GAUSSIAN PSEUDO-MAXIMUM LIKELIHOOD ESTIMATION OF FRACTIONAL TIME SERIES MODELS

BY JAVIER HUALDE\(^1\) AND PETER M. ROBINSON\(^2\)

Universidad Pública de Navarra and London School of Economics

We consider the estimation of parametric fractional time series models in which not only is the memory parameter unknown, but one may not know whether it lies in the stationary/invertible region or the nonstationary or non-invertible regions. In these circumstances, a proof of consistency (which is a prerequisite for proving asymptotic normality) can be difficult owing to nonuniform convergence of the objective function over a large admissible parameter space. In particular, this is the case for the conditional sum of squares estimate, which can be expected to be asymptotically efficient under Gaussianity. Without the latter assumption, we establish consistency and asymptotic normality for this estimate in case of a quite general univariate model. For a multivariate model, we establish asymptotic normality of a one-step estimate based on an initial \(\sqrt{n}\)-consistent estimate.

1. Introduction. Autoregressive moving average (ARMA) models have featured prominently in the analysis of time series. The versions initially stressed in the theoretical literature (e.g., [11, 26]) are stationary and invertible. Following [6], unit root nonstationarity has frequently been incorporated, while “overdifferenced” noninvertible processes have also featured. Stationary ARMA processes automatically have short memory with “memory parameter,” denoted \(\delta_0\), taking the value zero, implying a huge behavioral gap relative to unit root versions, where \(\delta_0 = 1\). This has been bridged by “fractionally-differenced,” or long memory, models, a leading class being the fractional autoregressive integrated ARMA (FARIMA). A FARIMA \((p_1, \delta_0, p_2)\) process \(x_t\) is given by

\[
\begin{align*}
    x_t &= \Delta^{-\delta_0} \{ u_t 1(t > 0) \}, & t &= 0, \pm 1, \ldots, \\
    \alpha(L) u_t &= \beta(L) \varepsilon_t, & t &= 0, \pm 1, \ldots,
\end{align*}
\]

Key words and phrases. Fractional processes, nonstationarity, noninvertibility, Gaussian estimation, consistency, asymptotic normality, multiple time series.

3152
where \( \{x_t\} \) is the observable series; \( L \) is the lag operator; \( \Delta = 1 - L \);

\[
(1 - L)^{-\zeta} = \sum_{j=0}^{\infty} a_j(\zeta)L^j, \quad a_j(\zeta) = \frac{\Gamma(j + \zeta)}{\Gamma(\zeta)\Gamma(j + 1)}
\]

with \( \Gamma(\zeta) = \infty \) for \( \zeta = 0, -1, \ldots \), and by convention \( \Gamma(0)/\Gamma(0) = 1 \); \( \mathbb{1}(\cdot) \) is the indicator function; \( \alpha(L) \) and \( \beta(L) \) are real polynomials of degrees \( p_1 \) and \( p_2 \), which share no common zeros, and all of their zeros are outside the unit circle in the complex plane; and the \( \varepsilon_t \) are serially uncorrelated and homoscedastic with zero mean. The reason (1.1) features the truncated process \( u_t \mathbb{1}(t > 0) \) rather than simply \( u_t \) is to simultaneously cover \( \delta_0 \) falling in both the stationary region (\( \delta_0 < \frac{1}{2} \)) and the nonstationary region (\( \delta_0 \geq \frac{1}{2} \), where otherwise the process would "blow up"). In the former case, the truncation implies that \( x_t \) is only "asymptotically stationary." In recent years, fractional modeling has found many applications in the sciences and social sciences; for example, with respect to environmental and financial data.

Early work on asymptotic statistical theory for fractional models assumed \( \delta_0 < \frac{1}{2} \) [and replaced \( u_t \mathbb{1}(t > 0) \) by \( u_t \) in (1.1)]. Assuming \( \delta_0 \in (0, \frac{1}{2}) \), [8–10] and [12] showed consistency and asymptotic normality of Whittle estimates (of \( \delta_0 \) and other parameters, such as the coefficients of \( \alpha \) and \( \beta \)), thereby achieving analogous results to those of [11, 26] for stationary ARMA processes [i.e., (1.2) with \( u_t = x_t \)] and other short memory models. More recently, [16] considered empirical maximum likelihood inference covering this setting. Note that [8–10] and [12], and much other work, not only excluded \( \delta_0 \geq \frac{1}{2} \) but also the short-memory case \( \delta_0 = 0 \), as well as negatively dependent processes where \( \delta_0 < 0 \). To some degree, other \( \delta_0 \) can be covered, for example, for \( \delta_0 \in (1, 3/2) \) one can first-difference the data, apply the methods and theory of [8–10] and [12], and then add 1 to the memory parameter estimate, but this still requires prior knowledge that \( \delta_0 \) lies in an interval of length no more than \( \frac{1}{2} \).

On the other hand, [3] argued that the same desirable properties should hold without so restricting \( \delta_0 \), in case of a conditional-sum-of-squares estimate, and this would be consistent with the classical asymptotic properties established by [18] for score tests for a unit root and other hypotheses against fractional alternatives, by comparison with the nonstandard behavior of unit root tests against stationary autoregressive alternatives. However, the proof of asymptotic normality in [3] appears to assume that the estimate lies in a small neighborhood of \( \delta_0 \), without first proving consistency (see also [24]). Due to a lack of uniform convergence, consistency of this implicitly-defined estimate is especially difficult to establish when the set of admissible values of \( \delta \) is large. In particular, this is the case when \( \delta_0 \) is known only to lie in an interval of length greater than \( \frac{1}{2} \). In the present paper, we establish consistency and asymptotic normality when the interval is arbitrarily large, including (simultaneously) stationary, nonstationary, invertible and noninvertible values of \( \delta_0 \). Thus, prior knowledge of which of these phenomena obtains
is unnecessary, and this seems especially practically desirable given, for example, that estimates near the $\delta_0 = \frac{1}{2}$ or $\delta_0 = 1$ boundaries frequently occur in practice, while empirical interest in autoregressive models with two unit roots suggests allowance for values in the region of $\delta_0 = 2$ also, and (following [2]) antipersistence and the possibility of overdifferencing imply the possibility that $\delta_0 < 0$.

We in fact consider a more general model than (1.1), (1.2), retaining (1.1) but generalizing (1.2) to

$$ u_t = \theta(L; \varphi_0)\varepsilon_t, \quad t = 0, \pm 1, \ldots, $$

where $\varepsilon_t$ is a zero-mean unobservable white noise sequence, $\varphi_0$ is an unknown $p \times 1$ vector, $\theta(s; \varphi) = \sum_{j=0}^{\infty} \theta_j(\varphi) s^j$, where for all $\varphi$, $\theta_0(\varphi) = 1$, $\theta(s; \varphi): \mathbb{C} \times \mathbb{R}^p$ is continuous in $s$ and $|\theta(s; \varphi)| \neq 0$, $|s| \leq 1$. More detailed conditions will be imposed below. The role of $\theta$ in (1.3), like $\alpha$ and $\beta$ in (1.2), is to permit parametric short memory autocorrelation. We allow for the simplest case FARIMA$(0, \delta_0, 0)$ by taking $\varphi_0$ to be empty. Another model covered by (1.3) is the exponential-spectrum one of [5] (which in conjunction with fractional differencing leads to a relatively neat covariance matrix formula [18]). Semiparametric models (where $u_t$ has nonparametric autocovariance structure; see, e.g., [19, 23]) afford still greater flexibility than (1.3), but also require larger samples in order for comparable precision to be achieved. In more moderate-sized samples, investment in a parametric model can prove worthwhile, even the simple FARIMA$(1, \delta_0, 0)$ employed in the Monte Carlo simulations reported in the supplementary material [14], while model choice procedures can be employed to choose $p_1$ and $p_2$ in the FARIMA$(p_1, \delta_0, p_2)$, as illustrated in the empirical examples included in the supplementary material [14].

We wish to estimate $\tau_0 = (\delta_0, \varphi_0)'$ from observations $x_t$, $t = 1, \ldots, n$. For any admissible $\tau = (\delta, \varphi)'$, define

$$ \varepsilon_t(\tau) = \Delta^\delta \theta^{-1}(L; \varphi)x_t, \quad t \geq 1, $$

noting that (1.1) implies $x_t = 0$, $t \leq 0$. For a given user-chosen optimizing set $T$, define as an estimate of $\tau_0$

$$ \hat{\tau} = \arg\min_{\tau \in T} R_n(\tau), $$

where

$$ R_n(\tau) = \frac{1}{n} \sum_{t=1}^{n} \varepsilon_t^2(\tau), $$

and $T = \mathcal{I} \times \Psi$, where $\mathcal{I} = \{\delta: \nabla_1 \leq \delta \leq \nabla_2\}$ for given $\nabla_1$, $\nabla_2$ such that $\nabla_1 < \nabla_2$, $\Psi$ is a compact subset of $\mathbb{R}^p$ and $\tau_0 \in \mathcal{T}$.

The estimate $\hat{\tau}$ is sometimes termed “conditional sum of squares” (though “truncated sum of squares” might be more suitable). It has the anticipated advantage of having the same limit distribution as the maximum likelihood estimate of
\( \tau_0 \) under Gaussianity, in which case it is asymptotically efficient (though here we do not assume Gaussianity). It was employed by [6] in estimation of nonfractional ARMA models (when \( \delta_0 \) is a given integer), by [15, 21] in stationary FARIMA models, where \( 0 < \delta_0 < 1/2 \), and by [3, 24] in nonstationary FARIMA models, allowing \( \delta_0 \geq 1/2 \).

The following section sets down detailed regularity conditions, a formal statement of asymptotic properties and the main proof details. Section 3 provides asymptotically normal estimates in a multivariate extension of (1.1), (1.3). Joint modeling of related processes is important both for reasons of parsimony and interpretation, and multivariate fractional processes are currently relatively untreated, even in the stationary case. Further possible extensions are discussed in Section 4. Useful lemmas are stated in Section 5. Due to space restrictions, the proofs of these lemmas, along with an analysis of finite-sample performance of the procedure and an empirical application, are included in the supplementary material [14].

2. Consistency and asymptotic normality.

2.1. Consistency of \( \hat{\tau} \). Our first two assumptions will suffice for consistency.

A1. (i) 
\[
|\theta(s; \varphi)| \neq |\theta(s; \varphi_0)|
\]
for all \( \varphi \neq \varphi_0, \varphi \in \Psi \), on a set \( S \subset \{s:|s|=1\} \) of positive Lebesgue measure;

(ii) for all \( \varphi, \theta(e^{i\lambda}; \varphi) \) is differentiable in \( \lambda \) with derivative in \( \text{Lip}(\zeta), \zeta > 1/2 \);

(iii) for all \( \lambda, \theta(e^{i\lambda}; \varphi) \) is continuous in \( \varphi \);

(iv) for all \( \varphi \in \Psi, |\theta(s; \varphi)| \neq 0, |s| \leq 1 \).

