O}' \) as their size increases. Introducing an auxiliary structure, which can be understood as a local purification, and assuming a cluster condition, we will control these surface energies in all thermal theories which satisfy a certain “nuclearity condition” (see, e.g., [BW] [BD'AL 90a] [BD'AL 90b] [BY] for related work). Consequently, we can single out (generalized) sequences \( \Lambda_i = (O_\delta^{(i)}, \hat{O}'^{(i)}) \) such that the limit points

\[
\omega_\beta'(a) := \lim_{i \to \infty} \omega_{\Lambda_i}(a), \quad a \in A,
\]

are KMS states for the new temperature \( 1/\beta' \) (\( 0 \leq \beta' \leq \infty \)). We emphasize that phase transitions are not excluded by our method: by choosing different “boundary conditions” we may encounter disjoint KMS states for the new temperature in the thermodynamic limit.

Loosely speaking, we provide a method to heat up or cool down a quantum field theory.

2 Definitions and preliminary results

For the Lagrangian formulation of a thermal field theory we refer the reader to the books by Kapusta [Ka], Le Bellac [L] and Umezawa [U], and the excellent review article by Landsman and van Weert [LvW]. Recent work in the Wightman framework can be found in [BB 92] [BB 95] [BB 96] [St]. In this section we will outline the basic structure of a thermal field theory in the algebraic framework.

2.1 List of assumptions

Although it would be more natural—from the viewpoint of algebraic quantum statistical mechanics—to start from a \( C^* \)-dynamical system \( (A, \tau) \) and then characterize equilibrium states \( \omega_\beta \) and thermal representations \( \pi_\beta \) with respect to the dynamics, we will assume here that we are given a thermal field theory \( O \to \mathcal{R}_\beta(O) \) acting on some Hilbert space \( \mathcal{H}_\beta \). How we can reconstruct a \( C^* \)-dynamical system \( (A, \tau) \) from the \( W^* \)-dynamical system \( (\mathcal{R}_\beta, \hat{\tau}) \) is well known and will be indicated in the next subsection (\( \hat{\tau} \) will be defined in (2.1)).

We now provide a list of assumptions:

i.) (Thermal QFT). A thermal QFT is specified by a von Neumann algebra \( \mathcal{R}_\beta \), acting on a separable Hilbert space \( \mathcal{H}_\beta \), together with a net

\[
(\text{Net structure}) \quad O \to \mathcal{R}_\beta(O), \quad O \subset \mathbb{R}^4,
\]

of subalgebras associated with open bounded space-time regions \( O \) in Minkowski space. The net \( O \to \mathcal{R}_\beta(O) \) satisfies

\[
(\text{Isotony}) \quad \mathcal{R}_\beta(O_1) \subset \mathcal{R}_\beta(O_2) \quad \text{if} \quad O_1 \subset O_2
\]

and

\[
(\text{Locality}) \quad \mathcal{R}_\beta(O_1) \subset \mathcal{R}_\beta(O_2)' \quad \text{if} \quad O_1 \subset O_2'.
\]

As before, \( O' \) denotes the space-like complement of \( O \).

We have simplified the notation here. In fact, we will have to adjust the relative sizes of a triple \( \Lambda_i = (O_\delta^{(i)}, \hat{O}'^{(i)}, \hat{O}'^{(i)}) \) of space-time regions.

4
ii.) (Dynamical law). The time-evolution \( \hat{\tau}: t \mapsto \hat{\tau}_t \),

\[
\hat{\tau}_t(\cdot) = e^{i H_\beta t} \cdot e^{-i H_\beta t},
\]
is induced by a strongly continuous one-parameter group of unitaries \( \{e^{i H_\beta t}\}_{t \in \mathbb{R}} \). It acts geometrically, i.e., \( \hat{\tau}(R_\beta(O)) \subset R_\beta(O + te) \) for all \( t \in \mathbb{R} \). Here \( e \) is the unit-vector in the time-direction in the Lorentz-frame distinguished by the KMS state.

iii.) (Unique KMS vector). There exists a distinguished vector \( \Omega_\beta \), cyclic and separating for \( R_\beta \), such that the associated vector state \( \omega_\beta(\cdot) := (\Omega_\beta, \cdot) \) satisfies the KMS condition \( \mathbb{1} \) w.r.t. the time-evolution \( \tau \). Restricting attention to pure phases we assume that \( \Omega_\beta \) is the unique—up to a phase—normalized eigenvector with eigenvalue \( \{0\} \) of \( H_\beta \).

iv.) (Reeh-Schlieder property). The KMS vector \( \Omega_\beta \) is cyclic and separating for the local algebra \( R_\beta(O) \), if the space-like complement of \( O \subset \mathbb{R}^4 \) is not empty.

v.) (Nuclearity condition). The thermal field theory \( O \to R_\beta(O) \) has the following phase-space properties: for \( O \) bounded the maps \( \Theta_{\alpha,O}: R_\beta(O) \to \mathcal{H}_\beta \) given by

\[
\Theta_{\alpha,O}(A) = e^{-\alpha H_\beta} A \Omega_\beta, \quad 0 \leq \alpha \leq 1/2,
\]
are nuclear for \( 0 < \alpha < 1/2 \) and the nuclear norm (for \( \alpha \searrow 0 \) or \( \alpha \nearrow 1/2 \) and large diameters \( r \) of \( O \)) satisfies

\[
\| \Theta_{\alpha,O} \| \leq e^{c_r d (1/2 - \alpha)^{-m}},
\]
where \( c, m, d \) are positive constants. (We expect that the constant \( d \) in this bound can be put equal to the dimension of space in realistic theories, but we do not make such an assumption here. The constant \( m > 0 \) may depend on the interaction and the KMS state.)

vi.) (Regularity from the outside). The net \( O \to R_\beta(O) \) is regular from the outside, i.e.,

\[
\bigcap_{O^{(i)} \supset O} R_\beta(O^{(i)}) = R_\beta(O), \quad O^{(i)} \subset O.
\]
(This property can usually be achieved by defining the local algebras in an appropriate way.)

vii.) (Cluster assumption). Let \( O_o \) and \( O \) be two space-time regions such that \( O_o + te \subset O \) for \( |t| < \delta_o \). Let \( J \) denote the modular conjugation (see Subsection 2.3) for the pair \( (R_\beta, \Omega_\beta) \). Let \( M_j \in R_\beta(O_o) \vee JR_\beta(O_o)J \) and \( N_j \in (R_\beta(O) \vee JR_\beta(O)J)^\perp \). Then, for \( \delta_o \) large compared to the thermal wave-length \( \beta \),

\[
\sum_{j=1}^N (\Omega_\beta, M_j \Omega_\beta)(\Omega_\beta, N_j \Omega_\beta) - (\Omega_\beta, M_j N_j \Omega_\beta) \leq c' \delta_o^{-\gamma} \cdot \left( \sum_{j=1}^N M_j N_j \right),
\]
where \( c', d' \) and \( \gamma \) are positive constants which do not depend on \( O_o \) or \( O \). Here \( r_o \) denotes the diameter of \( O_o \).

Remarks.

i.) The Reeh-Schlieder property is a consequence \[\text{Ja 00}\] of additivity\(^3\) and the relativistic KMS condition proposed by Bros and Buchholz \[\text{BB 94}\]. If the KMS state is locally normal

\(^3\)The net \( O \to R_\beta(O) \) is called additive if \( \cup_i O_i = O \Rightarrow \vee_i R_\beta(O_i) = R_\beta(O) \). Here \( \vee_i R_\beta(O_i) \) denotes the von Neumann algebra generated by the algebras \( R_\beta(O_i) \).
w.r.t. the vacuum representation, then the standard KMS condition (together with additivity of the net in the vacuum representation) is sufficient to ensure the Reeh-Schlieder property of the KMS vector $\Omega_\beta$ [3].

ii.) If the KMS state is locally normal w.r.t. the vacuum representation, then it is sufficient to assume that

$$\bigcap_{\hat{O}(i) \supset O} \mathcal{R}(\hat{O}(i)) = \mathcal{R}(O), \quad \hat{O}(i) \backslash \hat{\chi}(O),$$

holds true in the vacuum representation. For the free scalar field this property was shown by Araki [A 64].

iii.) One might try to establish the cluster condition starting from a sharper nuclearity condition. For instance, we might assume that the map $\Theta^\dagger_{\alpha,O}: \mathcal{R}_\beta(O) \to \mathcal{H}_\beta$ given by

$$\Theta^\dagger_{\alpha,O}(A) = e^{-\alpha|H_\beta|} (A - (\Omega_\beta, A\Omega_\beta))\Omega_\beta, \quad \alpha > 0,$$

is nuclear too and satisfies (for $\alpha^m$ large in comparison with $r^d$) the following bound on its nuclear norm

$$\|\Theta^\dagger_{\alpha,O}\| \leq c' \cdot r^d \cdot \alpha^{-m}.$$  

Formally the bound on the nuclear norm $\|\Theta^\dagger_{\alpha,O}\|$ follows from taking the limit $\alpha^m$ large in comparison with $r^d$ in the expression $\exp(c r^d \alpha^{-m}) - 1$, where the one is due to the subtraction of the thermal expectation value. (The expression $\exp(c r^d \alpha^{-m})$ should provide an upper bound for the nuclear norm of the map $A \mapsto \exp(-\alpha|H_\beta|) A\Omega_\beta$, where $\alpha > 0$.)

iv.) The product state appearing in (3) is induced by a product vectors $\chi_i$, which satisfies

$$(\chi_i, MN\chi_i) = (\Omega_\beta, M\Omega_\beta)(\Omega_\beta, N\Omega_\beta)$$

for $M \in \mathcal{M}_\beta(O_\beta^{(i)})$ and $N \in \mathcal{M}_\beta(O^{(i)})'$. The convergence of the product vector $\chi \to \Omega_\beta$ follows from $(\sqcup_{\mathcal{O}} \mathcal{M}_\beta(O))' = 1$ (see [D'ADFIR]).

### 2.2 The restricted $C^*$-dynamical system

If the weakly continuous one-parameter group $\tau: t \mapsto \tau_t$ fails to be strongly continuous, then we can reconstruct the underlying $C^*$-dynamical system by a suitable smoothening procedure (once again we refer to [S 1.18]): given a thermal field theory $O \to \mathcal{R}_\beta(O)$ there exists

(i) a $C^*$-algebra $A$ and a representation $\pi_\beta: A \to \mathcal{B}(\mathcal{H}_\beta)$ such that $\pi_\beta(A)$ is a $\sigma$-weakly dense $C^*$-subalgebra of $\mathcal{R}_\beta$;

(ii) a net $O \to A(O)$ of $C^*$-subalgebras of $A$ such that $\pi_\beta(A(O))$ is a $\sigma$-weakly dense $C^*$-subalgebra of $\mathcal{R}_\beta(O)$ for all $O \subset \mathbb{R}^4$;

(iii) a strongly continuous automorphism group $t \mapsto \tau_t$ of $A$ such that $\pi_\beta(\tau_t(a)) = \tau_t(\pi_\beta(a))$ for all $a \in A$.

