Quantifying asymmetry of anterior cerebral arteries as a predictor of anterior communicating artery complex aneurysm

Arjun Burlakoti 1, Jaliya Kumaratilake,2 David J Taylor,3 Maciej Henneberg4

ABSTRACT

Objectives The aim of this study was to establish an anatomical index for early prediction of the risk of development of aneurysms in anterior communicating arterial complex (AcomAC). The asymmetric diameter of one anterior cerebral artery (ACA) to other could alter haemodynamics and may contribute to formation of aneurysms in AcomAC and be a reliable predictor of the risk of development of aneurysms.

Design and setting This is a retrospective, observational and quantitative study, which used cerebral computed tomography angiography (CCTA) scans in South Australia.

Participants CCTA scans of 166 adult patients of both sexes were studied.

Main outcome measures The internal diameters of the proximal segments of ACAs (A1s) were measured. Position and presence or absence of aneurysms in AcomAC were determined. The ratio of A1 diameters was taken as a measure of A1 asymmetry.

Results The ratio of diameters of A1s correlated with the occurrence of AcomAC aneurysms. The risk of development of aneurysms in AcomAC was much greater (80%, OR=47.3) when one A1 segment’s radius was at least 50% larger (ie, 2.25 times cross-sectional area) than the other.

Conclusion The general information on asymmetric A1 has been published previously. The present findings have significant contribution since the A1s asymmetry ratios have been categorised in ascending order and matched with the presence of AcomAC aneurysms. The asymmetry ratio of the A1 is a good predictor for the development of AcomAC aneurysms. Reconstruction of the asymmetric A1 could be done if the technology gets advanced.

INTRODUCTION

Rupture of cerebral aneurysms causes subarachnoid haemorrhages (SAH) leading to high mortality and morbidity. The incidence of SAH has been 10–36 per 100,000 people per year and about 3/4 of them resulted from spontaneous rupture of cerebral aneurysms.1 2 Large cerebral aneurysms may also compress adjacent cranial nerves.3 The mortality and morbidity rates resulting from ruptured cerebral aneurysms remain high, with around one-third dying at the time, one-third suffering a major stroke and one-third making a reasonable recovery.4 An aneurysm is a dilatation and outpouching of the wall of a blood vessel.5 6 The action of fluctuating blood pressure on vascular walls has been identified as the main cause for the development of aneurysms.7 The risk of aneurysm rupture is 6–8 in 100,000 per year in most developed countries.8 In South Australia, where the total population is 1.7 millions, radiologists involved in the treatment observed approximately 170 ruptured aneurysm cases per year (ie, 1 in every 10,000 cases per year). Another study revealed that about 1 in 30 adults likely to have intracranial aneurysms and in 25% of them, the aneurysms could rupture and produce SAHs or compression of surrounding structures.9 Anterior communicating artery complex (AcomAC) has been the most common

Key messages

What is already known about this subject?

► Relationship of asymmetry of A1 segment of anterior cerebral artery (ACA) to the occurrence of aneurysms in anterior communicating arterial complex (AcomAC) has been observed in literature but has not been explained nor quantified.

What are the new findings?

► Asymmetry of the A1 of ACA was quantified, and a mathematical model has been established to predict the likelihood of developing AcomAC aneurysms depending on the degree of asymmetry.

How might these results affect future research or surgical practice?

► Patients with asymmetry of A1 found in their brain scans should be closely followed up, because of the high risk of developing aneurysms in the AcomAC complex. Reconstruction of the asymmetric A1 can be done to prevent the development of AcomAC aneurysms, if ethically justified.

location of ruptured cerebral aneurysms.\textsuperscript{9} Unruptured aneurysms have been observed in 2.8\% of patients investigated by magnetic resonance (MR) angiography.\textsuperscript{10} People with variations in cerebral arteries, particularly, in anterior cerebral arterial (ACA) territory are thought to be subjected to imbalance in cerebral blood flow leading to cerebrovascular pathologies, including cerebral aneurysms.\textsuperscript{11}