Condition (i) provides identification while (ii) and (iv) ensure that \( u_t \) is an invertible short-memory process (with spectrum that is bounded and bounded away from zero at all frequencies). Further, by (ii) the derivative of \( \theta(e^{i\lambda}; \varphi) \) has Fourier coefficients \( j\theta_j(\varphi) = O(j^{-\varsigma}) \) as \( j \to \infty \), for all \( \varphi \), from page 46 of [27], so that, by compactness of \( \Psi \) and continuity of \( \theta_j(\varphi) \) in \( \varphi \) for all \( j \),

\[
(2.1) \quad \sup_{\varphi \in \Psi} |\theta_j(\varphi)| = O(j^{-(1+\varsigma)}) \quad \text{as } j \to \infty.
\]

Also, writing \( \theta^{-1}(s; \varphi) = \phi(s; \varphi) = \sum_{j=0}^{\infty} \phi_j(\varphi)s^j \), we have \( \phi_0(\varphi) = 1 \) for all \( \varphi \), and (ii), (iii) and (iv) imply that

\[
(2.2) \quad \sup_{\varphi \in \Psi} |\phi_j(\varphi)| = O(j^{-(1+\varsigma)}) \quad \text{as } j \to \infty.
\]

Finally, (ii) also implies that

\[
(2.3) \quad \inf_{|s|=1} |\phi(s; \varphi)| > 0.
\]
Assumption A1 is easily satisfied by standard parameterizations of stationary and invertible ARMA processes (1.2) in which autoregressive and moving average orders are not both over-specified. More generally, A1 is similar to conditions employed in asymptotic theory for the estimate \( \hat{\tau} \) and other forms of Whittle estimate that restrict to stationarity (see, e.g., [8–10, 12, 21]) and not only is it readily verifiable because \( \theta \) is a known parametric function, but in practice \( \theta \) satisfying A1 are invariably employed by practitioners.

A2. The \( \epsilon_t \) in (1.3) are stationary and ergodic with finite fourth moment, and
\[
E(\epsilon_t | \mathcal{F}_{t-1}) = 0, \quad E(\epsilon_t^2 | \mathcal{F}_{t-1}) = \sigma_0^2
\]
almost surely, where \( \mathcal{F}_t \) is the \( \sigma \)-field of events generated by \( \epsilon_s, s \leq t \), and conditional (on \( \mathcal{F}_{t-1} \)) third and fourth moments of \( \epsilon_t \) equal the corresponding unconditional moments.

Assumption A2 avoids requiring independence or identity of distribution of \( \epsilon_t \), but rules out conditional heteroskedasticity. It has become fairly standard in the time series asymptotics literature since [11].

**THEOREM 2.1.** Let (1.1), (1.3) and A1, A2 hold. Then as \( n \to \infty \)
\[
\hat{\tau} \to p \tau_0.
\]

**PROOF.** We give the proof for the most general case where \( \delta_1 < \delta_0 - \frac{1}{2} \), but our proof trivially covers the \( \delta_1 \geq \delta_0 - \frac{1}{2} \) situation, for which some of the steps described below are superfluous. The proof begins standardly. For \( \varepsilon > 0 \), define
\[
N_{\varepsilon} = \{ \tau : \| \tau - \tau_0 \| < \varepsilon \}, \quad \bar{N}_{\varepsilon} = \{ \tau : \tau \notin N_{\varepsilon}, \tau \in \mathcal{T} \}. \quad \text{For small enough } \varepsilon, \quad (2.6)
\] where \( S_n(\tau) = R_n(\tau) - R_n(\tau_0) \). The remainder of the proof reflects the fact that \( R_n(\tau) \), and thus \( S_n(\tau) \), converges in probability to a well-behaved function when \( \delta > \delta_0 - \frac{1}{2} \), and diverges when \( \delta < \delta_0 - \frac{1}{2} \), while the need to establish uniform convergence, especially in a neighborhood of \( \delta = \delta_0 - \frac{1}{2} \), requires additional special treatment. Consequently, for arbitrarily small \( \eta > 0 \), such that \( \eta < \delta_0 - \frac{1}{2} - \delta_1 \), we define the nonintersecting sets \( \mathcal{T}_1 = \{ \delta : \delta_1 \leq \delta \leq \delta_0 - \frac{1}{2} - \eta \}, \quad \mathcal{T}_2 = \{ \delta : \delta_0 - \frac{1}{2} - \eta < \delta < \delta_0 - \frac{1}{2} \}, \quad \mathcal{T}_3 = \{ \delta : \delta_0 - \frac{1}{2} + \eta \leq \delta \leq \delta_0 - \frac{1}{2} + \eta \}, \quad \mathcal{T}_4 = \{ \delta : \delta_0 - \frac{1}{2} + \eta < \delta \leq \delta_1 \}. \) Correspondingly, define \( \mathcal{T}_i = \mathcal{T}_i \times \Psi, i = 1, \ldots, 4 \), so \( \mathcal{T} = \bigcup_{i=1}^4 \mathcal{T}_i \). Thus, from (2.6) it remains to prove
\[
\Pr(\inf_{\tau \in \bar{N}_{\varepsilon} \cap \mathcal{T}_i} S_n(\tau) \leq 0) \to 0 \quad \text{as } n \to \infty, \quad i = 1, \ldots, 4. \]
(2.7)
Each of the four proofs differs, and we describe them in reverse order.
Proof of (2.7) for $i = 4$. By a familiar argument, the result follows if for $\tau \in \mathcal{T}_4$ there is a deterministic function $U(\tau)$ (not depending on $n$), such that

$$S_n(\tau) = U(\tau) - T_n(\tau),$$

where

$$\inf_{\mathcal{N}_n \cap \mathcal{T}_4} U(\tau) > \epsilon,$$

$\epsilon$ throughout denoting a generic arbitrarily small positive constant, and

$$\sup_{\mathcal{T}_4} |T_n(\tau)| = o_p(1).$$

Since $x_t = 0$, $t \leq 0$, for $\tau \in \mathcal{T}_4$ we set [cf. (1.4)], $\zeta_t(\tau) = \Delta^{\delta - \delta_0} \phi(L; \varphi) u_t$, $U(\tau) = E\zeta_t^2(\tau) - \sigma_0^2$ and $T_n(\tau) = R_n(\tau_0) - \sigma_0^2 - \{R_n(\tau) - E\zeta_t^2(\tau)\}$. We may write

$$U(\tau) = \sigma_0^2 \left( \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{g(\lambda)}{g_0(\lambda)} d\lambda - 1 \right),$$

where

$$g(\lambda) = |1 - e^{i\lambda}|^{2(\delta - \delta_0)}|\phi(e^{i\lambda}; \varphi)|^2, \quad g_0(\lambda) = g(\lambda)|_{\tau = \tau_0}.$$  

For all $\tau$ $(2\pi)^{-1} \int_{-\pi}^{\pi} \log(g(\lambda)/g_0(\lambda)) d\lambda = 0$, so by Jensen’s inequality

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{g(\lambda)}{g_0(\lambda)} d\lambda \geq 1.$$  

Under A1(i), we have strict inequality in (2.10) for all $\tau \neq \tau_0$, so that by continuity in $\tau$ of the left-hand side of (2.10), (2.8) holds. Next, write

$$\epsilon_t(\tau) = \sum_{j=0}^{t-1} c_j(\tau) u_{t-j}, \quad \zeta_t(\tau) = \sum_{j=0}^{\infty} c_j(\tau) u_{t-j},$$

where $c_j(\tau) = \sum_{k=0}^{j} \phi_k(\varphi) a_{j-k}(\delta_0 - \delta)$. Because, given A2, the $\epsilon_t^2 - \sigma_0^2$ are stationary martingale differences,

$$R_n(\tau_0) - \sigma_0^2 = \frac{1}{n} \sum_{t=1}^{n} (\epsilon_t^2 - \sigma_0^2) \rightarrow_p 0 \quad \text{as } n \rightarrow \infty.$$  

Then defining $\gamma_k = E(u_t u_{t-k})$, and henceforth writing $c_j = c_j(\tau)$, (2.9) would hold on showing that

$$\sup_{\mathcal{T}_4} \left| \frac{1}{n} \sum_{t=1}^{n} \left( \sum_{j=0}^{t-1} c_j u_{t-j} \right)^2 - E \left( \sum_{j=0}^{t-1} c_j u_{t-j} \right)^2 \right| = o_p(1),$$

$$\sup_{\mathcal{T}_4} \left| \frac{1}{n} \sum_{t=1}^{n} \sum_{j=0}^{\infty} \sum_{k=0}^{t-1} c_j c_k \gamma_{j-k} \right| = o_p(1),$$

$$\sup_{\mathcal{T}_4} \left| \frac{1}{n} \sum_{t=1}^{n} \sum_{j=0}^{\infty} \sum_{k=0}^{t-1} c_j c_k \gamma_{j-k} \right| = o_p(1).$$
We first deal with (2.12). The term whose modulus is taken is
\[
\frac{1}{n} \sum_{j=0}^{n-1} c_j^2 \sum_{l=1}^{n-j} (u_l^2 - \gamma_0)
\]
\[+ \frac{2}{n} \sum_{j=0}^{n-2} \sum_{k=j+1}^{n-1} \sum_{l=k-j+1}^{n-j} c_j c_k \{ u_l u_{l-(k-j)} - \gamma_{j-k} \} \]
\[= (a) + (b). \tag{2.15} \]

First,
\[
E_{\mathcal{T}_4} |(a)| \leq \frac{1}{n} \sum_{j=0}^{n-1} \sup_{\mathcal{T}_4} c_j^2 E \left| \sum_{l=1}^{n-j} (u_l^2 - \gamma_0) \right|.
\]

It can be readily shown that, uniformly in \( j \), \( \text{Var}(\sum_{l=1}^{n-j} u_l^2) = O(n) \), so
\[
\sup_{\mathcal{T}_4}|(a)| = O_p \left( n^{-1/2} \sum_{j=1}^{\infty} j^{-2\eta-1} \right) = O_p(n^{-1/2})
\]
by Lemma 1. Next, by summation by parts, \( (b) \) is equal to
\[
\frac{2c_{n-1}}{n} \sum_{j=0}^{n-2} c_j \sum_{k=j+1}^{n-1} \sum_{l=k-j+1}^{n-j} \{ u_l u_{l-(k-j)} - \gamma_{j-k} \}
\]
\[- \frac{2}{n} \sum_{j=0}^{n-2} c_j \sum_{k=j+1}^{n-2} (c_{k+1} - c_k) \sum_{r=j+1}^{k} \sum_{l=r-j+1}^{n-j} \{ u_l u_{l-(r-j)} - \gamma_{j-r} \} \]
\[= (b_1) + (b_2). \]

It can be easily shown that, uniformly in \( j \),
\[
\text{Var} \left( \sum_{k=j+1}^{n-1} \sum_{l=k-j+1}^{n-j} u_l u_{l-(k-j)} \right) = O(n^2),
\]
so we have
\[
E_{\mathcal{T}_4} |(b_1)| \leq Kn^{-\eta-3/2}
\]
\[\times \sum_{j=1}^{n} j^{-\eta-1/2} \left\{ \text{Var} \left( \sum_{k=j+1}^{n-1} \sum_{l=k-j+1}^{n-j} u_l u_{l-(k-j)} \right) \right\}^{1/2}
\]
\[\leq Kn^{-2\eta+1}.\]
by Lemma 1, where $K$ throughout denotes a generic finite but arbitrarily large positive constant. Similarly,

\[
E \sup_{T_4}|(b_2)| \leq Kn^{-1} \sum_{j=1}^{n} j^{-\eta-1/2} \sum_{k=j+1}^{n} k^{\max(-\eta-3/2, -(1+\zeta))}
\]

\[
\times \left\{ \text{Var} \left( \sum_{r=j+1}^{k} \sum_{l=r-j+1}^{n-j} u_t u_l (r-j) \right) \right\}^{1/2}
\]

by Lemma 1, where $\zeta$ was introduced in A1(ii). It can be readily shown that

\[
\text{Var} \left( \sum_{r=j+1}^{k} \sum_{l=r-j+1}^{n-j} u_t u_l (r-j) \right) \leq K(k-j)(n-j).
\]