Moreover, the net $O \to A(O)$ satisfies isotony and locality and $\tau$ respects the local structure of the net $O \to A(O)$, i.e., $\tau_t(A(O)) = A(O + tc)$ for $t \in \mathbb{R}$.

We can now introduce subalgebras $A_E$ of almost local elements in $A$ which are analytic with respect to time-translations [Bju 89]. For the existence of these subalgebras it is crucial that the time-evolution $t \mapsto \tau_t$ is strongly continuous, i.e., if we fix some $a \in A$, then $\lim_{t \to 0} \|\tau_t(a) - a\| = 0.$
Lemma 2.1. (Buchholz and Junglas). Let \( p \in \mathbb{N} \) be fixed and let \( \mathcal{A}_p \subset \mathcal{A} \) be the \(*\)-algebra generated by all finite sums and products of operators of the form

\[
    a(f) = \int dt \, f(t) \tau_t(a),
\]

where \( f \) is any one of the functions

\[
    f(t) = \text{const.} \, e^{-\kappa(t+w)^{2p}}
\]

(with \( \kappa > 0, \, w \in \mathbb{C} \)) and \( a \in \cup_{\mathcal{O}} \mathcal{A}(\mathcal{O}) \) is any strictly local operator. It follows that

(i) each \( b \in \mathcal{A}_p \) is an analytic element with respect to \( \tau \), i.e., the operator-valued function \( t \mapsto \tau_t(b) \) can be extended to a holomorphic function on \( \mathbb{C} \);

(ii) each \( b \in \mathcal{A}_p \) is almost local in the sense that for any \( r^{(i)} > 0 \) there is a local operator \( b^{(i)} \in \mathcal{A}(\mathcal{O}^{(i)}) \) such that

\[
    \|b^{(i)} - b\| \leq C e^{-\kappa(r^{(i)/2})^{2p}}, \quad \kappa > 0,
\]

where the constant \( C > 0 \) does not depend on \( r^{(i)} \);

(iii) the algebra \( \mathcal{A}_p \) is invariant under \( \tau_z, \, z \in \mathbb{C} \), and norm dense in \( \mathcal{A} \).

The new state \( \omega_{\beta'} \), which we will construct in the sequel, will be a \((\tau, \beta')\)-KMS state for the pair \((\mathcal{A}, \tau)\). More precisely, it will satisfy the KMS condition (1) for \( a, b \in \mathcal{A}_p \) for some \( p \) (\( p \) will be specified in Subsection 4.3). As we have just seen, \( \mathcal{A}_p \) is a norm dense, \( \tau \)-invariant subalgebra of \( \mathcal{A}_\tau \).

Remark. If the new state \( \omega_{\beta'} \) is locally normal w.r.t. \( \pi_{\beta} \), then one might expect that the KMS condition extends to

\[
    \mathcal{F} := \bigcup_{\mathcal{O} \in \mathbb{R}^4} \mathcal{R}_{\beta}(\mathcal{O}).
\]

However, the representations \( \pi_{\beta'} \) and \( \pi_{\beta} \) of \( \mathcal{F} \) will be inequivalent for \( \beta' \neq \beta \), and therefore the weak closures \( \pi_{\beta'}(\mathcal{F})'' \) and \( \pi_{\beta}(\mathcal{F})'' \) will in general be non-isomorphic.

2.3 The opposite net of local algebras

By assumption the KMS vector \( \Omega_{\beta} \) is cyclic and separating for \( \mathcal{R}_{\beta} \). Thus Tomita-Takesaki theory applies: the polar decomposition of the closeable operator \( S_\beta : A \Omega_{\beta} \mapsto A^* \Omega_{\beta}, \, A \in \mathcal{R}_{\beta} \), provides a conjugate-linear isometric mapping \( J \) from \( \mathcal{H}_{\beta} \) onto \( \mathcal{H}_{\beta} \) and a positive self-adjoint (in general, unbounded, but densely defined and invertible) operator \( \Delta \) acting on \( \mathcal{H}_{\beta} \). The modular conjugation \( J \) satisfies \( J^2 = 1 \) and

\[
    J \Delta^{1/2} A \Omega_{\beta} = A^* \Omega_{\beta} \quad \forall A \in \mathcal{R}_{\beta}.
\]

\( \Delta \) is called the modular operator. \( J \) induces a \(*\)-anti-isomorphism \( j : A \mapsto J A^* J \) between the algebra of quasi-local observables \( \mathcal{R}_{\beta} \) and its commutant (Tomita’s theorem). The opposite net

\[
    \mathcal{O} \rightarrow j(\mathcal{R}_{\beta}(\mathcal{O})), \quad \mathcal{O} \subset \mathbb{R}^4,
\]

provides a perfect mirror image of the net of local observables. The unitary operators \( \Delta^s \), \( s \in \mathbb{R} \), induce a one-parameter group of \(*\)-automorphism \( \sigma : s \mapsto \sigma_s \) of \( \mathcal{R}_\beta \),

\[
    \sigma_s(A) = \Delta^s A \Delta^{-s}, \quad s \in \mathbb{R}, \quad A \in \mathcal{R}_\beta.
\]
σ is called the modular automorphism. Takesaki has shown that ωβ is a (σ, −1)-KMS state. Moreover, σ is uniquely determined by this condition and consequently ∆is = exp(−isβHβ).

We conclude that in a thermal field theory the modular automorphism σ coincides—up to a scaling factor—with the time-evolution ˆτ. Consequently, the modular automorphism respects the net structure too, i.e.,

\[ \sigma_s(\mathcal{R}_β(\mathcal{O})) = \mathcal{R}_β(\mathcal{O} + sβ \cdot e) \quad \forall s \in \mathbb{R}. \]

The real parameter β ∈ ℝ+ appearing (until now β was just a dummy index) in \( \mathcal{R}_β \) distinguishes a length scale, which is called the thermal wave-length. In fact, we can turn the argument up side down: given a thermal field theory \( O \rightarrow \mathcal{R}_β(\mathcal{O}) \), it is not necessary to provide an explicit expression for the effective Hamiltonian \( H_β \). It is already uniquely specified by the pair \( (\mathcal{R}_β, \Omega_β) \): by Stone’s theorem there exists a unique self-adjoint generator \( H_β \) such that \( \Delta = \exp(−βH_β) \). Modular theory implies that for \( 0 ≤ β < ∞ \) the operator \( H_β \) is not semi-bounded but its spectrum is symmetric and consists typically of the whole real line \[ A_72 \] [BW].

### 2.4 Doubling the degrees of freedom

We now present the first step of our construction, which can be understood as a local purification. Consider some \( δ > 0 \) and two space-time regions \( O \) and \( \hat{O} \) such that \( O + te ⊂ \hat{O} \) for \( |t| < δ \). In a forthcoming paper [Ja 04] we will show that the so-called split property for the net of von Neumann algebras \( O \rightarrow \mathcal{R}_β(\mathcal{O}) \) follows from the nuclearity condition [2]. It asserts that there exists a type I factor \( N \) such that

\[ \mathcal{R}_β(O) ⊂ N ⊂ \mathcal{R}_β(\hat{O}). \]

**Remark.** If the KMS state is locally normal w.r.t. the vacuum representation, then the split property for the vacuum representation automatically implies the split property for the thermal representation.

The following result is a consequence of the split inclusion [5].

**Lemma 2.2.** Let \( O \) be an open and bounded space-time region. Then the von Neumann algebra

\[ \mathcal{M}_β(O) := \mathcal{R}_β(O) \vee j(\mathcal{R}_β(O)) \]

is naturally isomorphic to the tensor product of \( \mathcal{R}_β(O) \) and \( j(\mathcal{R}_β(O)) \). I.e., there exists a unitary operator \( V: \mathcal{H}_β \rightarrow \mathcal{H}_β \otimes \mathcal{H}_β \) such that

\[ V\mathcal{M}_β(O)V^* = \mathcal{R}_β(O) \otimes j(\mathcal{R}_β(O)). \]

**Proof.** The split property [5] implies that there exists a product vector \( Ω_p ∈ \mathcal{H}_β \), cyclic and separating for \( \mathcal{R}_β(O) \vee \mathcal{R}_β(\hat{O})' \), such that

\[ (Ω_p, ABΩ_p) = (Ω_β, AΩ_β)(Ω_β, BΩ_β) \]

for all \( A \in \mathcal{R}_β(O) \) and \( B ∈ \mathcal{R}_β(\hat{O})' \) [La 04]. The product vector \( Ω_p \) can be utilized to define a linear operator \( V: \mathcal{H}_β \rightarrow \mathcal{H}_β \otimes \mathcal{H}_β \) by linear extension of

\[ VABΩ_p = AΩ_β \otimes BΩ_β, \]
where $A \in \mathcal{R}_\beta(O)$ and $B \in \mathcal{R}_\beta(\hat{O})'$. The operator $V$ is unitary. Inspecting (7) we find

\[(8) \quad VR_\beta(O)V^* = R_\beta(O) \otimes I \quad \text{and} \quad VR_\beta(\hat{O})'V^* = I \otimes \mathcal{R}_\beta(\hat{O})'.\]

The inclusion $j(R_\beta(O)) \subset \mathcal{R}_\beta(\hat{O})'$ implies that the von Neumann algebra $\mathcal{M}_\beta(O)$ is naturally isomorphic to the tensor product of $\mathcal{R}_\beta(O)$ and $j(R_\beta(O))$ and the relation (8) is a consequence of (7).

\[\Box\]

**Remark.** The algebras $\mathcal{R}_\beta(O)$ and $j(R_\beta(O))$ are weakly statistically independent, i.e., $0 \neq A \in \mathcal{R}_\beta(O)$ and $0 \neq B \in j(R_\beta(O))$ implies $AB \neq 0$ (Schlieder property). In this sense one can speak of a doubling of degrees of freedom.

The elements of $\mathcal{M}_\beta(O)$ will in general not show analyticity properties with respect to $\Omega_\beta$. Thus it seems that the essence of a thermal field theory gets lost, when we ‘double the degrees of freedom’ and consider the net $O \to \mathcal{M}_\beta(O)$ instead of the net of observables $O \to \mathcal{R}_\beta(O)$.