Variations in cerebral basal arterial network have ranged from missing arterial segments to asymmetry between collateral arterial segments and the later was more common.\textsuperscript{12,13} Some of the most variant and asymmetric patterns of arteries were seen in relation to anterior cerebral and anterior communicating arterial territories.\textsuperscript{11,14} Fluctuation in arterial blood flow, and thus the blood pressure, has been observed in asymmetric A1 segments.\textsuperscript{15,16} Such variations in blood flow could predispose the arterial wall for aneurysmal dilatations.\textsuperscript{17–22} Genetics, smoking, trauma and medications are factors that could weaken the walls of arteries and predispose them to the development of aneurysms, particularly when subjected to alteration in haemodynamics or chronic hypertension.\textsuperscript{22} Prediction and early detection of aneurysms allow treatment, thus could prevent or reduce the incidences of cerebral stroke, including reoccurrences of aneurysms. The aim of this research was to investigate the relationship of asymmetry between A1s and the development of AcomAC aneurysms. As far as we know, no studies have been done on quantifying and calculating the degree of A1 asymmetry to the occurrences of AcomAC aneurysms. A method to predict the risk of occurrence of aneurysms in AcomAC using the degree of asymmetry between right and left A1s has been established.

METHODS

Study design

Internal diameters of A1s were measured on cerebral CT angiography (CCTA) digital images obtained from 166 (80 males and 86 females) adult individuals (average age=60 years, SD=16) (see online supplemental file 1). The same images were used to determine the presence or the absence of AcomAC aneurysms. The source of the CCTA images were the Carestream (Vue RIS V.11.0.14.35) database of the Royal Adelaide Hospital (RAH), University of Adelaide, South Australia. The CCTA images were taken between January 2011 and December 2018. Patient’s personal details have not been copied, documented or included in this research.

The CCTA images studied were those taken for the clinical investigation of different cranial pathologies. These included 51 cases out of 166 patients who had a history of previously diagnosed cerebral aneurysms (see online supplemental file 1).

Data collection and extraction

Data collection was carried out by the corresponding author in consultation with radiologists from the RAH.
severe asymmetry $\geq 2$, (table 2 and online supplemental file 3). The rationale for this classification was for easy application and interpretation. The diameter (and hence also the radius) ratio of 1.5 corresponds to the 2.25 times difference in the cross-sectional area of the vessel’s lumen, while the ratio of 2.0 reflects four times difference in the cross-sectional area of the vessel lumen.

STATISTICAL ANALYSIS
A cross-sectional observational design and SPSS V.25 (IBM) program were used in the study. Measurement error analysis has been described in table 1. In the main analysis, non-parametric statistics ($\chi^2$) were used and ORs were calculated to observe the strength of association between the A1 asymmetries and the AcomAC aneurysms (table 2 and online supplemental file 3).

RESULTS
The asymmetry ratios of right and left A1 segments of ACA together with the presence and absence of AcomAC aneurysms are presented in table 2, and online supplemental files 1 and 3 (in ascending order, n=166). Among 141 patients with mild to moderate A1 asymmetry ($\leq 1.5$), 11 had AcomAC aneurysms. Out of 13 patients with substantial asymmetry ($>1.5$ to $\leq 2.0$), 10 had AcomAC aneurysms. In 12 patients with severe type of asymmetric ratios ($>2.0$), 10 were affected with AcomAC aneurysms.

| Table 1 Accuracy and reliability of the measurements of the first part of the anterior cerebral artery (A1) in cerebral CT angiography (CTA) scans |
|--------------------------------------------------|--|-------------------|--|-------------------|
| Repeat A1 measurement in axial CTA images (not adjusted*) | 0.93 | 0.24 | 11.00 |
| Repeat A1 measurement in axial CTA images (adjusted*) | 0.98 | 0.12 | 5.39 |
| Repeat A1 measurement in axial and coronal CTA images (adjusted*) | 0.98 | 0.10 | 4.77 |
| Repeat A1 measurement in coronal CTA images (not adjusted) | 0.94 | 0.22 | 10.45 |
| Repeat A1 measurement in coronal CTA images (adjusted*) | 0.96 | 0.14 | 6.55 |

The coefficients of variation of the measurements (rTEM) are presented. Reliability is the correlation among the previous first measurement done in coronal and axial CTA slices and the second measurement performed in axial and coronal cerebral CTA after 15 months of the initial measurement taken of the same artery, computed tomography = CT, A1=first part of anterior cerebral artery, n=30 *Adjustment made by excluding two outliers from the previous and the corresponding repeat measurements of right A1 (file supplied in online supplemental file 2).