Take $\eta$ such that $\eta + 3/2 < 1 + \zeta$. Then

\[
E \sup_{T_4}|(b_2)| \leq Kn^{-1/2} \sum_{j=1}^{n} j^{-\eta-1/2} \sum_{k=j+1}^{n} k^{-\eta-3/2}(k-j)^{1/2}
\]

\[
\leq Kn^{-1/2} \sum_{j=1}^{n} j^{-\eta-1/2} \sum_{k=1}^{n} (k+j)^{-\eta-3/2} k^{1/2}.
\]

This is bounded by

\[
(2.16) \quad Kn^{-1/2} \sum_{j=1}^{n} j^{-3\eta-1/2} \sum_{k=1}^{n} k^{\eta-1},
\]

because $(k+j)^{-\eta-3/2} \leq j^{-2\eta} k^{-\eta-3/2}$. For small enough $\eta$, $(2.16)$ is bounded by $Kn^{-2\eta}$, to complete the proof of $(2.12)$. Next, the term whose modulus is taken in $(2.13)$ is

\[
(2.17) \quad \frac{1}{n} \sum_{t=1}^{n} \int_{-\pi}^{\pi} f(\lambda) \sum_{j=0}^{t-1} \sum_{k=t}^{\infty} c_j c_k e^{i(j-k)\lambda} d\lambda,
\]

where $f(\lambda)$ denotes the spectral density of $u_t$. By boundedness of $f$ (implied by assumption A1) and the Cauchy inequality, $(2.17)$ is bounded by

\[
Kn^{-1} \sum_{t=1}^{n} \left\{ \int_{-\pi}^{\pi} \left| \sum_{j=0}^{t-1} \sum_{k=t}^{\infty} c_j c_k e^{i(j-k)\lambda} \right|^2 d\lambda \right\}^{1/2}
\]

\[
\leq Kn^{-1} \sum_{t=1}^{n} \left\{ \sum_{j=0}^{t-1} \sum_{k=t}^{\infty} c_j^2 c_k^2 \right\}^{1/2},
\]
so the left-hand side of (2.13) is bounded by

$$Kn^{-1} \sum_{t=1}^{n} \left\{ \sum_{j=1}^{\infty} c_j e^{ij\lambda} \right\}^{1/2} \leq Kn^{-1} \sum_{t=1}^{n} t^{-\eta} \leq Kn^{-\eta} = o(1)$$

by Lemma 1, to establish (2.13). Finally, by a similar reasoning, the term whose modulus is taken in (2.14) is bounded by

$$Kn^{-1} \sum_{t=1}^{n} \left\{ \int_{-\pi}^{\pi} \left| \sum_{j=t}^{\infty} c_j e^{ij\lambda} \right|^2 d\lambda \right\}^{1/2} \leq Kn^{-1} \sum_{t=1}^{n} t^{-2\eta} \leq Kn^{-2\eta}$$

to conclude the proof of (2.14), and thence of (2.9). Thus, (2.7) is proved for $i = 4$.

With respect to (2.7) for $i = 1, 2, 3$, note from $\mathcal{T}_i \cap \mathcal{N}_\varepsilon \equiv \mathcal{T}_i$ for such $i$, and (2.11), that these results follow if

$$\text{Pr} \left( \inf_{\mathcal{T}_i} R_n(\tau) \leq K \right) \to 0 \quad \text{as } n \to \infty, \ i = 1, 2, 3.$$

**Proof of (2.7) for $i = 3$.** Denote, for any sequence $\zeta_t, w_\varepsilon(\lambda) = n^{-1/2} \sum_{t=1}^{n} \zeta_t \times e^{it\lambda}$, $I_\varepsilon(\lambda) = |w_\varepsilon(\lambda)|^2$, the discrete Fourier transform and periodogram, respectively, and $\lambda_j = 2\pi j/n$. For $V_n(\tau)$ satisfying Lemma 3, setting $\tau^* = (\delta, \varphi_0')$,

$$R_n(\tau) = \frac{1}{n} \sum_{j=1}^{n} I_\varepsilon(\tau)(\lambda_j) = \frac{1}{n} \sum_{j=1}^{n} |\xi(e^{ij\lambda}; \varphi)|^2 I_\varepsilon(\tau^*)(\lambda_j) + \frac{1}{n} V_n(\tau),$$

where $\xi(s; \varphi) = \theta(s; \varphi_0)/\theta(s; \varphi) = \sum_{j=0}^{\infty} \xi_j(\varphi)s^j$. Then

$$\inf_{\mathcal{T}_3} R_n(\tau) \geq \inf_{\lambda \in [-\pi, \pi]} \inf_{\varphi \in \Psi} |\xi(e^{i\lambda}; \varphi)|^2 \inf_{\delta \in \mathcal{I}_3} R_n(\tau^*) - \sup_{\mathcal{T}_3} \frac{1}{n} |V_n(\tau)|.$$

Assumption A1 implies [see (2.3)]

$$\inf_{\lambda \in [-\pi, \pi]} \inf_{\varphi \in \Psi} |\xi(e^{i\lambda}; \varphi)|^2 > \epsilon.$$

Thus,

$$\inf_{\mathcal{T}_3} R_n(\tau) \geq \epsilon \inf_{\mathcal{T}_3} \frac{1}{n} \sum_{t=1}^{n} \left( \sum_{j=0}^{t-1} a_j e^{it\lambda} \right)^2$$

$$- \sup_{\mathcal{T}_3} \frac{1}{n} |V_n(\tau)| - \sup_{\mathcal{T}_3} \frac{1}{n} |W_n(\delta)|,$$

where $a_j = a_j(\delta_0 - \delta)$, and by Lemma 2

$$W_n(\delta) = \epsilon \sum_{t=1}^{n} v_t^2(\delta) + 2\epsilon \sum_{t=1}^{n} v_t(\delta) \sum_{j=0}^{t-1} a_j e^{it\lambda}.$$
By Lemma 2 and (0.6) in the proof of Lemma 3 in the supplementary material [14] (taking $\kappa = 1/2$ there in both cases)

\begin{equation}
\sup_{I_3} \frac{1}{n} |W_n(\delta)| = O_p \left( n^{-1} + \frac{\log n}{n^{1/2}} \right) = o_p(1),
\end{equation}

and also by Lemma 3 (with $\kappa = 1/2$ there)

\begin{equation}
\sup_{I_3} \frac{1}{n} |V_n(\tau)| = O_p \left( \frac{\log^2 n}{n} \right) = o_p(1).
\end{equation}

Next, note that for $\delta \in I_3$

\begin{equation}
\frac{\partial a_j^2}{\partial \delta} = -2(\psi(j + \delta_0 - \delta) - \psi(\delta_0 - \delta))a_j^2 < 0,
\end{equation}

where we introduce the digamma function $\psi(x) = (d/dx)\log\Gamma(x)$. From (2.23) and the fact that $\psi(x)$ is strictly increasing in $x > 0$,

\begin{equation}
\inf_{I_3} n^{-1} \sum_{t=1}^{n-1} \left( \sum_{j=0}^{t-1} a_j \varepsilon_{t-j} \right)^2 \geq n^{-1} \sum_{t=1}^{n-1} \sum_{j=0}^{t-1} a_j^2 \left( \frac{1}{2} - \eta \right) \varepsilon_{t-j}^2
\end{equation}

\begin{equation}
- \sup_{I_3} \left| \frac{1}{n} \sum_{t=1}^{n-1} \sum_{j \neq k} a_j a_k \varepsilon_{t-j} \varepsilon_{t-k} \right|.
\end{equation}

By a very similar analysis to that of (b) in (2.15), the second term on the right-hand side of (2.24) is bounded by

\begin{equation}
\frac{2}{n} \sup_{I_3} \left| \sum_{j=0}^{n-2} \sum_{k=j+1}^{n-1} a_j a_k \sum_{l=k-j+1}^{n-j} \varepsilon_{l} \varepsilon_{(k-l)} \right|
\end{equation}

\begin{equation}
\leq \frac{2}{n} \sup_{I_3} \left| \sum_{j=0}^{n-2} a_j \sum_{k=j+1}^{n-1} \sum_{l=k-j+1}^{n-j} \varepsilon_{l} \varepsilon_{(k-l)} \right|
\end{equation}

\begin{equation}
+ \frac{2}{n} \sup_{I_3} \left| \sum_{j=0}^{n-2} a_j \sum_{k=j+1}^{n-2} (a_{k+1} - a_k) \sum_{r=j+1}^{k} \sum_{l=r-j+1}^{n-j} \varepsilon_{l} \varepsilon_{(k-l)} \right|
\end{equation}

which has expectation bounded by

\begin{equation}
\frac{K}{n^{1/2}} \sum_{j=1}^{n} j^{-1/2} + \frac{K}{n^{1/2}} \sum_{j=1}^{n} j^{-1/2} \sum_{k=1}^{j} (k+j)^{-3/2} k^{1/2}
\end{equation}

\begin{equation}
\leq K \left( 1 + \frac{1}{n^{1/2}} \sum_{j=1}^{n} j^{-1/2-a} \sum_{k=1}^{n} k^{-1+a} \right) \leq K
\end{equation}
for any $0 < a < 1/2$. Therefore, there exists a large enough $K$ such that

\[(2.26) \quad \Pr \left( \sup_{i=3} \left| \frac{1}{n} \sum_{t=1}^{n} \sum_{j=1}^{t-1} a_j a_k \varepsilon_{t-j} \varepsilon_{t-k} \right| > K \right) \to 0\]

as $n \to \infty$. Then, noting (2.20), (2.21), (2.22), (2.26), we deduce (2.18) for $i = 3$ if

\[(2.27) \quad \Pr \left( \frac{1}{n} \sum_{t=1}^{n} \sum_{j=0}^{t-1} a_j^2 \left( \frac{1}{2} - \eta \right) \varepsilon_{t-j}^2 \leq K \right) \to 0 \quad \text{as} \quad n \to \infty.\]

Now

\[
\frac{1}{n} \sum_{t=1}^{n} \sum_{j=0}^{t-1} a_j^2 \left( \frac{1}{2} - \eta \right) \varepsilon_{t-j}^2 = \sigma_0^2 \frac{\Gamma(2\eta)}{\Gamma^2(1/2 + \eta)} + \frac{1}{n} \sum_{t=1}^{n} \sum_{j=0}^{t-1} a_j^2 \left( \frac{1}{2} - \eta \right) \left( \varepsilon_{t-j}^2 - \sigma_0^2 \right)
\]

\[= \frac{\sigma_0^2}{n} \sum_{t=1}^{n} \sum_{j=0}^{\infty} a_j^2 \left( \frac{1}{2} - \eta \right).\]

The third term on the right is clearly $O(n^{-2\eta})$, whereas, as in the treatment of $(a)$ in (2.15), the second is $O_p(n^{-1/2})$, so that (2.27) holds as $\Gamma(2\eta) / \Gamma^2(1/2 + \eta)$ can be made arbitrarily large for small enough $\eta$. This proves (2.18), and thus (2.7), for $i = 3$.