But, due to the natural tensor product structure of $\mathcal{M}_\beta(O)$, we can recover certain analyticity properties w.r.t. $\Omega_\beta$ and a new auxiliary one-parameter group of unitary operators:

**Definition.** A one-parameter group of unitary operators $s \mapsto \Delta_p^{-s} : \mathcal{H}_\beta \to \mathcal{H}_\beta$, $s \in \mathbb{R}$, and an anti-unitary operator $J_p : \mathcal{H}_\beta \to \mathcal{H}_\beta$ are given by linear extension of

\[(9) \quad \Delta_p^{-s}AB\Omega_p := V^*(\Delta^{-is}A\Omega_\beta \otimes \Delta^{is}B\Omega_\beta), \quad s \in \mathbb{R},\]

and, respectively,

\[J_pAB\Omega_p := V^*(J\Delta^{-is}A\Omega_\beta \otimes J\Delta^{is}B\Omega_\beta),\]

where $A \in \mathcal{R}_\beta(O)$ and $B \in \mathcal{R}_\beta(\hat{O})'$.

By Stone’s theorem there exists a unique self-adjoint operator $H_p$ such that

\[\Delta_p = e^{-\beta H_p} \quad \text{and} \quad H_p\Omega_p = 0.\]

The vector $\Omega_p \in \mathcal{H}_\beta$ is cyclic and separating for $\mathcal{R}_\beta(O) \vee \mathcal{R}_\beta(\hat{O})'$. It follows from the definition (7) of $V$ and the Reeh-Schlieder property of $\Omega_\beta$ that the product vector $\Omega_p$ is cyclic (and of course separating) for $\mathcal{M}_\beta(O)$ too.

**Theorem 2.3.** Let $O_o$ and $O$ be two space-time regions such that $O_o \cup t \subset O$ for $|t| < \delta_o$. Then

(i) $\Delta_p^{-is}$ respects the local structure of $\mathcal{M}_\beta(O)$ for $|s|$ sufficiently small, i.e.,

\[(10) \quad \Delta_p^{-is}\mathcal{M}_\beta(O_o)\Delta_p^{is} \subset \mathcal{M}_\beta(O_o + s\beta \cdot e) \quad \forall |s\beta| < \delta_o.\]

(ii) The group of unitaries $s \mapsto \Delta_p^{-is}$ coincides for $a \in \mathcal{A}(O_o)$ and $|s\beta| < \delta_o$—up to rescaling— with the time-evolution, i.e.,

\[\Delta_p^{-is}\pi_\beta(a)\Delta_p^{is} = \pi_\beta(\tau_s(a))\]

for $|s\beta| < \delta_o$. 

9
Proof. The inclusion follows from the definition of \( \Delta_p \) and the inclusions
\[
\hat{\tau}_t(R_{\beta}(O_\omega)) \subset R_{\beta}(O_\omega + te) \quad \text{and} \quad \hat{\tau}_t(j(R_{\beta}(O_\omega))) \subset j(R_{\beta}(O_\omega + te)),
\]
which hold for \(|t| < \delta_0\). \( \square \)

**Lemma 2.4.** Consider some \( M \) in \((9)\). Then \( 0, \) the spectral resolution of the positive operator \( \Delta_p \),

Proof. By definition, \( J_p^2 = \mathbb{1}, \) \( J_p \Omega_p = \Omega_p \) and

\[
J_p \Delta_p^{1/2} AB \Omega_p = V^* (A^* \Omega_\beta \otimes B^* \Omega_\beta) = A^* B^* \Omega_p = (AB)^* \Omega_p
\]

for all \( A \in R_{\beta}(O) \) and \( B \in j(R_{\beta}(O)) \). Since \( p^\alpha \leq \max(1, p) < 1 + p \) for \( 0 \leq \alpha \leq 1 \) and \( p > 0 \), the spectral resolution of the positive operator \( \Delta_p^{1/2} \) implies that \( M_{\beta}(O) \Omega_p \subset \mathcal{D}(\Delta_p^\alpha) \) for \( 0 \leq \alpha \leq 1/2 \). \( \square \)

Nevertheless, \( J_p \) and \( \Delta_p \) are not the modular objects associated to \((M_{\beta}(O), \Omega_p)\).

**Theorem 2.5.** Let \( O_\omega \) and \( O \) be two space-time regions such that \( O + te \subset O \) for \(|t| < \delta_0\). Then the inclusion of von Neumann algebras \( M_{\beta}(O_\omega) \subset M_{\beta}(O) \) is a standard split inclusion and there exists a unitary operator \( W: \mathcal{H}_\beta \to \mathcal{H}_\beta \otimes \mathcal{H}_\beta \) such that

\[
WM_{\beta}(O_\omega)W^* = M_{\beta}(O_\omega) \otimes \mathbb{1} \quad \text{and} \quad WM_{\beta}(O)W^* = \mathbb{1} \otimes M_{\beta}(O)'.
\]

(A split inclusion \( A \subset B \) is called standard (see [DL]), if there exists a vector \( \Omega \) which is cyclic for \( A' \cap B \) as well as for \( A \) and \( B \).)

Proof. From the split inclusions

\[
R_{\beta}(O_\omega) \subset N_\omega \subset R_{\beta}(O) \quad \text{and} \quad j(R_{\beta}(O_\omega)) \subset j(N_\omega) \subset j(R_{\beta}(O))
\]

we infer that there exists a type I factor, namely \( N_\omega \vee j(N_\omega) \), such that

\[
M_{\beta}(O_\omega) \subset N_\omega \vee j(N_\omega) \subset M_{\beta}(O).
\]

All infinite type I factors with infinite commutant on the separable Hilbert space \( \mathcal{H}_\beta \) are unitarily equivalent to \( \mathcal{B}(\mathcal{H}_\beta) \otimes \mathbb{1} \) ([KR], Chapter 9.3). Thus there exists a unitary operator \( W: \mathcal{H}_\beta \to \mathcal{H}_\beta \otimes \mathcal{H}_\beta \) such that \( N_\omega \vee j(N_\omega) = W^* (\mathcal{B}(\mathcal{H}_\beta) \otimes \mathbb{1}) W \). Now consider \( \omega_{\beta}(\cdot) := (\Omega_{\beta}, \beta\Omega_{\beta}) \) and \( \omega_{\beta}(\cdot) := (\Omega_{\beta}, \Omega_{\beta}) \) as two normal states over \( M_{\beta}(O_\omega) \) and \( M_{\beta}(O)' \), respectively. Set

\[
\phi_p(C) := (\omega_{\beta} \otimes \omega_{\beta})(WCW^*) \quad \forall C \in M_{\beta}(O_\omega) \vee M_{\beta}(O)'.
\]

Then \( \phi_p \) is a normal state over \( M_{\beta}(O_\omega) \vee M_{\beta}(O)' \), which satisfies \( \phi_p(MN) = \omega_{\beta}(M) \cdot \omega_{\beta}(N) \) for all \( M \in M_{\beta}(O_\omega) \) and \( N \in M_{\beta}(O)' \). In the presence of a separating vector each normal state is a vector state ([KR 7.2.3]). In fact, there exists a unique vector \( \eta \) in the natural positive cone \( P^+(M_{\beta}(O_\omega) \vee M_{\beta}(O)' \vee \Omega_{\beta}) \) such that

\[
(\eta, M_{\beta}(O_\omega) \vee M_{\beta}(O)' \vee \Omega_{\beta}) = \phi_p(MN) = (\Omega_{\beta}, M_{\beta}(O_\omega) \vee M_{\beta}(O)' \vee \Omega_{\beta})
\]

for all \( M \in M_{\beta}(O_\omega) \) and \( N \in M_{\beta}(O)' \) ([BR 2.5.31]). Thus the operator \( W: \mathcal{H}_\beta \to \mathcal{H}_\beta \otimes \mathcal{H}_\beta \) can now be specified by linear extension of

\[
WMN\eta = M_{\beta}(O_\omega) \vee N_{\beta}(O_\omega),
\]

\( 10 \)
where \( M \in \mathcal{M}_\beta(O_o) \) and \( N \in \mathcal{M}_\beta(O)' \). Consequently,

\[
WM_\beta(O_o)W^* = M_\beta(O_o) \otimes \mathbb{1} \quad \text{and} \quad WM_\beta(O)'W^* = \mathbb{1} \otimes M_\beta(O)'.
\]

The vector \( \Omega_\beta \) is cyclic and separating for \( \mathcal{M}_\beta(O_o) \) and the vector \( \Omega_p \) is cyclic and separating for \( \mathcal{M}_\beta(O)' \). Thus the vector \( \Omega_\beta \otimes \Omega_p \) is cyclic and separating for \( \mathcal{M}_\beta(O_o) \otimes \mathcal{M}_\beta(O)' \) and the split inclusion \( \mathcal{M}_\beta(O_o) \subset \mathcal{M}_\beta(O) \) is standard.

\[\square\]

## 3 Localized excitations of a KMS state

Taking the auxiliary structure developed in the previous section into account, we can now adapt the method of Buchholz and Junglas to thermal representations.

### 3.1 Consequences of the nuclearity condition

Imposing strict localization on an excitation (see Proposition 3.3 (iii) below) does not lead to a convenient notion. The split property provides the key to a more convenient definition of a localized excitation. However, it leaves a lot of freedom, for instance one could request additional properties for some subregion in \( O_o \cap \hat{O} \). In this sense the following definition only provides one possible choice, fixed by choosing a specific product vector \( \eta \).

**Definition.** Let \( O_o, O \) and \( \hat{O} \) denote three space-time regions such that for some \( \delta_o, \delta > 0 \)

\[
(12) \quad O_o + te \subset O \quad \forall |t| < \delta_o \quad \text{and} \quad O + te \subset \hat{O} \quad \forall |t| < \delta.
\]

The Hilbert space \( \mathcal{H}_\Lambda \subset \mathcal{H}_\beta, \Lambda := (O_o, O, \hat{O}) \), of localized excitations of the KMS state \( \omega_\beta \) is given by

\[
(13) \quad \mathcal{H}_\Lambda := \overline{M_\beta(O_o)\eta}.
\]

The projection onto \( \mathcal{H}_\Lambda \) is denoted by \( E_\Lambda \).