n=166, without history of aneurysms (n=115), with the previous history of aneurysm (n=51). A1 ACA, first segment of the anterior cerebral artery; AcomA, anterior communicating artery.
Among the people with A1 asymmetry ratios of less than 1.5 just 7.8% had aneurysms while in those with ratios of >1.5 to ≤2 and >2, the risks of developing AcomAC aneurysm were 77% and 83%, respectively. In summary, patients with asymmetry ratios greater than 1.5 had 80% risk of developing aneurysms (OR=47.3), while those with asymmetry ratios below 1.5 had 7.8% AcomAC aneurysms (OR=0.02), (table 2, online supplemental files 1, 3 and 4).

The chances of developing AcomAC aneurysms in the presence of substantial and severe A1 asymmetries were statistically similar between people with or without a previous history of aneurysms (table 2 and online supplemental file 3). In patients with no previous history of aneurysms (n=115), the incidences, risks and ORs (table 2 and online supplemental file 3) of AcomAC aneurysms were similar to the entire sample and to the patients with previous history of aneurysm.

The prevalence of AcomAC aneurysms between sexes and among age groups was statistically not different. Altogether, 31 out of 166 cases had AcomAC aneurysms and 77 out of 166 cases had cerebral aneurysms elsewhere (ie, other than the AcomAC aneurysm). Seven out of 11 cases with AcomAC aneurysms that had only mild asymmetry of A1 also had aneurysms elsewhere in the brain other than AcomAC location (table 3). However, there was no significant relationship between the presence of AcomAC aneurysms and aneurysms elsewhere in the brain ($\chi^2$ 3.7, p=0.05). Furthermore, statistical relationship between A1 asymmetry ratio and the presence of cerebral aneurysms elsewhere was not found (p=0.05). All patients with AcomAC aneurysms had 1.66 median asymmetry ratio, while the patients without the presence of AcomAC aneurysms had 1.09 median asymmetry ratio. The median A1 asymmetry ratio for all the cases included in this study was just 1.10 (table 3, online supplemental files 1 and 3).

### DISCUSSION

The current study quantified for the first time, A1 asymmetry and the likelihood of occurrences of AcomAC aneurysms. Previously the co-occurrence of AcomAC aneurysms with A1 asymmetry has been observed but not quantified.\(^ {11,25,26} \) The study included random CCTA cases accessing the data at a specialised tertiary centre. Obviously, we would assume to see cases of suspected cerebral pathologies in a specialised tertiary medical centre. We examined fairly a large number of 166 CTA evaluating individual A1 asymmetry and aneurysms. The findings (OR and risk percentage) on A1 asymmetry ratio ($\geq$ 1.42) were extremely significant in relation to the AcomAC aneurysms.

The findings of the study indicate that, the prevalence of aneurysms in AcomAC was greater with increasing asymmetry between left and right A1s (table 2 and online supplemental file 3). The asymmetry ratio of 1.5 indicates that the cross-sectional area of an A1 segment is twice as large as that of the other one ($1.5^2=2.25$). Furthermore, such asymmetry would likely to have significant haemodynamic effects that could produce 80% risk of AcomAC aneurysms (table 2, online supplemental file 3 and online supplemental file 4). The exact mechanism involved in causing aneurysms in AcomAC is not well understood.\(^ {27} \) The development of aneurysm could be due to the altered haemodynamics resulting from the increased blood flow and the greater peak systolic pressure in the larger ACA.\(^ {12,27,28} \) Imbalanced haemodynamics originating from the larger ACA may weaken and dilate the wall of the AcomAC at branching points, resulting in an

n=166; without history of aneurysms, n=115; and with the previous history of aneurysm, n=51.
aneurysmal formation.\textsuperscript{12, 21, 29} Thus, the extent of the asymmetry in A1s may allow to predict the occurrence of the AcomAC aneurysms. Current sample included patients presenting with various cerebral problems, including strokes and aneurysms. However, when patients were divided into two subsamples: those with a history and without known history of aneurysms, the results did not differ significantly between these sub samples (table 2 and online supplemental file 3). This lack of difference indicates that prior history of aneurysms did not influence the overall results of the study. Therefore, the observed correlation between asymmetry of A1s and AcomAC aneurysms is independent of the prior history of any cerebral aneurysms, because in the current sample there is no correlation between presence of AcomAC aneurysms and aneurysms elsewhere ((table 2 and online supplemental file 3).