**Proof of (2.7) for $i = 2$.** Take $\eta < 1/4$ and note that $I_2 \subset [\delta_0 - \kappa, \delta_0 - \frac{1}{2} + \eta)$ for $\kappa = \eta + \frac{1}{2}$. It follows from Lemma 2 and (0.6) in the proof of Lemma 3 (see supplementary material [14]) that

\[(2.28) \quad \sup_{I_2} \frac{1}{n} |W_n(\delta)| = O_p \left( \frac{1}{n} \sum_{t=1}^{n} t^{2\eta-1} + \frac{1}{n} \sum_{t=1}^{n} t^{\eta-1/2} t^\eta \right)
\]

\[= O_p(n^{2\eta-1/2}) = o_p(1).\]

It follows from Lemma 3 that

\[(2.29) \quad \sup_{I_2} \frac{1}{n} |V_n(\tau)| = O_p(n^{-1}) = o_p(1).\]

Denote $f_n(\delta) = n^{-1} \sum_{t=1}^{n} (\sum_{j=0}^{t-1} a_j \varepsilon_{t-j})^2$. By (2.28), (2.29), it follows that (2.18) for $i = 2$ holds if for arbitrarily large $K$

\[(2.30) \quad \Pr \left( \inf_{I_2} f_n(\delta) > K \right) \to 1\]

as $n \to \infty$. Clearly,

\[(2.31) \quad \inf_{I_2} f_n(\delta) \geq \inf_{I_2} \frac{n^{2(\delta_0 - \delta)}}{n} \inf_{I_2} \frac{1}{n^{2(\delta_0 - \delta)}} \sum_{t=1}^{n} \left( \sum_{j=0}^{t-1} a_j \varepsilon_{t-j} \right)^2.\]
Defining $b_{j,n}(d) = a_j(d)/n^{d-1}$, $b_{j,n} = b_{j,n}(\delta_0 - \delta)$, the right-hand side of (2.31) is bounded below by

\[
\inf_{\mathcal{I}_2} \frac{1}{n^2} \sum_{j=0}^{n-2} b_{j,n} \sum_{l=1}^{n-j} \varepsilon_l^2 - \sup_{\mathcal{I}_2} \frac{2}{n^2} \sum_{j=0}^{n-2} \sum_{k=j+1}^{n-1} b_{j,n} b_{k,n} \sum_{l=k-j+1}^{n-j} \varepsilon_l \varepsilon_{l-(k-j)}. 
\]

For $1 \leq j \leq n$,

\[
\inf_{\mathcal{I}_2} b_{j,n} \geq \inf_{\mathcal{I}_2} \frac{\varepsilon}{\Gamma(\delta_0 - \delta)} \inf_{\mathcal{I}_2} \left( \frac{j}{n} \right)^{\delta_0 - \delta - 1} \geq \frac{\varepsilon}{\Gamma(1/2 + \eta)} \left( \frac{j}{n} \right)^{-1/2},
\]

\[
\sup_{\mathcal{I}_2} b_{j,n} \leq \sup_{\mathcal{I}_2} \frac{K}{\Gamma(\delta_0 - \delta)} \sup_{\mathcal{I}_2} \left( \frac{j}{n} \right)^{\delta_0 - \delta - 1} \leq \frac{K}{\sqrt{\pi}} \left( \frac{j}{n} \right)^{-1/2}.
\]

Then by (2.33), using summation by parts as in the analysis of (b) in (2.15), the expectation of the second term in (2.32) is bounded by

\[
\frac{K}{n} \sum_{j=1}^{n} \left( \frac{j}{n} \right)^{-1/2} + \frac{K}{n^{1/2}} \sum_{j=1}^{n} j^{-1/2} \sum_{k=1}^{n-j} k^{1/2}(k+j)^{-3/2},
\]

which, noting (2.25), is $O(1)$. Next, the first term in (2.32) is bounded below by

\[
\frac{\sigma_0^2}{n^2} \sum_{j=0}^{n-1} (n-j) b_{j,n}^2 (1/2 + \eta) - \frac{1}{n^2} \sum_{j=0}^{n-1} b_{j,n}^2 (1/2) \sum_{l=1}^{n-j} (\varepsilon_l^2 - \sigma_0^2).
\]

Using (2.33) it can be easily shown that the second term in (2.34) is $O_p(n^{-3/2} \times \sum_{j=1}^{n} n^{-1}) = O_p(n^{-1/2} \log n)$, whereas the first term is bounded below by

\[
\frac{\varepsilon}{n} \sum_{j=1}^{n} \left\{ \left( \frac{j}{n} \right)^{2\eta-1} - \left( \frac{j}{n} \right)^{2\eta} \right\}
\]

\[
\geq \frac{\varepsilon}{2} \int_{1/n}^{1} \{ x^{2\eta-1} - x^{2\eta} \} \, dx = \frac{\varepsilon}{2} \left[ \frac{x^{2\eta}}{2\eta} - \frac{x^{2\eta+1}}{2\eta+1} \right]_{1/n}^{1}
\]

\[
= \frac{\varepsilon}{4\eta(2\eta+1)} - O_p(n^{-2\eta}).
\]

Then (2.30) holds because the right-hand side of (2.35) can be made arbitrarily large on setting $\eta$ arbitrarily close to zero. This proves (2.18), and thus (2.7), for $i = 2$.

**Proof of (2.7) for $i = 1$.** Noting that $R_n(\tau) \geq n^{-2}(\sum_{t=1}^{n} \varepsilon_t(\tau))^2$,

\[
\Pr \left( \inf_{\mathcal{I}_1} R_n(\tau) > K \right) \geq \Pr \left( n^{2\eta} \inf_{\mathcal{I}_1} \left( \frac{1}{n^{\delta_0 - \delta + 1/2}} \sum_{t=1}^{n} \varepsilon_t(\tau) \right)^2 > K \right),
\]
because $\delta_0 - \delta \geq \frac{1}{2} + \eta$. Clearly $\sum_{t=1}^{n} \epsilon_t(\tau) = \sum_{j=0}^{n-1} d_j(\tau)u_{n-j}$, where

$$d_j(\tau) = \sum_{k=0}^{j} c_k(\tau) = \sum_{k=0}^{j} \phi_k(\varphi) \sum_{l=0}^{j-k} a_l(\delta_0 - \delta) = \sum_{k=0}^{j} \phi_k(\varphi) a_{j-k}(\delta_0 - \delta + 1).$$

For arbitrarily small $\epsilon > 0$, the right-hand side of (2.36) is bounded from below by

$$\Pr\left( \inf_{\mathcal{T}_1} \left( \frac{1}{n^{\delta_0 - \delta + 1/2}} \sum_{t=1}^{n} \epsilon_t(\tau) \right)^2 > \epsilon \right)$$

for $n$ large enough, so it suffices to show (2.37) $\rightarrow 1$ as $n \rightarrow \infty$. First

$$r_n(\tau) = -\frac{1}{n^{1/2}} \sum_{j=1}^{n-1} b_{j,n}(\delta_0 - \delta + 1) \sum_{k=j+1}^{\infty} \phi_k(\varphi)u_{n-j}$$

$$- \frac{1}{n^{1/2}} \sum_{j=1}^{n-1} s_{j,n}(\tau)u_{n-j}$$

$$+ \frac{\phi(1; \varphi)}{n^{1/2}} \sum_{j=0}^{n-1} b_{j,n}(\delta_0 - \delta + 1)(u_{n-j} - \theta(1; \varphi_0)\epsilon_{n-j})$$

for

$$s_{j,n}(\tau) = \sum_{k=0}^{j-1} \left( b_{k+1,n}(\delta_0 - \delta + 1) - b_{k,n}(\delta_0 - \delta + 1) \right) \sum_{l=0}^{k} \phi_{j-l}(\varphi),$$

where (2.38) is routinely derived, noting that by summation by parts

$$d_j(\tau) = a_j(\delta_0 - \delta + 1)$$

$$\times \sum_{k=0}^{j} \phi_k(\varphi) - \sum_{k=0}^{j-1} \left( a_{k+1}(\delta_0 - \delta + 1) - a_k(\delta_0 - \delta + 1) \right) \sum_{l=0}^{k} \phi_{j-l}(\varphi).$$

Now

$$\inf_{\mathcal{T}_1} \left( \frac{1}{n^{\delta_0 - \delta + 1/2}} \sum_{t=1}^{n} \epsilon_t(\tau) \right)^2 \geq \theta^2(1; \varphi_0) \inf_{\mathcal{T}_1} \phi^2(1; \varphi) \inf_{\mathcal{T}_1} h_n^2(\delta)$$

$$- K \sup_{\mathcal{T}_1} |\theta(1; \varphi_0)| \sup_{\mathcal{T}_1} |h_n(\delta)| \sup_{\mathcal{T}_1} |r_n(\tau)|.$$
Noting (2.3) and that under A1, sup_{\psi} |\phi(1; \varphi)| < \infty, the required result follows on showing that

\begin{align}
(2.39) \quad \sup_{T_1} |r_{n}(\tau)| &= o_p(1), \\
(2.40) \quad \sup_{I_1} |h_{n}(\delta)| &= O_p(1), \\
(2.41) \quad \Pr \left( \inf_{I_1} h_{n}^2(\delta) > \epsilon \right) &\to 1
\end{align}
as \( n \to \infty \).

The proof of (2.40) is omitted as it is similar to and much easier than the proof of (2.39), which we now give. Let \( r_{n}(\tau) = \sum_{i=1}^{3} r_{in}(\tau) \). By the Cauchy inequality

\[ \sup_{T_1} |r_{1n}(\tau)| \leq \frac{1}{n^{1/2}} \left( \sum_{j=0}^{n-1} \sup_{I_1} b_{j,n}(\delta_0 - \delta + 1) \left( \sup_{\psi} \sum_{k=j+1}^{\infty} |\phi_k(\varphi)| \right)^2 \sum_{j=1}^{n} u_j^2 \right)^{1/2}, \]

so that by (2.2), noting that \( E(\sum_{j=1}^{n} u_j^2)^{1/2} \leq Kn^{1/2} \),

\[ E \sup_{T_1} |r_{1n}(\tau)| \leq K \left( \sum_{j=1}^{n} \left( \frac{j}{n} \right)^{1+2\eta} j^{-2\zeta} \right)^{1/2} \leq Kn^{1/2-\zeta} = o(1), \]
because \( \zeta > 1/2 \) by A1(ii). Next, by summation by parts

\[ r_{2n}(\tau) = -\frac{s_{n-1,n}(\tau)}{n^{1/2}} \sum_{j=1}^{n-1} u_{n-j} + \frac{1}{n^{1/2}} \sum_{j=1}^{n-2} (s_{j+1,n}(\tau) - s_{j,n}(\tau)) \sum_{k=1}^{j} u_{n-k}, \]

so

\begin{align}
(2.42) \quad \sup_{T_1} |r_{2n}(\tau)| &\leq \frac{\sup_{T_1} |s_{n-1,n}(\tau)|}{n^{1/2}} \left| \sum_{j=1}^{n-1} u_{n-j} \right| \\
&\quad + \frac{1}{n^{1/2}} \sum_{j=1}^{n-2} \sup_{T_1} |s_{j+1,n}(\tau) - s_{j,n}(\tau)| \left| \sum_{k=1}^{j} u_{n-k} \right|.
\end{align}