**Notation.** Here \( \mathcal{M}_\beta(O_o) \) denotes the von Neumann algebra generated by \( \mathcal{R}_\beta(O_o) \) and \( j(\mathcal{R}_\beta(O_o)) \) and \( \eta \in \mathcal{H}_\beta \) denotes the unique\(^4\) product vector in the natural positive cone \( \mathcal{P}^2(\mathcal{M}_\beta(O_o) \vee \mathcal{M}_\beta(O)', \Omega_\beta) \) satisfying

\[
(14) \quad (\eta, MN\eta) = (\Omega_\beta, M\Omega_\beta)(\Omega_p, N\Omega_p)
\]

for all \( M \in \mathcal{M}_\beta(O_o) \) and \( N \in \mathcal{M}_\beta(O)' \). As before, \( \Omega_p \) denotes the unique product vector in the natural positive cone \( \mathcal{P}^2(\mathcal{R}_\beta(O) \vee \mathcal{R}_\beta(\hat{O})', \Omega_\beta) \) satisfying

\[
(15) \quad (\Omega_p, AB\Omega_p) = (\Omega_\beta, A\Omega_\beta)(\Omega_\beta, B\Omega_\beta)
\]

for all \( A \in \mathcal{R}_\beta(O) \) and \( B \in \mathcal{R}_\beta(\hat{O})' \).

\(^4\)Fixing the product vector with respect to some natural positive cone is mathematically convenient, but not necessary. In fact, we expect that different ‘boundary conditions’ are realized by different choices of \( \eta \). In the thermodynamic limit different choices of the boundary conditions might lead to different phases.
Note that $W$—as specified in (11)—is unitary and $WMNW^* = M \otimes N$ for $M \in \mathcal{M}_\beta(\mathcal{O}_o)$ and $N \in \mathcal{M}_\beta(\mathcal{O})'$. Using the isometry $W$ we can write
\[
\mathcal{H}_\Lambda = W^*\mathcal{M}_\beta(\mathcal{O}_o)\Omega_\beta \otimes \Omega_p = W^*(\mathcal{H}_\beta \otimes \Omega_p)
\]
and $E_\Lambda = W^*(1 \otimes P_{\Omega_p})W$. Here $P_{\Omega_p} \in \mathcal{B}(\mathcal{H}_\beta)$ denotes the projection onto $\mathcal{C} \cdot \Omega_p$.

The following proposition summarizes the properties of the Hilbert space $\mathcal{H}_\Lambda$. It justifies the claim stated at the beginning of this subsection.

**Proposition 3.1.** Given a triple $\Lambda := (\mathcal{O}_o, \mathcal{O}, \hat{\mathcal{O}})$ of space-time regions as specified in (12) we find:

(i) The Hilbert space $\mathcal{H}_\Lambda$ is invariant under the action of elements of $\mathcal{M}_\beta(\mathcal{O}_o)$, i.e.,
\[
\mathcal{M}_\beta(\mathcal{O}_o)\mathcal{H}_\Lambda = \mathcal{H}_\Lambda.
\]
(ii) Vectors in $\mathcal{H}_\Lambda$ induce product states for the pair $(\mathcal{M}_\beta(\mathcal{O}_o), \mathcal{M}_\beta(\mathcal{O})')$: if $\Psi \in \mathcal{H}_\Lambda$, then
\[
(\Psi, MN\Psi) = (\Psi, M\Psi)(\Omega_p, N\Omega_p)
\]
for all $M \in \mathcal{M}_\beta(\mathcal{O}_o)$ and $N \in \mathcal{M}_\beta(\mathcal{O})'$.
(iii) The vector states associated with $\mathcal{H}_\Lambda$ represent strictly localized excitations of the KMS state, i.e., they coincide with the original KMS state $\omega_\beta$ in the space-like complement of $\hat{\mathcal{O}}$: if $\Psi \in \mathcal{H}_\Lambda$, then
\[
(\Psi, \pi_\beta(a)\Psi) = \omega_\beta(a) \quad \forall a \in \mathcal{A}^c(\hat{\mathcal{O}}).
\]
Here $\mathcal{A}^c(\hat{\mathcal{O}})$ denotes the $C^*$-algebra generated by \{ $a \in \mathcal{A} : [a, b] = 0 \forall b \in \mathcal{A}(\hat{\mathcal{O}})$ \} and not the commutant of $\pi_\beta(\mathcal{A}(\hat{\mathcal{O}}))$ in $\mathcal{B}(\mathcal{H}_\beta)$.
(iv) $\mathcal{H}_\Lambda$ is complete in the following sense: to every normal state $\phi$ on $\mathcal{M}_\beta(\mathcal{O}_o)$ there exists a $\Phi \in \mathcal{H}_\Lambda$ such that $(\Phi, M\Phi) = \phi(M)$ for all $M \in \mathcal{M}_\beta(\mathcal{O}_o)$.

**Proof.** We simply adapt the proof of the corresponding result by Buchholz and Junglas to our situation:

(i) follows from the definition;
(ii) follows from (13) and (14);
(iii) follows from (13), (14) and (15);
(iv) Since $\mathcal{M}_\beta(\mathcal{O}_o)$ has a cyclic and separating vector, there exists a vector $\Phi \in \mathcal{H}_\beta$ which induces the given normal state $\phi$ on $\mathcal{M}_\beta(\mathcal{O}_o)$. It follows that the vector $\Phi := W^*(\Phi \otimes \Omega_p) \in \mathcal{H}_\Lambda$ satisfies (iv). 

We need one more lemma, in order to show that the restriction of the operator $\Delta^\alpha_p$ to the subspace $\mathcal{H}_\Lambda$ is trace class for $0 < \alpha < 1/2$.

**Lemma 3.2.** Assume that the nuclearity condition (2) holds true. It follows that

(i) the maps $\vartheta_{\alpha, \mathcal{O}} : \mathcal{M}_\beta(\mathcal{O}) \to \mathcal{H}_\beta$, $M \mapsto \Delta^\alpha_p M\Omega_p$, $0 \leq \alpha \leq 1/2$,

are nuclear for $0 < \alpha < 1/2$.
(ii) the nuclear norm of $\vartheta_{\alpha,\mathcal{O}}$ is bounded by
\[
\|\vartheta_{\alpha,\mathcal{O}}\| \leq e^{2r^d(\alpha^{-m}+(1/2-\alpha)^{-m})}, \quad c, m, d > 0,
\]
where $r$ denotes the diameter of $\mathcal{O}$ and $c, m, d$ are the constants appearing in the bound \(\mathbb{E}\) on the nuclear norm of the map $\Theta_{\alpha,\mathcal{O}}$.

**Proof.** Let $A \in \mathcal{R}_\beta(\mathcal{O})$ and $B \in j(\mathcal{R}_\beta(\mathcal{O}))$. By definition,
\[
\vartheta_{\alpha,\mathcal{O}}(AB) = V^* (\Delta^\alpha A\Omega_\beta \otimes \Delta^{-\alpha} B\Omega_\beta).
\]
The maps $A \mapsto \Delta^\alpha A\Omega_\beta$ and $B \mapsto \Delta^{-\alpha} B\Omega_\beta$ are nuclear for $0 < \alpha < 1/2$. The tensor product of two nuclear maps itself is a nuclear map and the norm is bounded by the product of the nuclear norms $\|\mathbb{E}\|
\]
Assume the nuclearity condition \(\mathbb{E}\) holds true. It follows that the operator $\Delta^\alpha_p E_\Lambda$, acting on the Hilbert space $\mathcal{H}_\beta$, is of trace-class for $0 < \alpha < 1/2$, and
\[
\text{Tr} |\Delta^\alpha_p E_\Lambda| \leq e^{2r^d(\alpha^{-m}+(1/2-\alpha)^{-m})}, \quad c, m, d > 0,
\]
where $r$ denotes the diameter of $\mathcal{O}$ and $c, m, d$ are the constants appearing in the bound \(\mathbb{E}\) on the nuclear norm of the map $\Theta_{\alpha,\mathcal{O}}$.

**Proposition 3.3.** Let $\Lambda(\mathcal{O}_o, \mathcal{O}, \mathcal{O})$ be a triple of space-time regions as specified in \(\mathbb{E}\). Assume the nuclearity condition \(\mathbb{E}\) holds true. It follows that the operator $\Delta^\alpha_p E_\Lambda$, acting on the Hilbert space $\mathcal{H}_\beta$, is of trace-class for $0 < \alpha < 1/2$, and
\[
\text{Tr} |\Delta^\alpha_p E_\Lambda| \leq e^{2r^d(\alpha^{-m}+(1/2-\alpha)^{-m})}, \quad c, m, d > 0,
\]
where $r$ denotes the diameter of $\mathcal{O}$ and $c, m, d$ are the constants appearing in the bound \(\mathbb{E}\) on the nuclear norm of the map $\Theta_{\alpha,\mathcal{O}}$.

**Proof.** The proof of this proposition is more or less identical to the one given by Buchholz and Junglas \(\mathbb{B}\) for the vacuum case. We present it for completeness only.

i.) The first step is to construct a convenient orthonormal basis of $\mathcal{H}_\Lambda$. Let $\{\Psi_i\}_{i \in \mathbb{N}}$ be an orthonormal basis of $\mathcal{H}_\beta$ with $\Psi_1 = \Omega_\beta$. Set
\[
(16) \quad U_{i,j} := W^*(M_{i,j} \otimes \mathbb{1}) W,
\]
where $M_{i,j} \in \mathcal{B}(\mathcal{H}_\beta)$ are matrix units given by
\[
M_{i,j} \Psi := (\Psi_j, \Psi) \Psi_i \quad \forall \Psi \in \mathcal{H}_\beta.
\]
Since $W^*(B(\mathcal{H}_\beta) \otimes \mathbb{1}) W = \mathcal{N}_o \vee j(\mathcal{N}_o)$, we infer from \(16\) that $U_{i,j} \in \mathcal{N}_o \vee j(\mathcal{N}_o)$. Furthermore,
\[
U^*_{i,j} = U_{j,i}, \quad U_{i,j}U_{k,l} = \delta_{j,k}U_{i,l}, \quad \text{and} \quad s - \lim_{N \to \infty} \sum_{i=1}^N U_{i,i} = \mathbb{1}.
\]
Combining \(11\) and \(16\) we find $U_{i,1} \mathbb{E} = W^*(\Psi_i \otimes \Omega_\beta)$. Thus $\{U_{i,1} \mathbb{E}\}_{i \in \mathbb{N}}$ is the desired orthonormal basis of $\mathcal{H}_\Lambda$. Note that \(11\) holds true for all $N \in (\mathcal{N}_o \vee j(\mathcal{N}_o))^\dagger$. Therefore $\|N\mathbb{E}\| = \|N\Omega_\beta\|$. Consequently, we can introduce an isometry $I \in \mathcal{N}_o \vee j(\mathcal{N}_o)$ by setting
\[
N\mathbb{E} = IN\Omega_\beta \quad \forall N \in (\mathcal{N}_o \vee j(\mathcal{N}_o))^\dagger.
\]
We can now represent the orthonormal basis $\{U_{i,1} \mathbb{E}\}_{i \in \mathbb{N}}$ by vectors $\Gamma_i := U_{i,1} \mathbb{E} = U_{i,1} \mathbb{I} \Omega_\beta$, where $U_{i,1} I \in \mathcal{N}_o \vee j(\mathcal{N}_o) \subset M_{\beta}(\mathcal{O})$. It follows that $\Gamma_i \in \mathcal{D}(\Delta^\alpha_p)$ for $0 < \alpha < 1/2$ and $i \in \mathbb{N}$. Especially, $\eta := \Gamma_1 \in \mathcal{D}(\Delta^\alpha_p)$ for $0 < \alpha < 1/2$.