The A1 asymmetry ratio was just below 1.5 in 11 out of 31 AcomAC aneurysms cases. However, 3 out of those 11 cases had A1 asymmetry ratios of more than 1.42 (indicating double the cross-sectional area of one A1 artery compared with the other). Furthermore, all others (ie, 8 out of those 11 cases with asymmetry ratio below 1.5) had asymmetry ratios above the median of 1.09 and represented the ‘mild to moderate asymmetry’ category. Seven of those 11 cases had also aneurysms elsewhere (tables 2 and 3 and online supplemental file 3). These may indicate that causes for the development of AcomAC aneurysms in the lower A1 asymmetry (<1.40) cases may be because of the quality of vessel’s walls and high blood pressure, in addition to altered haemodynamics resulting from the asymmetry.

Since the CCTA data were taken from the specialised medical centre, it is true that we get to see symptomatic individuals with different pathologies. That approach is even better to see the connection between A1 asymmetry and the presence or absent of aneurysms rather than trying to scan many innocent people in the community, exposing them to the radiation unnecessarily. Modifiable known risk factors, such as history of smoking and hypertension were not quantified in this study. These could have been supplementary factors promoting AcomAC aneurysms, however, literature suggests hypertension is not related to the cerebral aneurysms.\textsuperscript{30} Furthermore, there is no reason to assume that A1 asymmetry is related to the smoking and hypertension. This research found a coincidence of A1 asymmetry and AcomAC aneurysms. This coincidence could result from: (A) AcomAC aneurysm altering the blood flow and remodelling the size of A1 segments, (B) Asymmetry of A1 arteries causing altered blood flow in AcomAC and affecting the walls and producing the aneurysm. Remodelling of the size of arteries in the vicinity or proximal to an aneurysm is not known, therefore, it is more likely that A1 asymmetry causes aneurysms. A longitudinal prospective study would likely confirm vessel asymmetry as the cause of aneurysms rather than the reverse. We are not aware of such a study being conducted and there may be significant ethical impediments. Treatment and the management of patients after strokes are costly to the affected family as well as to the country. A multinational study has shown that, the cost of management of a patient after a stroke ranged from US$18 538–US$228 038.\textsuperscript{31} The procedure of treatment of unruptured aneurysms is safe, and the risk of development of stroke is approximately 3% and the mortality is less than 1%, therefore, there is great advantage in identifying and treating aneurysms before they rupture.\textsuperscript{32, 33}

The ability to predict the likelihood of the development of aneurysms in AcomAC using the asymmetry ratio between right and left A1s could enhance the viability of a national screening programme.

Undertaking CCTA screening in the general population is not recommended due to ethical reason. However, if A1 asymmetry is noticed in cranial investigation done for other reasons, clinicians should be cautious as it could indicate the possibility of future development of aneurysms. Therefore, MRI screening of older individuals may be beneficial, and has been recommended.\textsuperscript{20} These findings make significant contribution to existing knowledge, since the A1 asymmetry index has been categorised in ascending order and matched with the presence or absence of AcomAC aneurysms in each of the 166 cases. This type of study has not been done before. General anatomical variations of A1 could be corrected with the advancement of medical and surgical technologies. This would prevent unequal blood flow and pressure contributing to the occurrences of AcomAC aneurysms. Patients who have A1 asymmetry (especially the A1 asymmetry with ≥1.42) on scans should be monitored regularly by follow up imaging and angiograms. Reconstruction of A1 asymmetry is a future possibility with technological advancement.

**CONCLUSION**

The asymmetry of the diameters of A1s should be routinely assessed in all patients undergoing cerebral imaging, which includes these vessels. Patients with asymmetry of the A1 should be closely followed up, because of the high risk of development of aneurysms in the AcomAC complex. Reconstruction of the asymmetric A1 could be done if the technology gets advanced in the future.