Given that \( a_{k+1}(\delta_0 - \delta + 1) - a_k(\delta_0 - \delta + 1) = a_{k+1}(\delta_0 - \delta) \),

\[ s_{j,n}(\tau) = \frac{1}{n^{\delta_0-\delta}} \sum_{k=0}^{j-1} a_{k+1}(\delta_0 - \delta) \sum_{l=0}^{k} \phi_{j-l}(\varphi), \]
so as $E|\sum_{j=1}^{n-1} u_j| \leq Kn^{1/2}$, noting (2.2) and Stirling’s approximation, the expectation of the first term on the right-hand side of (2.42) is bounded by

$$K \sum_{k=1}^{n} \sup_{I_1} \left( \frac{k}{n} \right)^{\delta_0 - \delta} k^{-1} \sum_{l=1}^{k} (n - l)^{-1 - \varsigma}$$

$$\leq \frac{K}{n^{1/2 + \eta}} \sum_{k=1}^{n} k^{-1/2 + \eta} (n - k)^{-1/2}$$

$$\leq \frac{K}{n^{1/2}} \frac{1}{n} \sum_{k=1}^{n} \left( \frac{k}{n} \right)^{-1/2 + \eta} \left( 1 - \frac{k}{n} \right)^{-1/2}$$

$$\leq Kn^{-1/2}.$$  

Next, noting that $a_{j+1}(\delta_0 - \delta) - a_j(\delta_0 - \delta) = a_{j+1}(\delta_0 - \delta - 1)$, it can be shown that

$$s_{j+1,n}(\tau) - s_{j,n}(\tau) = \frac{1}{n^{\delta_0 - \delta}} \sum_{k=1}^{j} \phi_k(\varphi) \sum_{l=j-k+2}^{j+1} a_l(\delta_0 - \delta - 1)$$

$$+ \frac{\phi_{j+1}(\varphi)}{n^{\delta_0 - \delta}} \sum_{l=1}^{j+1} a_l(\delta_0 - \delta).$$  

(2.43)

Thus, noting that, uniformly in $j, n$, $E|\sum_{k=1}^{j} u_{n-k}| \leq K j^{1/2}$, by previous arguments the contribution of the last term on the right-hand side of (2.43) to the expectation of the second term on the right-hand side of (2.42) is bounded by

$$\frac{K}{n^{1/2}} \sum_{j=1}^{n} j^{1/2} j^{-1 - \varsigma} \sup_{I_1} \left( \frac{j}{n} \right)^{\delta_0 - \delta} \leq \frac{K}{n^{1/2}} \sum_{j=1}^{n} j^{-1/2 - \varsigma} \left( \frac{j}{n} \right)^{1/2 + \eta}$$

$$\leq Kn^{-\varsigma}.$$  

By identical arguments, the contribution of the first term on the right-hand side of (2.43) to the expectation of the last term on the right-hand side of (2.42) is bounded by

$$\frac{K}{n^{1/2}} \sum_{j=1}^{n} j^{1/2} \sum_{k=1}^{j-1} k^{-1 - \varsigma} \sum_{l=j-k}^{j} \sup_{I_1} \left( \frac{l}{n} \right)^{\delta_0 - \delta} l^{-2}$$

$$\leq \frac{K}{n^{1+\eta}} \sum_{j=1}^{n} j^{1/2} \sum_{k=1}^{j-1} k^{-1 - \varsigma} \sum_{l=j-k}^{j} l^{-3/2 + \eta}.$$  

(2.44)
Given that \( \sum_{l=1}^{j} l^{-\frac{3}{2}+\eta} \leq K(j-k)^{-\frac{3}{2}+\eta}k \), the right-hand side of (2.44) is bounded by

\[
\frac{K}{n^{1+\eta}} \sum_{j=1}^{n} j^{1/2} \sum_{k=1}^{j-1} k^{-\frac{3}{2}+\eta} (j-k)^{-3/2+\eta} \leq \frac{K}{n^{1+\eta}} \sum_{j=1}^{n} j^{1/2} \sum_{k=1}^{[j/2]} k^{-\frac{3}{2}+\eta} (j-k)^{-3/2+\eta} + \frac{K}{n^{1+\eta}} \sum_{j=1}^{n} j^{1/2} \sum_{k=[j/2]+1}^{j-1} k^{-\frac{3}{2}+\eta} (j-k)^{-3/2+\eta},
\]

where \([\cdot]\) denotes integer part. Clearly, the right-hand side of (2.45) is bounded by

\[
\sum_{j=1}^{n} j^{1/2} \sum_{k=1}^{j-1} k^{-\frac{3}{2}+\eta} (j-k)^{-3/2+\eta} \leq K(n^{-\frac{3}{2}+\eta} + n^{1/2-\frac{3}{2}+\eta}),
\]

so \( \sup_{T_1} |r_{2n}(\tau)| = o_p(1) \) because \( \zeta > 1/2 \). Next, writing \( u_t = \theta(1; \varphi_0) \varepsilon_t + \tilde{\varepsilon}_{t-1} - \hat{\varepsilon}_t, \) for \( \tilde{\varepsilon}_t = \sum_{j=\infty}^{\infty} \hat{\theta}_j(\varphi_0) \varepsilon_{t-j}, \hat{\theta}_j(\varphi_0) = \sum_{k=j+1}^{\infty} \theta_k(\varphi_0) \), where, by A1, A2, \( \tilde{\varepsilon}_t \) is well defined in the mean square sense, we have

\[
r_{3n}(\tau) = -\frac{\phi(1; \varphi)}{n^{\delta_0-\delta+1/2}} \left( \sum_{j=0}^{n-1} a_j(\delta_0-\delta) \tilde{\varepsilon}_{n-k} - a_{n-1}(\delta_0-\delta+1) \tilde{\varepsilon}_0 \right).
\]

In view of previous arguments, it is straightforward to show that \( \sup_{T_1} |r_{3n}(\tau)| = o_p(1) \), to conclude the proof of (2.39).

Finally, we prove (2.41). Considering \( h_n(\delta) \) as a process indexed by \( \delta \), we show first that

\[
h_n(\delta) \Rightarrow \int_0^1 \frac{(1-s)^{\delta_0-\delta}}{\Gamma(\delta_0-\delta+1)} dB(s),
\]

where \( B(s) \) is a scalar Brownian motion with variance \( \sigma_0^2 \) and \( \Rightarrow \) means weak convergence in the space of continuous functions on \( I_1 \). We give this space the uniform topology. Convergence of the finite-dimensional distributions follows by Theorem 1 of [13], noting that A2 implies conditions A(i), A(ii) and A(iii) in [13] (in particular A2 implies that the fourth-order cumulant spectral density function of \( \varepsilon_t \) is bounded). Next, by Theorem 12.3 of [4], if for all fixed \( \delta \in I_1 \) \( h_n(\delta) \) is a tight sequence, and if for all \( \delta_1, \delta_2 \in I_1 \) and for \( K \) not depending on \( \delta_1, \delta_2, n \)

\[
E(h_n(\delta_1) - h_n(\delta_2))^2 \leq K(\delta_1 - \delta_2)^2,
\]

then the process \( h_n(\delta) \) is tight, and (2.46) would follow. First, for fixed \( \delta \), it is straightforward to show that \( \sup_n E(h_n^2(\delta)) < \infty \), so \( h_n(\delta) \) is uniformly integrable.
and therefore tight. Next,

\[
E(h_n(\delta_1) - h_n(\delta_2))^2
\]

\[
= \frac{\sigma_0^2}{n} \sum_{j=0}^{n-1} (b_{j,n}(\delta_0 - \delta_1 + 1) - b_{j,n}(\delta_0 - \delta_2 + 1))^2
\]

\[
= \frac{\sigma_0^2 (\delta_1 - \delta_2)^2}{n} \sum_{j=0}^{n-1} \frac{(a'_j(\delta_0 - \delta + 1) - a_j(\delta_0 - \delta + 1) \log n)^2}{n^2(\delta - \delta)}
\]

by the mean value theorem, where \(\delta = \delta_n\) is an intermediate point between \(\delta_1\) and \(\delta_2\). As in Lemma D.1 of [22],

\[
a'_j(\delta_0 - \delta + 1) - a_j(\delta_0 - \delta + 1) \log n
\]

\[
= (\psi(j + \delta_0 - \delta + 1) - \psi(\delta_0 - \delta + 1) - \log n)a_j(\delta_0 - \delta + 1).
\]

Now (2.47) holds on showing that, for \(\delta \in I_1\),

\[
\frac{\psi^2(\delta_0 - \delta + 1)}{n} \sum_{j=0}^{n-1} b_{j,n}(\delta_0 - \delta + 1) \leq K, \tag{2.48}
\]

\[
\frac{1}{n} \sum_{j=0}^{n-1} (\psi(j + \delta_0 - \delta + 1) - \log n)^2 b_{j,n}(\delta_0 - \delta + 1) \leq K. \tag{2.49}
\]

By Stirling’s approximation, the left-hand side of (2.48) is bounded by

\[
K \frac{\psi^2(\delta_0 - \nabla_1 + 1)}{n} \sum_{j=1}^{n} \sup_{I_1} \left( \frac{j}{n} \right)^{2(\delta_0 - \delta)} \leq K \frac{\psi^2(\delta_0 - \nabla_1 + 1)}{n} \sum_{j=1}^{n} \sup_{I_1} \left( \frac{j}{n} \right)^{1+2\eta} \leq K.
\]

Regarding (2.49), it can be shown that uniformly in \(I_1\), \(\psi(j + \delta_0 - \delta + 1) = \log j + O(j^{-1})\) (see, e.g., [1], page 259). Thus, apart from a remainder term of smaller order, the left-hand side of (2.49) is bounded by

\[
K \frac{1}{n} \sum_{j=1}^{n} \left( \log \frac{j}{n} \right)^2 b_{j,n}(\delta_0 - \delta + 1) \leq K \frac{1}{n} \sum_{j=1}^{n} \left( \log \frac{j}{n} \right)^2 \left( \frac{j}{n} \right)^{1+2\eta}
\]

uniformly in \(I_1\), the right-hand side of (2.50) being bounded by \(K \int_0^1 (\log x)^2 dx = 2K\), to conclude the proof of tightness. Then by the continuous mapping theorem

\[
\inf_{I_1} h_n^2(\delta) \rightarrow \inf_{I_1} \left( \int_0^1 \frac{(1-s)^{\delta_0 - \delta}}{\Gamma(\delta_0 - \delta + 1)} dB(s) \right)^2.
\]
This is a.s. positive because the quantity whose infimum is taken is a \( \chi^2_1 \) random variable times \( \sigma_0^2 / [(2(\delta_0 - \delta) + 1)\Gamma(\delta_0 - \delta + 1)^2] \), which is bounded away from zero on \( \mathcal{I}_1 \). Thus as \( n \to \infty \)

\[
\Pr \left( \inf_{\mathcal{I}_1} h_n^2(\delta) > \epsilon \right) \to \Pr \left( \inf_{\mathcal{I}_1} \left( \int_0^1 \frac{(1-s)^{\delta_0 - \delta}}{\Gamma(\delta_0 - \delta + 1)} dB(s) \right)^2 > \epsilon \right),
\]

and (2.41) follows as \( \epsilon \) is arbitrarily small. Then we conclude (2.18), and thus (2.7), for \( i = 1 \).

\[ \square \]

2.2. Asymptotic normality of \( \hat{\tau} \). This requires an additional regularity condition.

A3. (i)

\[ \tau_0 \in \text{int} \ T; \]