ii.) Polar decomposition of the closeable operator $\Delta^\alpha_p E_\Lambda$ yields $\Delta^\alpha_p E_\Lambda = F \cdot |\Delta^\alpha_p E_\Lambda|$, where $F$ is a partial isometry with range in $\mathcal{H}_\Lambda$. Introducing a set of linear functionals $\phi_i$ (which can
for $\Psi \in \mathcal{H}_\beta$ no cuts appear in

To heat up the system locally is quite simple: For $r \in \mathcal{H}_\beta$, we find

Buchholz and Junglas have shown the following inequality $[BJ9]$

for some $\alpha$ contained in the interior of $O$ the new temperature $1/\beta$ is continuous at the boundary for $a, b$ is bounded and analytic in its domain of definition; $a, b$ is continuous at the boundary for $a, b$ is defined on $a, b$ for each subregion $O_{\delta_0} \subset O$ whose closure is contained in the interior of $O$, there exists some $\delta_0 > 0$ and a function $F_{a,b}$ for every pair of operators $a, b \in \mathcal{A}(O_{\delta_0})$ such that

Definition. Let $\beta' > 0$ and let $n \in \mathbb{N}$ be the smallest natural number such that $n \alpha \beta = \beta'$ for some $\alpha$ ($0 \leq \alpha \leq 1/2$). A state $\omega_\Lambda$ satisfies the local KMS condition at temperature $1/\beta'$ in some bounded space-time region $O_{\delta_0} \subset \mathbb{R}^4$ if for any subregion $O_{\delta_0} \subset O$ whose closure is contained in the interior of $O$, there exists some $\delta_0 > 0$ and a function $F_{a,b}$ for every pair of operators $a, b \in \mathcal{A}(O_{\delta_0})$ such that

- $F_{a,b}$ is defined on
  $$\mathcal{G}_{n,\alpha} := \{ z \in \mathbb{C} \mid 0 < z < n \alpha \beta\} \setminus \{ z \in \mathbb{C} \mid |\Re z| \geq \delta_0, \Re z = k \alpha \beta, k = 1, \ldots, n-1\};$$
- $F_{a,b}$ is bounded and analytic in its domain of definition;
- $F_{a,b}$ is continuous for $\Re z \geq k \alpha \beta$ and $\Re z \not\geq k \alpha \beta, k = 1, \ldots, n-1$;
- $F_{a,b}$ is continuous at the boundary for $\Re z \geq 0$ and $\Re z \not\geq n \alpha \beta$;
- The respective boundary values are
  $$F_{a,b}(t) = \omega_\Lambda(a \tau(t) b)$$ and $F_{a,b}(t + i \alpha \beta) = \omega_\Lambda(\tau(t) a)$ for $t < \delta_0$.

Remark. To heat up the system locally is quite simple: For $\beta' < \beta/2$ we find $n = 1$, i.e., no cuts appear in $\mathcal{G}_{1,\alpha} = \{ z \in \mathbb{C} \mid 0 < z < \alpha \beta\}$. To cool down the system locally is
more delicate. One needs at least \( n \) cuts, where \( n \) is the minimal natural number such that \( \beta' = n\alpha \beta \) \((0 < \alpha < 1/2)\). Whether or not it is useful to operate with more cuts then necessary is unknown to us.

**Proposition 3.4.** Let \( \Lambda := (\mathcal{O}_o, \mathcal{O}, \hat{\mathcal{O}}) \) be a triple of space-time regions, as specified in (12). Let \( n \in \mathbb{N} \) be the minimal natural number such that \( \beta' = n\alpha \beta \), \( 0 < \alpha < 1/2 \). Set, for \( n \) and \( \alpha \) fixed,

\[
\rho_\Lambda := \left( \frac{E_\Lambda \Delta_\rho^n E_\Lambda}{\text{Tr} \left( \Delta_\rho^n E_\Lambda \right)} \right)^n \quad \text{and} \quad \omega_\Lambda(a) := \text{Tr} \rho_\Lambda \pi_\beta(a) \quad \forall a \in \mathcal{A}.
\]

Then \( \rho_\Lambda \) is a density matrix, i.e., \( \rho_\Lambda > 0 \) and \( \text{Tr} \rho_\Lambda = 1 \), and the following statements hold true:

(i) The states \( \omega_\Lambda \) are product states, which coincide with the given KMS state \( \omega_\beta \) in the space-like complement of \( \hat{\mathcal{O}} \); i.e.,

\[
\omega_\Lambda(ab') = \omega_\Lambda(a) \omega_\beta(b')
\]

for all \( a \in \mathcal{A}(\mathcal{O}_o) \) and \( b' \in \mathcal{A}^e(\hat{\mathcal{O}}) \). As before, \( \mathcal{A}^e(\hat{\mathcal{O}}) \) denotes the \( \mathcal{C}^* \)-algebra generated by \( \{a \in \mathcal{A} \mid [a, b] = 0 \forall b \in \mathcal{A}(\hat{\mathcal{O}})\} \).

(ii) The states \( \omega_\Lambda \) are local \((\tau, n\alpha \beta)-\text{KMS states for the space-time region } \mathcal{O}_o\).

**Remark.** For \( \mathcal{O}_o, \mathcal{O}, \hat{\mathcal{O}} \to \mathbb{R}^4 \) the denominator in (17) might go to \( \infty \) or \( 0 \). In any case we will leave the representation: we will have no operator convergence, neither in the weak nor in the strong sense and therefore we can only rely on expectation values. After performing the thermodynamic limit, we will use these expectation values to construct a new representation and check whether the new state satisfies the KMS condition \( [\Xi] \). We will see that it will do so, under the assumptions we have imposed on the phase-space properties of our thermal field theory.

**Proof.** (i) Let \( a \in \mathcal{A}(\mathcal{O}_\alpha) \) and \( b' \in \mathcal{A}^e(\hat{\mathcal{O}}) \) and let \( P_{\mathcal{B}_a} \) denote the projection onto \( \mathcal{C} \cdot \Omega_p \). Since \( E_\Lambda \in \mathcal{M}_\beta(\mathcal{O}_\alpha)' \subset \pi_\beta(\mathcal{A}(\mathcal{O}_\alpha))' \), it follows that \( [E_\Lambda, \pi_\beta(a)] = 0 \). Moreover, \( E_\Lambda = W^*(\mathbb{1} \otimes P_{\mathcal{B}_a})W \) implies

\[
E_\Lambda \pi_\beta(b') E_\Lambda = \omega_\beta(b') E_\Lambda \quad \forall b' \in \mathcal{A}^e(\hat{\mathcal{O}}).
\]

Using the cyclicity of the trace we find

\[
\omega_\Lambda(ab') = \frac{\text{Tr}(E_\Lambda \Delta_\rho^n E_\Lambda)^n \pi_\beta(a) E_\Lambda \pi_\beta(b') E_\Lambda}{\text{Tr}(\Delta_\rho^n E_\Lambda)^n} = \omega_\Lambda(a) \omega_\beta(b').
\]

(ii) Consider the case \( n = 2 \). Let \( \delta_{o_o} > 0 \) and \( \mathcal{O}_{o_o} \) be an open space-time region such that \( \mathcal{O}_{o_o} + t e \subset \mathcal{O}_o \) for \( |t| < \delta_{o_o} \). Let \( a, b \in \mathcal{A}(\mathcal{O}_{o_o}) \). By assumption, \( a \tau_t(b) \in \mathcal{A}(\mathcal{O}_o) \) for \( |t| < \delta_{o_o} \). Set

\[
F_{a,b}^{(1)}(z) := \frac{\text{Tr} \pi_\beta(a) E_\Lambda \Delta_p^{-iz/\beta} \pi_\beta(b) \Delta_p^{iz/\beta} E_\Lambda \Delta_\rho^n E_\Lambda}{\text{Tr}(\Delta_\rho^n E_\Lambda)^2}
\]

for \( 0 < \Im z < \alpha \beta \). The function \( F_{a,b}^{(1)}(z) \) is analytic in its domain and continuous at the boundary. We recall that \( \Delta_p^{-it/\beta} \pi_\beta(b) \Delta_p^{it/\beta} = \pi_\beta(\tau_t(b)) \in \pi_\beta(\mathcal{A}(\mathcal{O}_o)) \) for \( |t| < \delta_{o_o} \). Using
once again the cyclicity of the trace and \( E_\Lambda \in \pi_\beta(\mathcal{A}(\mathcal{O}_\tau))' \), we conclude that

\[
\lim_{|\Re z| < \delta_0} F^{(1)}_{a,b}(z) = \frac{\text{Tr} \pi_\beta (a) E_\Lambda \pi_\beta (\tau_{R_\Lambda}(b)) \Delta_p^\alpha E_\Lambda \Delta_p^\beta E_\Lambda}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2} = \frac{\text{Tr} \pi_\beta (a \tau_{R_\Lambda}(b)) (E_\Lambda \Delta_p^\alpha E_\Lambda)^2}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2} \quad \forall |\Re z| < \delta_0.
\]

Thus

\[
(18) \quad \lim_{|\Re z| < \delta_0} F^{(1)}_{a,b}(z) = \omega_\Lambda (a \tau_{R_\Lambda}(b)) \quad \forall |\Re z| < \delta_0.
\]

On the other hand, for \(|\Re z| < \delta_0\),

\[
\lim_{\Im z \neq \alpha \beta} F^{(1)}_{a,b}(z) = \frac{\text{Tr} \pi_\beta (a) E_\Lambda \Delta_p^\alpha E_\Lambda \Delta_p^\alpha \pi_\beta (\tau_{R_\Lambda}(b)) \Delta_p^\beta E_\Lambda}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2} = \frac{\text{Tr} \pi_\beta (a) E_\Lambda \Delta_p^\alpha E_\Lambda \pi_\beta (\tau_{R_\Lambda}(b)) \Delta_p^\beta E_\Lambda}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2}.
\]

For \( \alpha \beta < \Im z < 2\alpha \beta \) we set

\[
F^{(2)}_{a,b}(z) := \frac{\text{Tr} \pi_\beta (a) E_\Lambda \Delta_p^\alpha E_\Lambda \Delta_p^{-\alpha -iz/\beta} \pi_\beta (b) \Delta_p^{2\alpha +iz/\beta} E_\Lambda}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2}.
\]

The function \( F^{(2)}_{a,b}(z) \) is analytic in its domain and continuous at the boundary. By definition,

\[
\lim_{\Im z \neq \alpha \beta} F^{(2)}_{a,b}(z) = \frac{\text{Tr} \pi_\beta (a) E_\Lambda \Delta_p^\alpha E_\Lambda \pi_\beta (\tau_{R_\Lambda}(b)) \Delta_p^\beta E_\Lambda}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2} = \lim_{\Im z \neq \alpha \beta} F^{(1)}_{a,b}(z) \quad \forall |\Re z| < \delta_0.
\]

Furthermore, \( F^{(2)}_{a,b} \) satisfies

\[
\lim_{\Im z \neq 2\alpha \beta} F^{(2)}_{a,b}(z) = \frac{\text{Tr} \pi_\beta (a) E_\Lambda \Delta_p^\alpha E_\Lambda \Delta_p^\alpha \pi_\beta (\tau_{R_\Lambda}(b)) \Delta_p^\beta E_\Lambda}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2} = \frac{\text{Tr} \pi_\beta (a) (E_\Lambda \Delta_p^\alpha E_\Lambda)^2 \pi_\beta (\tau_{R_\Lambda}(b))}{\text{Tr} (\Delta_p^\alpha E_\Lambda)^2} \quad \forall |\Re z| < \delta_0.
\]

Thus

\[
(19) \quad \lim_{\Im z \neq 2\alpha \beta} F^{(2)}_{a,b}(z) = \omega_\Lambda (\tau_{R_\Lambda}(b)a) \quad \forall |\Re z| < \delta_0.
\]

Using the Edge-of-the-Wedge theorem \[SW\] we conclude that \( F^{(1)}_{a,b} \) and \( F^{(2)}_{a,b} \) are the restrictions to the upper (resp. lower) half of the double cut strip

\[
\mathcal{G}_{2,\alpha} = \{ z \in \mathbb{C} \mid 0 < \Im z < 2\alpha \beta \} \setminus \{ z \in \mathbb{C} \mid |\Re z| \geq \delta_0, \Im z = \alpha \beta \}
\]

of a function

\[
F_{a,b}(z) := \begin{cases} F^{(2)}_{a,b}(z) & \text{for } \alpha \beta < \Im z < 2\alpha \beta, \\ F^{(1)}_{a,b}(z) & \text{for } 0 < \Im z < \alpha \beta, \end{cases}
\]

defined and continuous on the closure of \( \mathcal{G}_{2,\alpha} \) and analytic for \( z \in \mathcal{G}_{2,\alpha} \). From \[10\] and \[19\] we infer \( F_{a,b}(t) = \omega_\Lambda (\tau_{\tau}(b)) \) and \( F_{a,b}(t+i2\alpha \beta) = \omega_\Lambda (\tau_{\tau}(b)a) \) for \( |t| < \delta_0 \). Analogous results for arbitrary \( n \in \mathbb{N} \) can be established by the same line of arguments but with considerable more effort. \[\Box\]
4 The thermodynamic limit

We will now control the surface energies in the limit \( O_\circ, O, \hat{O} \to \mathbb{R}^4 \). Since we do not have explicit expressions for the surface energies, our approach is quite involved. The first step is to control the convergence of product vectors.

4.1 Consequences of the cluster condition

Let us introduce some notation: Let \( \Lambda = (\mathcal{O}_i^{(i)}, \mathcal{O}^{(i)}, \hat{O}^{(i)}) \) be a sequence of triples of double cones with diameters \( (r_i^{(i)}, r_i^{(i)}, \hat{r}_i^{(i)}) \). We consider the product vectors \( \Omega_p^{(i)} \) and \( \eta_i, \chi_i \in \mathcal{P}^2(\mathcal{M}_\beta(\mathcal{O}_i^{(i)}) \lor \mathcal{M}_\beta(\mathcal{O}^{(i)}), \Omega_\beta) \), which satisfy

\[
(\Omega_p^{(i)} \lor A \Omega_p^{(i)}) = (\Omega_\beta \lor A \Omega_\beta)(\Omega_\beta \lor B \Omega_\beta)
\]

for \( A \in \mathcal{R}_\beta(\mathcal{O}^{(i)}) \) and \( B \in \mathcal{R}_\beta(\hat{O}^{(i)}) \), and

\[
\begin{align*}
(\eta_i \lor MN \eta_i) &= (\Omega_\beta \lor M \Omega_\beta)(\Omega_p^{(i)} \lor N \Omega_p^{(i)}) \\
(\chi_i \lor MN \chi_i) &= (\Omega_\beta \lor M \Omega_\beta)(\Omega_\beta \lor N \Omega_\beta)
\end{align*}
\]

for \( M \in \mathcal{M}_\beta(\mathcal{O}_i^{(i)}) \) and \( N \in \mathcal{M}_\beta(\mathcal{O}^{(i)}) \).

So far there was no restriction on the relative size of the regions \( \mathcal{O}^{(i)} \) and \( \hat{O}^{(i)} \). We will now exploit this freedom: If the net of local observables \( \mathcal{O} \to \mathcal{R}_\beta(\mathcal{O}) \) is regular from the outside, then \( \mathcal{M}_\beta(\mathcal{O})' \cap \mathcal{M}_\beta(\hat{O}) \to \mathcal{O} \otimes \mathcal{O} \). Our aim is to control \( \| \eta_i - \Omega_\beta \| \). The following lemma shows that in order to do so it is sufficient to control \( \| \chi_i - \Omega_\beta \| \).

**Lemma 4.1.** Let \( \{(\mathcal{O}_i^{(i)}, \mathcal{O}^{(i)})\}_{i \in \mathbb{N}} \) be a sequence of pairs of double cones. Then one can find a sequence of double cones \( \{(\hat{O}^{(i)})\}_{i \in \mathbb{N}} \) such that (12) holds true and \( \lim_{i \to \infty} \| \chi_i - \Omega_\beta \| = 0 \).

**Proof.** Consider a sequence of pairs of double cones \( \{(\mathcal{O}_i^{(i)}, \mathcal{O}^{(i)})\}_{i \in \mathbb{N}} \) eventually exhausting all of \( \mathbb{R}^4 \). For each \( i \in \mathbb{N} \) fixed we consider a sequence of double cones \( \{(\hat{O}^{(i,k)})\}_{k \in \mathbb{N}} \) such that \( \hat{O}^{(i,k)} \to \mathcal{O}^{(i)} \) for \( k \to \infty \). In order to ease the notation we set

\[
A_i := \mathcal{M}_\beta(\mathcal{O}_i^{(i)}), \quad B_i := \mathcal{M}_\beta(\mathcal{O}^{(i)}), \quad C_{i,k} := \mathcal{M}_\beta(\hat{O}^{(i,k)}),
\]

\[
D_i := A_i \lor B_i', \quad E_i,k := A_i \lor C_{i,k}'.
\]

For each \( i \in \mathbb{N} \) fixed, the sequence \( \{E_{i,k}\}_{k \in \mathbb{N}} \) of algebras satisfies \( E_{i,k+1} \subset E_{i,k} \) (this follows from \( C_{i,k+1} \subset C_{i,k} \)) and \( \cap_k E_{i,k} = D_i \). Now let \( \Omega_p^{(i,k)} \) denote the unique product vector in the natural positive cone \( \mathcal{P}^2(\mathcal{R}_\beta(\mathcal{O}^{(i)}) \lor \mathcal{R}_\beta(\hat{O}^{(i,k)})', \Omega_\beta) \) satisfying

\[
(\Omega_p^{(i,k)} \lor A \Omega_p^{(i,k)}) = (\Omega_\beta \lor A \Omega_\beta)(\Omega_\beta \lor B \Omega_\beta)
\]

for all \( A \in \mathcal{R}_\beta(\mathcal{O}^{(i)}) \) and \( B \in \mathcal{R}_\beta(\hat{O}^{(i,k)})' \). Note that for \( C_{i,k} \in C_{i,k}' \)

\[
(\Omega_p^{(i,k)} \lor C_{i,k} \Omega_p^{(i,k)}) = (\Omega_\beta \lor C_{i,k} \Omega_\beta).
\]

If we choose product vectors \( \eta_{i,k} \) and \( \chi_i \) in the natural cone \( \mathcal{P}^2(\mathcal{D}_i, \Omega_\beta) \) such that

\[
(\eta_{i,k} \lor MN \eta_{i,k}) = (\Omega_\beta \lor M \Omega_\beta)(\Omega_p^{(i,k)} \lor N \Omega_p^{(i,k)})
\]

and \( (\chi_i \lor MN \chi_i) = (\Omega_\beta \lor M \Omega_\beta)(\Omega_\beta \lor N \Omega_\beta) \) for all \( M \in A_i \) and \( N \in B_i' \), then by a result of Araki [A72]

\[
\| \eta_{i,k} - \chi_i \| \leq \sup_{D_i \in \mathcal{D}_i, \|D_i\|=1} \| (\eta_{i,k} \lor D_i \eta_{i,k}) - (\chi_i \lor D_i \chi_i) \|.
\]
Now assume that for each \( i \in \mathbb{N} \) fixed there exist a sequence \( \{ E_{i,k} \in \mathcal{E}_{i,k} \mid \|E_{i,k}\| = 1\} \) such that

\[
\lim_{k \to \infty} \left( \eta_{i,k}, E_{i,k} \eta_{i,k} \right) - \left( \chi_i, E_{i,k} \chi_i \right) \geq \epsilon_i.
\]

We demonstrate that this leads to a contradiction. The linear functional \( \langle \eta_{i,k} , \cdot \rangle - (\chi_i, \cdot) \) is ultra-weakly continuous on the von Neumann algebra \( D_i \). Therefore the sequence \( \{ E_{i,k} \in \mathcal{E}_{i,k} \mid \|E_{i,k}\| = 1\} \) has a weak limit point \( w - \lim_{k \to \infty} E_{i,k} =: D_i \in D_i = \cap_k \mathcal{E}_{i,k} \) such that

\[
\left| \left( \eta_{i,k}, D_i \eta_{i,k} \right) - \left( \chi_i, D_i \chi_i \right) \right| > \frac{1}{2} \epsilon_i \quad \forall k > k_i
\]

and some \( k_i \in \mathbb{N} \), in contradiction to

\[
\left( \eta_{i,k}, E_{i,k} \eta_{i,k} \right) - \left( \chi_i, E_{i,k} \chi_i \right) = 0 \quad \forall E_{i,k} \in \mathcal{E}_{i,k}, \quad \forall k \in \mathbb{N}.
\]

Therefore, the assumption \(20\) can not hold true. It follows that there exists some \( k_i \in \mathbb{N} \) such that

\[
\sup_{D \in D_i, \|D\| = 1} \left| \left( \eta_{i,k}, D \eta_{i,k} \right) - \left( \chi_i, D \chi_i \right) \right| < \epsilon_i \quad \forall k \geq k_i.
\]

If we set \( \hat{O}^{(i)} := \hat{O}^{(i,k_i)} \), then we can choose \( \epsilon_i \) such that \( \lim_{i \to \infty} \|\chi_i - \eta_i\| = 0 \). \( \square \)

We will now show that the product vector \( \chi \) converges to \( \Omega_\beta \) if \( \mathcal{O}_\alpha \) and \( \mathcal{O} \) tend to \( \mathbb{R}^4 \) and the relative size of \( \mathcal{O}_\alpha \) and \( \mathcal{O} \) obeys the restrictions imposed by the cluster condition.