(ii) for all \( \lambda, \theta(e^{i\lambda}; \varphi) \) is twice continuously differentiable in \( \varphi \) on a closed neighborhood \( \mathcal{N}_\epsilon(\varphi_0) \) of radius \( 0 < \epsilon < 1/2 \) about \( \varphi_0 \):

(iii) the matrix

\[
A = \begin{pmatrix}
\frac{\pi^2}{6} & -\sum_{j=1}^{\infty} b'_j(\varphi_0)/j \\
-\sum_{j=1}^{\infty} b_j(\varphi_0)/j & -\sum_{j=1}^{\infty} b_j(\varphi_0)b'_j(\varphi_0)
\end{pmatrix}
\]

is nonsingular, where \( b_j(\varphi_0) = \sum_{k=0}^{j-1} \theta_k(\varphi_0) \partial \phi_{j-k}(\varphi_0)/\partial \varphi. \)

By compactness of \( \mathcal{N}_\epsilon(\varphi_0) \) and continuity of \( \partial \phi_j(\varphi)/\partial \varphi_i, \partial^2 \phi_j(\varphi)/\partial \varphi_i\partial \varphi_l \), for all \( j \), with \( i, l = 1, \ldots, p \), where \( \varphi_i \) is the \( i \)th element of \( \varphi \), A1(ii), A1(iv) and A3(ii) imply that, as \( j \to \infty \)

\[
\sup_{\varphi \in \mathcal{N}_\epsilon(\varphi_0)} \left| \frac{\partial \phi_j(\varphi)}{\partial \varphi_i} \right| = O(j^{-(1+\varsigma)}), \quad \sup_{\varphi \in \mathcal{N}_\epsilon(\varphi_0)} \left| \frac{\partial^2 \phi_j(\varphi)}{\partial \varphi_i \partial \varphi_l} \right| = O(j^{-(1+\varsigma)}),
\]

which again is satisfied in the ARMA case. As with A1, A3 is similar to conditions employed under stationarity, and can readily be checked in general.

**Theorem 2.2.** Let (1.1), (1.3) and A1–A3 hold. Then as \( n \to \infty \)

\[ n^{1/2}(\hat{\tau} - \tau_0) \to_d N(0, A^{-1}). \]

**Proof.** The proof standardly involves use of the mean value theorem, approximation of a score function by a martingale so as to apply a martingale convergence theorem, and convergence in probability of a Hessian in a neighborhood
of $\tau_0$. From the mean value theorem, (2.51) follows if we prove that

$$\frac{\sqrt{n}}{2} \frac{\partial R_n(\tau_0)}{\partial \tau} \to_d N(0, \sigma_0^4 A), \quad (2.52)$$

$$\frac{1}{2} \frac{\partial^2 R_n(\overline{\tau})}{\partial \tau \partial \tau'} \to_p \sigma_0^2 A, \quad (2.53)$$

where $||\overline{\tau} - \tau_0|| \leq ||\hat{\tau} - \tau_0||$.

**Proof of (2.52).** It suffices to prove

$$\frac{1}{\sqrt{n}} \sum_{t=2}^{n} \varepsilon_t \sum_{j=1}^{\infty} m_j(\phi_0) \varepsilon_{t-j} = o_p(1) \quad (2.54)$$

and

$$\frac{1}{\sqrt{n}} \sum_{t=2}^{n} \varepsilon_t \sum_{j=1}^{\infty} m_j(\phi_0) \varepsilon_{t-j} \to_d N(0, \sigma_0^4 A), \quad (2.55)$$

where $m_j(\phi_0) = (-j^{-1}, b'_j(\phi_0))'$. By Lemma 2, the left-hand side of (2.54) is the $(p + 1) \times 1$ vector $(r_1 + r_2 + r_3, (s_1 + s_2)')'$, where

$$r_1 = \frac{1}{\sqrt{n}} \sum_{t=2}^{n} \varepsilon_t \sum_{j=t}^{\infty} \varepsilon_{t-j},$$

$$r_2 = \frac{1}{\sqrt{n}} \sum_{t=2}^{n} \varepsilon_t \sum_{j=1}^{t-1} \sum_{k=t-j}^{\infty} \phi_k(\phi_0) u_{t-j-k},$$

$$r_3 = -\frac{1}{\sqrt{n}} \sum_{t=2}^{n} v_t(\delta_0) \sum_{j=1}^{t-1} \sum_{k=0}^{t-j-1} \phi_k(\phi_0) u_{t-j-k},$$

$$s_1 = \frac{1}{\sqrt{n}} \sum_{t=2}^{n} \varepsilon_t \sum_{j=t}^{\infty} \frac{\partial \phi_j(\phi_0)}{\partial \varphi} u_{t-j},$$

$$s_2 = \frac{1}{\sqrt{n}} \sum_{t=2}^{n} v_t(\delta_0) \sum_{j=1}^{t-1} \frac{\partial \phi_j(\phi_0)}{\partial \varphi} u_{t-j}.$$

Clearly, $E(r_1) = 0$, and

$$\text{Var}(r_1) = \frac{1}{n} \sum_{t=2}^{n} \sum_{j=1}^{\infty} \sum_{s=2}^{\infty} \sum_{k=s}^{\infty} \sum_{l=1}^{\infty} E(\varepsilon_t \varepsilon_s \varepsilon_{t-j-k} \varepsilon_{s-l}) \leq \frac{\sigma_0^4}{n} \sum_{t=2}^{n} \sum_{j=t}^{\infty} \frac{1}{j^2} = O\left(\frac{\log n}{n}\right),$$

noting that, by A2, the $\varepsilon_t$ and $\varepsilon_t^2 - \sigma_0^2$ are martingale difference sequences. Thus, $r_1 = O_p(n^{-1/2} \log^{1/2} n)$. Next, $E(r_2) = 0$, and $\text{Var}(r_2)$ equals

$$\frac{1}{n} \sum_{t=2}^{n} \sum_{j=1}^{t-1} \sum_{k=t-j}^{\infty} \sum_{s=2}^{t-1} \sum_{l=1}^{\infty} \sum_{m=s}^{\infty} \phi_k(\phi_0) \phi_m(\phi_0) \frac{1}{j^l} E(\varepsilon_t \varepsilon_s u_{t-j-k} u_{s-l-m}). \quad (2.56)$$
From (1.3) and A2, the expectation is $\sigma_0^2 \gamma_{j+k-t-m}$ for $s = t$, and zero otherwise. By A1, $u_t$ has bounded spectral density. Thus, (2.56) is bounded by

$$
K \frac{1}{n} \sum_{t=2}^{n} \int_{-\pi}^{\pi} \sum_{j=1}^{t-1} \sum_{k=t-j}^{\infty} \frac{\phi_k(\varphi_0)}{j} e^{i(j+k)\mu} \left| e^{ij\lambda} \right|^2 d\mu
$$

$$
\leq \frac{K}{n} \sum_{t=2}^{n} \sum_{j=1}^{t-1} \sum_{k=t-j}^{\infty} \frac{\phi_k(\varphi_0)\phi_{j+k-l}(\varphi_0)}{jl}
$$

$$
\leq \frac{K}{n} \sum_{t=2}^{n} \sum_{j=1}^{t-1} \sum_{k=t-j}^{\infty} \frac{k^{-1-\varsigma} (j+k-l)^{-1-\varsigma}}{jl}
$$

$$
\leq \frac{K}{n} \sum_{t=2}^{n} \sum_{l=1}^{t-1} \frac{(t-l)^{-1-\varsigma}}{l} \sum_{j=1}^{t-1} \frac{(t-j)^{-\varsigma}}{j}.
$$

Now

$$
\sum_{l=1}^{t-1} \frac{(t-l)^{-1-\varsigma}}{l} = \sum_{l=1}^{[t/2]} \frac{(t-l)^{-1-\varsigma}}{l} + \sum_{l=[t/2]+1}^{t-1} \frac{(t-l)^{-1-\varsigma}}{l}
$$

$$
\leq K (t^{-1-\varsigma} \log t + t^{-1}) \leq \frac{K}{t}.
$$

Then $\text{Var}(r_2) = O(n^{-1} \sum_{t=2}^{n} t^{-1} \sum_{j=1}^{t-1} j^{-1}) = O(n^{-1} \log^2 n)$, so

$$
r_2 = O_p(n^{-1/2} \log n).
$$

Next, by Lemma 2

$$
r_3 = O_p \left( n^{-1/2} \sum_{t=2}^{n} t^{-1/2-\varsigma} \log t \right) = O_p(n^{-1/2}).
$$

Also, $E(s_1) = 0$ and

$$
\text{Var}(s_1) = O(1) \left( \frac{1}{n} \sum_{t=2}^{n} \sum_{j=t}^{\infty} \sum_{k=t-j}^{\infty} \frac{\partial \phi_j(\varphi_0)}{\partial \varphi} \frac{\partial \phi_k(\varphi_0)}{\partial \varphi'} E(u_{t-j}u_{t-k}) \right)
$$

$$
= O \left( \frac{1}{n} \int_{-\pi}^{\pi} \left| \sum_{j=t}^{\infty} \frac{\partial \phi_j(\varphi_0)}{\partial \varphi} e^{ij\lambda} \right|^2 d\lambda \right)
$$

$$
= O \left( \frac{1}{n} \sum_{t=2}^{n} \sum_{j=t}^{\infty} \left| \frac{\partial \phi_j(\varphi_0)}{\partial \varphi} \right|^2 \right) = O \left( \frac{1}{n} \sum_{t=2}^{n} t^{-1-2\varsigma} \right) = O(n^{-1}).
$$
since \( \varsigma > \frac{1}{2} \), \( \| \cdot \| \) denoting Euclidean norm. Finally, by Lemmas 2 and 4

\[
s_2 = O_p \left( n^{-1/2} \sum_{i=1}^{n} t^{-1/2-\varsigma} \right) = O_p(n^{-1/2}),
\]
to conclude the proof of (2.54).

Next, (2.55) holds by the Cramér–Wold device and, for example, Theorem 1 of [7] on showing that

\[
(2.57) \quad E \left( \varepsilon_t \sum_{j=1}^{\infty} m_j(\varphi_0)\varepsilon_{t-j} \big| \mathcal{F}_{t-1} \right) = 0 \quad \text{a.s.}
\]

and

\[
\frac{1}{n} \sum_{t=2}^{n} E \left( \varepsilon_t^2 \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} m_j(\varphi_0)m_k'(\varphi_0)\varepsilon_{t-j}\varepsilon_{t-k} \big| \mathcal{F}_{t-1} \right)
\]

\[
\frac{1}{n} \sum_{t=2}^{n} E \left( \varepsilon_t^2 \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} m_j(\varphi_0)m_k'(\varphi_0)\varepsilon_{t-j}\varepsilon_{t-k} \big| \mathcal{F}_{t-1} \right) \to_p 0,
\]

because \( E(\varepsilon_t^2 \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} m_j(\varphi_0)m_k'(\varphi_0)\varepsilon_{t-j}\varepsilon_{t-k} \big| \mathcal{F}_{t-1} \) has expectation \( \sigma_0^2 A \), noting that the Lindeberg condition is satisfied as \( \varepsilon_t \sum_{j=1}^{\infty} m_j(\varphi_0)\varepsilon_{t-j} \) is stationary with finite variance. Now (2.57) follows as \( \varepsilon_{t-j}, j \geq 1 \), is \( \mathcal{F}_{t-1} \)-measurable, whereas the left-hand side of (2.58) is

\[
\frac{\sigma_0^2}{n} \sum_{t=2}^{n} \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} m_j(\varphi_0)m_k'(\varphi_0)(\varepsilon_{t-j}\varepsilon_{t-k} - E(\varepsilon_{t-j}\varepsilon_{t-k})) \to_p 0,
\]

because \( \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} m_j(\varphi_0)m_k'(\varphi_0)(\varepsilon_{t-j}\varepsilon_{t-k} - E(\varepsilon_{t-j}\varepsilon_{t-k})) \) is stationary ergodic with mean zero. This completes the proof of (2.55), and thus (2.52).