**Lemma 4.2.** Let \( \{(\mathcal{O}_\alpha^{(i)}, \mathcal{O}^{(i)})\}_{i \in \mathbb{N}} \) denote a sequence of pairs of double cones with diameters \( (r_\alpha^{(i)}, r^{(i)}), i \in \mathbb{N} \). Assume that \( \lim_{i \to \infty} (r_\alpha^{(i)})^d (\delta_\alpha^{(i)})^{-\gamma} = 0 \). It follows that \( \|\chi_i - \Omega_\beta\| \to 0 \) as \( i \to \infty \).

**Proof.** Since \( \chi_i \in \mathcal{P}^4(\mathcal{M}_\beta(\mathcal{O}_\alpha^{(i)}) \vee \mathcal{M}_\beta(\mathcal{O}^{(i)})), \Omega_\beta)) \), we can again rely on the result of Araki [A 74] concerning the distance of two vectors which belong to the natural positive cone \( \mathcal{P}^4(\mathcal{M}_\beta(\mathcal{O}_\alpha^{(i)}) \vee \mathcal{M}_\beta(\mathcal{O}^{(i)})), \Omega_\beta)) \):

\[
\|\chi_i - \Omega_\beta\|^2 \leq \sup_{\|D_i\| = 1} \left| \left( \chi_i, D_i \chi_i \right) - (\Omega_\beta, D_i \Omega_\beta) \right|;
\]

where the supremum has to be evaluated over all elements \( D_i \in \mathcal{M}_\beta(\mathcal{O}_\alpha^{(i)}) \vee \mathcal{M}_\beta(\mathcal{O}^{(i)})) \). Thus \( \lim_{i \to \infty} \|\chi_i - \Omega_\beta\| = 0 \) follows from the cluster condition \(3\) and the assumptions concerning the relative size of \( \mathcal{O}_\alpha \) and \( \mathcal{O} \) stated in the lemma. \( \square \)

Combining Lemma 4.1 and Lemma 4.2 we conclude that \( \lim_{i \to \infty} \|\eta_i - \Omega_\beta\| = 0 \) for an appropriate choice of the relative size of \( \mathcal{O}_\alpha^{(i)}, \mathcal{O}^{(i)} \) and \( \hat{O}^{(i)} \).

### 4.2 Bounds on the quasi-partition function

Let us consider a sequence \( \{\Lambda_i\} = \{(\mathcal{O}_\alpha^{(i)}, \mathcal{O}^{(i)}, \hat{O}^{(i)})\} \) of triples of double cones with diameters \( (r_\alpha^{(i)}, r^{(i)}, \hat{r}^{(i)}) \). In order to ensure that \( \frac{0}{\alpha} < 1/2 \) and \( n \in \mathbb{N} \) fixed) the ‘quasi-partition function’

\[
Z_{\Lambda_i}(\alpha, n) := \text{Tr} \left( E_{\Lambda_i} \Delta^n_{\Lambda_i} E_{\Lambda_i} \right)^n, \quad \Lambda_i = (\mathcal{O}_\alpha^{(i)}, \mathcal{O}^{(i)}, \hat{O}^{(i)}),
\]

is bounded from below as \( i \to \infty \), it is necessary that \( \mathcal{O}^{(i)} \) grows rapidly with \( \mathcal{O}_\alpha^{(i)} \). Otherwise the energy contained in the boundary, which is necessary to decouple the local region from
the outside, lessens the eigenvalues of \( E_{\Lambda_i} \Delta_{p,i}^n E_{\Lambda_i} \) so drastically that it outruns the increase in the number of states contributing to the trace by enlarging \( O_\delta^{(i)} \). Following once again [BjN 89], we will now demonstrate that the condition on the relative size of \( r_0^{(i)} \) and \( r^{(i)} \) which we imposed in order to show that \( \chi_i \) converges to \( \Omega_\beta \) is already sufficient to exclude this possibility.

**Lemma 4.3.** (Buchholz and Junglas). Let \( \{ \Lambda_i \}_{i \in \mathbb{N}} \) be a sequence of triples of increasing space-time regions such that \( \| \eta_i - \Omega_\beta \| \rightarrow 0 \) for \( i \rightarrow \infty \). It follows that \( \mathcal{H}_{\Lambda_i} \) tends to the whole Hilbert space \( \mathcal{H}_\beta \), i.e., \( s - \lim_{i \rightarrow \infty} E_{\Lambda_i} = 1 \).

**Proof.** By assumption \( \eta_i = W_i^* (\Omega_\beta \otimes \Omega_p^{(i)}) \) converges to \( \Omega_\beta \). Therefore the unitary operators \( W_i \) specified in (1) fulfill \( W_i^* (\Phi \otimes \Omega_p^{(i)}) \rightarrow \Phi \) for \( \Phi \in \mathcal{H}_\beta \) as \( i \rightarrow \infty \). Recall that \( E_{\Lambda_i} = W_i^* (\mathbb{1} \otimes P_{\Omega_p^{(i)}}) W_i \), where \( P_{\Omega_p^{(i)}} \) denotes the projection onto \( \mathcal{C} \cdot \Omega_p^{(i)} \). Hence

\[
E_{\Lambda_i} \Phi = W_i^* (\mathbb{1} \otimes P_{\Omega_p^{(i)}}) W_i (\Phi - W_i^* (\Phi \otimes \Omega_p^{(i)})) + W_i^* (\Phi \otimes \Omega_p^{(i)}) \rightarrow \Phi \quad \forall \Phi \in \mathcal{H}_\beta,
\]
as \( i \rightarrow \infty \). I.e., \( s - \lim_{i \rightarrow \infty} E_{\Lambda_i} = 1 \).

**Lemma 4.4.** Let \( \{ (O_\delta^{(i)}, \Omega^{(i)}) \}_{i \in \mathbb{N}} \) denote a sequence of pairs of double cones with diameters \( (r_0^{(i)}, r^{(i)}) \), \( i \in \mathbb{N} \). Assume that \( \lim_{i \rightarrow \infty} (r_0^{(i)})^\delta (\delta_0^{(i)})^{-\gamma} = 0 \). It follows that

\[
\lim_{i \rightarrow \infty} \text{Tr} \left( E_{\Lambda_i} \Delta_{p,i}^n E_{\Lambda_i} \right)^n > 0 \quad \forall n \in \mathbb{N}.
\]

**Proof.** By definition, \( \Delta_{p,i}^{1/2} \) is a positive operator. The vector \( \Omega_p^{(i)} \) is the unique eigenvector of \( H_p \) for the simple eigenvalue \( \{ 0 \} \). Let \( \{ \Omega_\beta, \Psi_1, \Psi_2, \ldots \} \) be an orthonormal basis in \( \mathcal{H}_\beta \) and set \( \Gamma^{(i)}_j = W_i^* (\Psi_j^{(i)} \otimes \Omega_p) \in \mathcal{H}_\beta \). For \( 0 < \alpha < 1/2 \) and \( j \in \mathbb{N} \) this implies that \( (\Gamma^{(i)}_j, \Delta_{p,i}^\alpha \Gamma^{(i)}_j) = (\Psi_j, \Delta^{2\alpha} \Psi_j) (\Omega_p, \Omega_p) > 0 \). Since \( s - \lim_{i \rightarrow \infty} E_{\Lambda_i} = 1 \), it follows that

\[
\lim_{i \rightarrow \infty} \text{Tr} \left( E_{\Lambda_i} \Delta_{p,i}^\alpha E_{\Lambda_i} \right)^2 \geq \lim_{i \rightarrow \infty} \sum_{j=1}^{\infty} \left( E_{\Lambda_i} \Gamma^{(i)}_j, \Delta_{p,i}^\alpha E_{\Lambda_i} \Delta_{p,i}^\alpha E_{\Lambda_i} \Gamma^{(i)}_j \right)
= \lim_{i \rightarrow \infty} \sum_{j=1}^{\infty} \left( \Delta_{p,i}^\alpha \Gamma^{(i)}_j, E_{\Lambda_i} \Delta_{p,i}^\alpha \Gamma^{(i)}_j \right)
= \lim_{i \rightarrow \infty} \sum_{j=1}^{\infty} (\Psi_j, \Delta^{2\alpha} \Psi_j) > 0.
\]

\[
\square
\]

### 4.3 Commutator estimates

The unit ball in \( \mathcal{A}^* \) is weak*-compact. Thus for every net of states \( \Lambda(\mathcal{O}_0, \mathcal{O}, \hat{O}) \rightarrow \omega_\Lambda \), there exists a subnet of \( \{ \omega_{\Lambda_i} \}_{i \in I} \) converging to some state \( \omega \). Whether or not this state is a \( (\tau, n, \alpha/\beta) \)-KMS state depends on the energy contained in the boundary, i.e., the choice of the relative size of \( \mathcal{O}_0^{(i)}, \mathcal{O}^{(i)} \) and \( \hat{O}^{(i)} \). We show that the necessary quantitative information restricting the surface energy can be drawn from the bounds on the nuclear norm of the map \( \Theta_{n,\mathcal{O}} \) introduced in [B] and the cluster condition [E].
Let \( \{ \Lambda_i = (\mathcal{O}^{(i)}, \mathcal{O}^{(i)}, \hat{O}^{(i)}) \}_{i \in \mathbb{N}} \) be a sequence\(^5\) of triples of double cones with diameters \( (r_0^{(i)}, r^{(i)}, \hat{r}^{(i)}) \), \( i \in \mathbb{N} \). We will now exploit the fact that the elements of \( \mathcal{A}_p \), \( p \in \mathbb{N} \), introduced at the end of Subsection 2.2, have good localization properties in space-time: we will show that there exists some \( p \in \mathbb{N} \) such that

\[
|\omega_{\Lambda_i}(a \tau_{i\alpha \beta}(b)) - \omega_{\Lambda_i}(ba)| < \epsilon_i \quad \forall a, b \in \mathcal{A}_p,
\]

where \( \epsilon_i \searrow 0 \) as \( i \to \infty \). Thus the surface energy can be controlled by adjusting the relative size of \( r_0^{(i)}, r^{(i)} \) and \( \hat{r}^{(i)} \).

Inspecting the definition \( \omega_{\Lambda_i} \) of \( \omega_{\Lambda} \), we recognize that in order to prove (21) it is sufficient to control

\[
\Tr \rho_{\Lambda_i} \pi_{\beta}(a) \pi_{\beta}(\tau_{i\alpha \beta}(b)), E_{\Lambda_i} \bigg]\frac{\Tr \pi_{\beta}(\tau_{2i\alpha \beta}(b)), E_{\Lambda_i} \cdot (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2 \pi_{\beta}(a)}{\Tr (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2} \leq \frac{\| \pi_{\beta}(\tau_{2i\alpha \beta}(b) - d_i), E_{\Lambda_i} \| \cdot \Tr (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2 \cdot \| a \|}{\Tr (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2} \leq \frac{2\| a \|}{\Tr (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2} \| \tau_{2i\alpha \beta}(b) - d_i \| \cdot (\Tr (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2).
\]

Here \( d_i \in \mathcal{A}(\mathcal{O}^{(i)}) \) denotes a local approximation of \( d := \tau_{i2\alpha \beta}(b) \in \mathcal{A}_p \) which satisfies \( [E_{\Lambda_i}, d_i] = 0 \). Thus

\[
\bigg|\Tr \rho_{\Lambda_i} \pi_{\beta}(a) \pi_{\beta}(\tau_{i\alpha \beta}(b)), E_{\Lambda_i} \bigg| \leq \frac{c_1}{\Tr (\Delta_{p,i}^{\alpha \beta}, E_{\Lambda_i})^2} \cdot e^{-c_2(r_0^{(i)})^{2p}} \cdot e^{c_3(r^{(i)})^d}
\]

for certain positive constants \( c_1 = 2C \| a \|, c_2 = \kappa/(2^{2p}) \) and \( c_3 = 2c(\alpha^{-m} + (1/2 - \alpha)^{-m}) \), where \( m > 0 \). In the last inequality we made use of Proposition 3.3 and the second part of Lemma 2.1. Inspecting the r.h.s. of (22) closely, we find that the numerator vanishes in the limit \( i \to \infty \), if \( \exp(-c_2(r_0^{(i)})^{2p}) \cdot \exp(c_3(r^{(i)})^d) \) goes to zero as \( i \to \infty \). As has been shown in the previous section, the denominator does not vanish as \( i \to \infty \), but is bounded from below by some positive constant, if \( \lim_{i \to \infty} (r_0^{(i)})^d(\delta_0^{(i)})^{-\gamma} = 0 \).

In other words, the distance \( \delta_0^{(i)} \) has to grow sufficiently fast such that \( \eta_i \to \Omega_\beta \), and \( p \) has to be chosen sufficiently large such that the elements in \( \mathcal{A}_p \) are sufficiently well localized to fulfill the boundary condition (3.2) up to some small error term.

We will now establish the KMS property for all weak limit points of \( \{ \omega_{\Lambda} \} \), provided the regions \( \Lambda_i = (\mathcal{O}_0^{(i)}, \mathcal{O}^{(i)}, \hat{O}^{(i)}) \) tend to the whole space-time in agreement with the restrictions imposed on the relative size of \( r_0^{(i)}, r^{(i)} \) and \( \hat{r}^{(i)} \).

**Theorem 4.5.** Assume that both the nuclearity condition (2) and the cluster condition (3) hold. Then there exists a choice of triples of space-time regions \( \Lambda_i \) such that every weak limit point of the (generalized) sequence \( \{ \omega_{\Lambda_i} \}_{i \in \mathbb{I}} \) is a \( \tau \)-KMS state at temperature \( 1/\beta' > 0 \).

\(^5\)Note that it is sufficient to work with sequences if the operators \( a \) and \( b \) appearing in (21) are fixed.
Proof. Let \( n \in \mathbb{N} \) and \( 0 < \alpha < 1/2 \) be fixed such that \( \beta' = n\alpha\beta \). Moreover, let \( \Lambda_i = (\mathcal{O}_i^{(i)}, \mathcal{O}^{(i)}, \hat{\mathcal{O}}^{(i)}) \) be a sequence of triples of double cones with diameters \( r_0^{(i)}, r^{(i)} \) and \( \hat{r}^{(i)} \) such that \( \lim_{i \to \infty} (r_0^{(i)})^d (\delta_0^{(i)})^{-\gamma} = 0 \) and \( \hat{\mathcal{O}}^{(i)} \searrow \mathcal{O}^{(i)} \) sufficiently fast as \( i \to \infty \) such that \( \lim_{i \to \infty} \|r_i - \Omega_\beta\| = 0 \).

Let us recall: the nuclearity condition fixes the constants \( d \) and \( m \) and the cluster condition fixes the constants \( d' \) and \( \gamma \). We will now fix \( p \in \mathbb{N} \). Taking into account the restrictions on the relative size of \( r_0^{(i)} \) and \( r^{(i)} = r_0^{(i)} + 2\delta_0^{(i)} \) imposed by the cluster condition [3]—it is sufficient that \( (r_0^{(i)})^d (\delta_0^{(i)})^{-\gamma} \) goes to zero as \( i \) goes to infinity—we can now chose \( p \) such that \( \exp(-c_2 r_0^{(i)})^{2p} \cdot \exp(c_3 (r^{(i)})^d) \) goes to zero as \( i \to \infty \).

Let \( a, b \in \mathcal{A}_p \) and consider the case \( n = 2 \).

i.) Let \( \omega_{2\alpha\beta} \) denote the limit state of a convergent subnet \( \{\omega_{I_i}\}_{i \in I} \). For every \( \epsilon > 0 \) we can find an index \( i \in I \) such that

\[
|\omega_{2\alpha\beta}(a_\tau_{2\alpha\beta}(b) - ba)| \leq |\omega_{I_i}(a_\tau_{2\alpha\beta}(b) - ba)| + \epsilon.
\]

ii.) We now approximate \( \tau_{2\alpha\beta}(b) \), \( \tau_{2\alpha\beta}(b) \) and \( b \) by local elements in \( \mathcal{A}(\mathcal{O}_5^{(i)}) \) and apply the commutator estimate \( 22 \) several times: for suitable (large) \( i \in \mathbb{N} \) we find

\[
|\omega_{2\alpha\beta}(a_\tau_{2\alpha\beta}(b) - ba)| \leq \left| \frac{\text{Tr} \pi_\beta(a_{\tau_2_{2\alpha\beta}}(b)) (E_{\Lambda, \Delta_{\mu}^2} E_{\Lambda})^2}{\text{Tr} (\Delta_{\mu}^2 E_{\Lambda})^2} - \omega_{\Lambda_i}(ba) \right| + \epsilon
\]

\[
\leq \left| \frac{\text{Tr} \pi_\beta(a) E_{\Lambda, \pi_\beta(\tau_{2\alpha\beta}(b))} (\Delta_{\mu}^2 E_{\Lambda})^2}{\text{Tr} (\Delta_{\mu}^2 E_{\Lambda})^2} - \omega_{\Lambda_i}(ba) \right| + 2\epsilon
\]

\[
= \left| \frac{\text{Tr} \pi_\beta(a) E_{\Lambda, \Delta_{\mu}^2 \pi_\beta(\tau_{2\alpha\beta}(b))} (\Delta_{\mu}^2 E_{\Lambda})^2}{\text{Tr} (\Delta_{\mu}^2 E_{\Lambda})^2} - \omega_{\Lambda_i}(ba) \right| + 2\epsilon
\]

\[
\leq \left| \frac{\text{Tr} \pi_\beta(a) (E_{\Lambda, \Delta_{\mu}^2})^2 \pi_\beta(b) E_{\Lambda}}{\text{Tr} (\Delta_{\mu}^2 E_{\Lambda})^2} - \omega_{\Lambda_i}(ba) \right| + 3\epsilon
\]

\[
\leq \left| \frac{\text{Tr} \pi_\beta(a) (E_{\Lambda, \Delta_{\mu}^2})^2 \pi_\beta(b) E_{\Lambda}}{\text{Tr} (\Delta_{\mu}^2 E_{\Lambda})^2} - \omega_{\Lambda_i}(ba) \right| + 4\epsilon
\]

\[
= 4\epsilon.
\]

Thus \( \omega_{2\alpha\beta}(a_\tau_{2\alpha\beta}(b)) = \omega_{2\alpha\beta}(ba) \) for all \( a, b \in \mathcal{A}_p \). Now recall that \( \mathcal{A}_p \) (for each \( p \in \mathbb{N} \)) is a \( \tau \)-invariant *-subalgebra of the set \( \mathcal{A}_\tau \) of analytic elements of \( \mathcal{A} \) with respect to \( \tau \). Consequently, \( \omega_{2\alpha\beta} \) is a \((\tau, 2\alpha\beta)\)-KMS state.

Similar results for arbitrary \( n \in \mathbb{N} \) can be established by the same line of arguments but with considerable more effort.

Once we have constructed a \((\tau, \beta')\)-KMS state \( \omega_{\beta'} \), the GNS-representation \( \pi_{\beta'} \) leads to a new thermal field theory

\[
\mathcal{O} \to \mathcal{R}_{\beta'}(\mathcal{O}) := \pi_{\beta'}(\mathcal{A}(\mathcal{O}))'' \quad \mathcal{O} \in \mathbb{R}^4,
\]

acting on a new Hilbert space \( \mathcal{H}_{\beta'} \) with GNS-vector \( \Omega_{\beta'} \). If \( \beta \neq \beta' \), then the new thermal field theory will not be unitarily equivalent to the old one [4]. In fact, there might even be several extremal \((\tau, n\alpha\beta)\)-KMS states, which induce unitarily inequivalent representations, i.e., “disjoint thermal field theories”, at the same temperature \( 1/\beta' = (n\alpha\beta)^{-1} \).

21
Acknowledgements. The present work started in collaboration with D. Buchholz. The final formulation is strongly influenced by his constructive criticism and by several substantial hints. Kind hospitality of the II. Institute for theoretical physics, University of Hamburg, the Institute for theoretical physics, University of Vienna, the Erwin Schrödinger Institute (ESI), Vienna, and the Dipartimento di Matematica, Universita di Roma “Tor Vergata” is gratefully acknowledged. This work was financed by the Fond zur Förderung der Wissenschaftlichen Forschung in Austria, Proj. Nr. P10629 PHY and a fellowship of the Operator Algebras Network, EC TMR-Programme.