Proof of (2.53). Denote by \( N_\varepsilon \) an open neighborhood of radius \( \varepsilon < 1/2 \) about \( \tau_0 \), and

\[
(2.59) \quad A_n(\tau) = \frac{1}{n} \sum_{t=2}^{n} \sum_{j=0}^{t-1} \sum_{k=0}^{t-1} \left( c_j \frac{\partial^2 c_k}{\partial \tau \partial \tau'} + \frac{\partial c_j}{\partial \tau} \frac{\partial c_k}{\partial \tau'} \right) \gamma_{k-j},
\]

\[
(2.60) \quad A(\tau) = \sum_{j=0}^{\infty} \sum_{k=1}^{\infty} \left( c_j \frac{\partial^2 c_k}{\partial \tau \partial \tau'} + \frac{\partial c_j}{\partial \tau} \frac{\partial c_k}{\partial \tau'} \right) \gamma_{k-j}.
\]

Trivially,

\[
1 \frac{\partial^2 R_n(\tau)}{\partial \tau \partial \tau'} = \frac{1}{2} \frac{\partial^2 R_n(\tau)}{\partial \tau \partial \tau'} - A_n(\tau) + A_n(\tau) - A(\tau) + A(\tau) - A(\tau_0) + A(\tau_0).
\]

Because \( c_j(\tau_0) = \phi_j(\tau_0) \), it follows that \( \sum_{j=0}^{\infty} c_j(\tau_0)u_{t-j} = \varepsilon_t \), so the first term in \( A(\tau_0) \) is identically zero. Also, as in the proof of (2.55), the second term of
\( A(\tau_0) \) is identically \( \sigma_0^2 A \). Thus, given that by Slutzky’s theorem and continuity of \( A(\tau) \) at \( \tau_0 \), \( A(\tau) - A(\tau_0) = o_p(1) \), (2.53) holds on showing

\[
\sup_{\tau \in \mathcal{N}_\epsilon} \left\| \frac{1}{2} \frac{\partial^2 R_n(\tau)}{\partial \tau \partial \tau'} - A_n(\tau) \right\| = o_p(1),
\]

(2.61)

\[
\sup_{\tau \in \mathcal{N}_\epsilon} \| A_n(\tau) - A(\tau) \| = o_p(1)
\]

for some \( \epsilon > 0 \), as \( n \to \infty \). As \( \epsilon < 1/2 \), the proof for (2.61) is almost identical to that for (2.12), noting the orders in Lemma 4. To prove (2.62), we show that

\[
\sup_{\tau \in \mathcal{N}_\epsilon} \left\| \frac{1}{n} \sum_{t=2}^{t-1} \sum_{j=0}^{t-1} c_j \frac{\partial^2 c_k}{\partial \tau \partial \tau'} \gamma_{k-j} - \sum_{j=0}^{\infty} \sum_{k=1}^{\infty} c_j \frac{\partial^2 c_k}{\partial \tau \partial \tau'} \gamma_{k-j} \right\| = o_p(1),
\]

(2.63)

is \( o_p(1) \), the proof for the corresponding result concerning the difference between the second terms in (2.59), (2.60) being almost identical. By Lemma 4, (2.63) is bounded by

\[
\frac{K}{n} \sum_{t=1}^{n} \sum_{j=1}^{t} \sum_{k=t+1}^{\infty} j^{\epsilon-1} k^{\epsilon-1} (k - j)^{-1-\varsigma} \log^2 k + \frac{K}{n} \sum_{t=1}^{\infty} \sum_{j=t}^{\infty} j^{2\epsilon-2} \log^2 j
\]

(2.64)

\[
+ \frac{K}{n} \sum_{t=1}^{n} \sum_{j=t}^{\infty} \sum_{k=j+1}^{\infty} j^{\epsilon-1} k^{\epsilon-1} (k - j)^{-1-\varsigma} \log^2 k,
\]

noting that (2.1) implies that \( \gamma_j = O(j^{-1-\varsigma}) \). The first term in (2.64) is bounded by

\[
\frac{K}{n} \sum_{t=1}^{n} t^\epsilon \sum_{k=t+1}^{\infty} k^{\epsilon+a-1} (k - t)^{-1-\varsigma} \leq \frac{K}{n} \sum_{t=1}^{\infty} t^\epsilon \sum_{k=1}^{\infty} (k + t)^{\epsilon+a-1} k^{-1-\varsigma}
\]

(2.65)

for any \( a > 0 \). Choosing \( a \) such that \( 2\epsilon + a < 1 \), (2.65) is bounded by

\[
\frac{K}{n} \sum_{t=1}^{n} t^{2\epsilon+a-1} \sum_{k=1}^{\infty} k^{-1-\varsigma} = O(n^{2\epsilon+a-1}) = o(1).
\]

Similarly, the second term in (2.64) can be easily shown to be \( o(1) \), whereas the third term is bounded by

\[
\frac{K}{n} \sum_{t=1}^{n} \sum_{j=t}^{\infty} j^{2\epsilon+a-2} \sum_{k=j+1}^{\infty} (k - j)^{-1-\varsigma}
\]

(2.66)

for any \( a > 0 \), so choosing again \( a \) such that \( 2\epsilon + a < 1 \), (2.66) is \( O(n^{2\epsilon+a-1}) = o(1) \), to conclude the proof of (2.53), and thus of the theorem. \( \square \)
3. Multivariate extension. When observations on several related time series are available joint modeling can achieve efficiency gains. We consider a vector $x_t = (x_{1t}, \ldots, x_{rt})'$ given by

$$x_t = \Lambda_0^{-1}\{u_t \mathbb{1} (t > 0)\}, \quad t = 0, \pm 1, \ldots,$$

where $u_t = (u_{1t}, \ldots, u_{rt})'$,

$$u_t = \Theta(L; \varphi_0)e_t, \quad t = 0, \pm 1, \ldots,$$

in which $e_t = (e_{1t}, \ldots, e_{rt})'$, $\varphi_0$ is (as in the univariate case) a $p \times 1$ vector of short-memory parameters, $\Theta(s; \varphi) = \sum_{j=0}^{\infty} \Theta_j(\varphi)s^j$, $\Theta_0(\varphi) = I_r$ for all $\varphi$, and $\Lambda_0 = \text{diag}(\Lambda_0^{\delta_{01}}, \ldots, \Lambda_0^{\delta_{0r}})$, where the memory parameters $\delta_{0i}$ are unknown real numbers. In general, they can all be distinct but for the sake of parsimony we allow for the possibility that they are known to lie in a set of dimension $q < r$.

For example, perhaps as a consequence of pre-testing, we might believe some or all the $\delta_{0i}$ are equal, and imposing this restriction in the estimation could further improve efficiency. We introduce known functions $\delta_i = \delta_i(\delta)$, $i = 1, \ldots, r$, of $q \times 1$ vector $\delta$, such that for some $\delta_0$ we have $\delta_{0i} = \delta_i(\delta_0)$, $i = 1, \ldots, r$. We denote $\tau = (\delta', \varphi')'$ and define [cf. (1.4)]

$$e_t(\tau) = \Theta^{-1}(L; \varphi)\Lambda(\delta)x_t, \quad t \geq 1,$$

where $\Lambda(\delta) = \text{diag}(\Lambda_{\delta_1}, \ldots, \Lambda_{\delta_r})$. Gaussian likelihood considerations suggest the multivariate analogue to (1.6)

$$\mathcal{R}_n^* (\tau) = \det\{\Sigma_n(\tau)\},$$

where $\Sigma_n(\tau) = n^{-1} \sum_{t=1}^{n} e_t(\tau)e_t'(\tau)$, assuming that no prior restrictions link $\tau_0$ with the covariance matrix of $e_t$. Unfortunately our consistency proof for the univariate case does not straightforwardly extend to an estimate minimizing (3.3) if $q > 1$. Also (3.3) is liable to pose a more severe computational challenge than (1.6) since $p$ is liable to be larger in the multivariate case and $q$ may exceed 1; it may be difficult to locate an approximate minimum of (3.3) as a preliminary to iteration. We avoid both these problems by taking a single Newton step from an initial $\sqrt{n}$-consistent estimate $\tilde{\tau}$. Defining

$$H_n(\tau) = \frac{1}{n} \sum_{t=1}^{n} \left( \frac{\partial e_t(\tau)}{\partial \tau'} \right)' \Sigma_n^{-1}(\tau) \frac{\partial e_t(\tau)}{\partial \tau'},$$

$$h_n(\tau) = \frac{1}{n} \sum_{t=1}^{n} \left( \frac{\partial e_t(\tau)}{\partial \tau'} \right)' \Sigma_n^{-1}(\tau)e_t(\tau),$$

we consider the estimate

$$\hat{\tau} = \tilde{\tau} - H_n^{-1}(\tilde{\tau})h_n(\tilde{\tau}).$$

We collect together all the requirements for asymptotic normality of $\hat{\tau}$ in:
A4. (i) For all \( \varphi, \Theta(e^{i\lambda}; \varphi) \) is differentiable in \( \lambda \) with derivative in \( \text{Lip}(\varsigma), \varsigma > 1/2 \);
(ii) for all \( \varphi \), \( \det(\Theta(s; \varphi)) \neq 0, |s| \leq 1 \);
(iii) the \( \epsilon_i \) in (3.2) are stationary and ergodic with finite fourth moment, \( E(\epsilon_i|\mathcal{F}_{t-1}) = 0, E(\epsilon_i\epsilon_i'|\mathcal{F}_{t-1}) = \Sigma_0 \) almost surely, where \( \Sigma_0 \) is positive definite, \( \mathcal{F}_i \) is the \( \sigma \)-field of events generated by \( \epsilon_s, s \leq t \), and conditional (on \( \mathcal{F}_{t-1} \)) third and fourth moments and cross-moments of elements of \( \epsilon_i \) equal the corresponding unconditional moments;
(iv) for all \( \lambda, \Theta(e^{i\lambda}; \varphi) \) is twice continuously differentiable in \( \varphi \) on a closed neighborhood \( \mathcal{N}_\epsilon(\varphi_0) \) of radius \( 0 < \epsilon < 1/2 \) about \( \varphi_0 \);
(v) the matrix \( B \) having \((i, j)\)th element

\[
\sum_{k=1}^{\infty} \text{tr} \{ (d_k^{(i)}(\varphi_0))^\prime \Sigma_0^{-1} d_k^{(j)}(\varphi_0) \Sigma_0 \}
\]

is nonsingular, where

\[
d_k^{(i)}(\varphi_0) = -\frac{\partial \delta_i(\delta_0)}{\partial \delta_i} \sum_{l=1}^{k} \frac{k-l}{l} \sum_{m=0}^{k-l} \Phi_m^{(i)}(\varphi_0) \Theta_{k-l-m}(\varphi_0), \quad 1 \leq i \leq r,
\]

\[
= \sum_{l=1}^{k} \frac{\partial \Phi_l(\varphi_0)}{\partial \varphi_l} \Theta_{k-l}(\varphi_0), \quad r+1 \leq i \leq r+p,
\]

the \( \Phi_j(\varphi) \) being coefficients in the expansion \( \Theta^{-1}(s; \varphi) = \Phi(s, \varphi) = \sum_{j=0}^{\infty} \Phi_j(\varphi) s^j \), where \( \Phi_m^{(i)}(\varphi_0) \) is an \( r \times r \) matrix whose \( i \)th column is the \( i \)th column of \( \Phi_i(\varphi_0) \) and whose other elements are all zero;
(vi) \( \delta_i(\delta) \) is twice continuously differentiable in \( \delta \), for \( i = 1, \ldots, r \);
(vii) \( \tilde{\tau} \) is a \( \sqrt{n} \)-consistent estimate of \( \tau_0 \).

The components of A4 are mostly natural extensions of ones in A1, A2 and A3, are equally checkable, and require no additional discussion. The important exception is (vii). When \( \Theta(s; \varphi) \) is a diagonal matrix [as in the simplest case \( \Theta(s; \varphi) \equiv \mathbf{I}_r \), when \( x_{it} \) is a FARIMA\((0, \delta_0i; 0) \) for \( i = 1, \ldots, r \)] then \( \tilde{\tau} \) can be obtained by first carrying out \( r \) univariate fits following the approach of Section 2, and then if necessary reducing the dimensionality in a common-sense way: for example, if some of the \( \delta_0i \) are a priori equal then the common memory parameter might be estimated by the arithmetic mean of estimates from the relevant univariate fits. Notice that in the diagonal-\( \Theta \) case with no cross-equation parameter restrictions the efficiency improvement afforded by \( \tilde{\tau} \) is due solely to cross-correlation in \( \epsilon_i \), that is, non-diagonality of \( \Sigma_0 \).

When \( \Theta(s; \varphi) \) is not diagonal, it is less clear how to use the \( \sqrt{n} \)-consistent outcome of Theorem 2.2 to form \( \tilde{\tau} \). We can infer that \( u_{it} \) has spectral density matrix \((2\pi)^{-1} \Theta(e^{i\lambda}; \varphi_0) \Sigma_0 \Theta(e^{-i\lambda}; \varphi_0)^\prime \). From the \( i \)th diagonal element of this (the power spectrum of \( u_{it} \)), we can deduce a form for the Wold representation of \( u_{it} \),
corresponding to (1.3). However, starting from innovations \( \varepsilon_t \) in (3.2) satisfying (iii) of A4, it does not follow in general that the innovations in the Wold representation of \( u_{it} \) will satisfy a condition analogous to (2.4) of A2, indeed it does not help if we simply strengthen A4 such that the \( \varepsilon_t \) are independent and identically distributed. However, (2.4) certainly holds if \( \varepsilon_t \) is Gaussian, which motivates our estimation approach from an efficiency perspective. Notice that if \( u_t \) is a vector ARMA process with nondiagonal \( \Theta_1 \), in general all \( r \) univariate AR operators are identical, and of possibly high degree; the formation of \( \tilde{\tau} \) is liable to be affected by a lack of parsimony, or some ambiguity.

An alternative approach could involve first estimating the \( \delta_{0i} \) by some semiparametric approach, using these estimates to form differenced \( x_t \) and then estimating \( \phi_0 \) from these proxies for \( u_t \). This initial estimate will be less-than-\( \sqrt{n} \)-consistent, but its rate can be calculated given a rate for the bandwidth used in the semiparametric estimation. One can then calculate the (finite) number of iterations of form (3.4) needed to produce an estimate satisfying (2.51), following Theorem 5 and the discussion on page 539 of [17].

**Theorem 3.1.** Let (3.1), (3.2) and A4 hold. Then as \( n \to \infty \)

\[
(3.5) \quad n^{1/2}(\hat{\tau} - \tau_0) \to_d N(0, B^{-1}).
\]

**Proof.** Because \( \hat{\tau} \) is explicitly defined in (3.4), we start, standardly, by approximating \( h_n(\hat{\tau}) \) by the mean value theorem. Then in view of A4(vii), (3.5) follows on showing

\[
(3.6) \quad \sqrt{n}h_n(\tau_0) \to_d N(0, B),
\]

\[
(3.7) \quad H_n(\tau_0) \to_p B,
\]

\[
(3.8) \quad H_n(\tilde{\tau}) - H_n(\tau_0) \to_p 0
\]

for \( \|\tilde{\tau} - \tau_0\| \leq \|\hat{\tau} - \tau_0\| \). We only show (3.6), as (3.7), (3.8) follow from similar arguments to those given in the proof of (2.53). Noting that \( \partial \varepsilon_1(\tau_0)/\partial \tau' = 0 \), whereas for \( t \geq 2 \), \( \partial \varepsilon_t(\tau_0)/\partial \tau' \) equals

\[
\sum_{j=1}^{t-1} \left( -\Phi_j^{(1)}(\varphi_0) \sum_{k=1}^{t-j-1} \frac{u_{t-j-k}}{k}, \ldots, -\Phi_j^{(r)}(\varphi_0) \sum_{k=1}^{t-j-1} \frac{u_{t-j-k}}{k}, \right)
\]

by similar arguments to those in the proof of Theorem 2.2, it can be shown that the left-hand side of (3.6) equals

\[
\frac{1}{\sqrt{n}} \sum_{t=2}^{n} \left( \sum_{j=1}^{\infty} d_j^{(1)}(\varphi_0)\varepsilon_{t-j} \cdots \sum_{j=1}^{\infty} d_j^{(r+p)}(\varphi_0)\varepsilon_{t-j} \right)' \Sigma_0^{-1} \varepsilon_t + o_p(1).
\]
Then by the Cramér–Wold device, (3.6) holds if for any \((r + p)\)-dimensional vector \(\vartheta\) (with \(i\)th component \(\vartheta_i\))

\[
(3.9) \quad \frac{1}{\sqrt{n}} \sum_{t=2}^{n} \sum_{j=1}^{\infty} \epsilon'_{t-j} M_j'(\varphi_0) \Sigma_0^{-1} \epsilon_t \to_d N(0, \vartheta' B \vartheta),
\]

where \(M_j(\varphi_0) = \sum_{k=1}^{r+p} \vartheta_k d_j^{(k)}(\varphi_0)\). As in the proof of (2.55), (3.9) holds by Theorem 1 of [7], for example, noting that

\[
E \left( \sum_{j=1}^{\infty} \epsilon'_{t-j} M_j'(\varphi_0) \Sigma_0^{-1} \epsilon_t \right)^2 = E \left( \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} \epsilon'_{t-j} M_j'(\varphi_0) \Sigma_0^{-1} E(\epsilon_t \epsilon'_t \mid \mathcal{F}_{t-1}) \Sigma_0^{-1} M_k(\varphi_0) \epsilon_{t-k} \right)
\]

\[
= E \left( \sum_{j=1}^{\infty} \sum_{k=1}^{\infty} \text{tr}(\epsilon'_{t-j} M_j'(\varphi_0) \Sigma_0^{-1} M_k(\varphi_0) \epsilon_{t-k}) \right)
\]

\[
= \sum_{j=1}^{\infty} \text{tr}[M_j'(\varphi_0) \Sigma_0^{-1} M_j'(\varphi_0) \Sigma_0] = \vartheta' B \vartheta
\]

to conclude the proof. □

4. Further comments and extensions. (1) Our univariate and multivariate structures cover a wide range of parametric models for stationary and nonstationary time series, with memory parameters allowed to lie in a set that can be arbitrarily large. Unit root series are a special case, but unlike in the bulk of the large unit root literature, we do not have to assume knowledge that memory parameters are 1. Indeed, in Monte Carlo [14] our method out-performs one which correctly assumes the unit interval in which \(\delta_0\) lies, while in empirical examples our findings conflict with previous, unit root, ones.

(2) As the nondiagonal structure of \(A\) and \(B\) suggests, there is efficiency loss in estimating \(\varphi_0\) if memory parameters are unknown, but on the other hand if these are misspecified, \(\varphi_0\) will in general be inconsistently estimated. Our limit distribution theory can be used to test hypotheses on the memory and other parameters, after straightforwardly forming consistent estimates of \(A\) or \(B\).

(3) Our multivariate system (3.1), (3.2) does not cover fractionally cointegrated systems because \(\Sigma_0\) is required to be positive definite. On the other hand, our theory for univariate estimation should cover estimation of individual memory parameters, so long as Assumption A2, in particular, can be reconciled with the full system specification. Moreover, again on an individual basis, it should be possible to derive analogous properties of estimates of memory parameters of cointegrating
errors based on residuals that use simple estimates of cointegrating vectors, such as least squares.

(4) In a more standard regression setting, for example, with deterministic regressors such as polynomial functions of time, it should be possible to extend our theory for univariate and multivariate models to residual-based estimates of memory parameters of errors.

(5) Adaptive estimates, which have greater efficiency at distributions of unknown, non-Gaussian form, can be obtained by taking one Newton step from our estimates (as in [20]).

(6) Our methods of proof should be extendable to cover seasonally and cyclically fractionally differenced processes.

(7) Nonstationary fractional series can be defined in many ways. Our definition [(1.1) and (3.1)] is a leading one in the literature, and has been termed “Type II.” Another popular one (“Type I”) was used by [25] for an alternate type of estimate. That estimate assumes invertibility and is generally less efficient than \( \hat{\tau} \) due to the tapering required to handle nonstationarity. It seems likely that the asymptotic theory derived in this paper for \( \hat{\tau} \) can also be established in a “Type I” setting.

5. Technical lemmas. The proofs of the following lemmas appear in [14].

**Lemma 1.** Under A1

\[
\varepsilon_t(\tau) = \sum_{j=0}^{r-1} c_j(\tau)u_{t-j}
\]

with \( c_0(\tau) = 1 \) where for any \( \delta \in I \), as \( j \to \infty \),

\[
\sup_{\varphi \in \Psi} |c_j(\tau)| = O(j^{\max(\delta_0-\delta-1,-1-\varsigma)}),
\]

\[
\sup_{\varphi \in \Psi} |c_{j+1}(\tau) - c_j(\tau)| = O(j^{\max(\delta_0-\delta-2,-1-\varsigma)}).
\]

**Lemma 2.** Under A1, A2

\[
\varepsilon_t(\tau^*) = \sum_{j=0}^{r-1} a_j \varepsilon_{t-j} + v_t(\delta),
\]

where \( \tau^* = (\delta, \varphi_0) \) and for any \( \kappa \geq 1/2 \)

\[
\sup_{\delta_0-\kappa \leq \delta < \delta_0-1/2+\eta} |v_t(\delta)| = O_p(t^{\kappa-1})
\]

and \( v_t(\delta_0) = O_p(t^{-1/2-\varsigma}) \).
Lemma 3. Under A1, A2

\[
\sum_{j=1}^{n} I_{\varepsilon}(\tau, \lambda_j) = \sum_{j=1}^{n} \left( \frac{\theta(e^{i\lambda_j}; \varphi_0)}{\theta(e^{i\lambda_j}; \varphi)} \right)^2 I_{\varepsilon}(\tau, \lambda_j) + V_n(\tau),
\]

where for any real number \( \kappa \geq 1/2 \)

\[
\sup_{\delta_0 - \kappa \leq \delta < \delta_0 - 1/2 + \eta} \left| V_n(\tau) \right| = O_p\left( \log^2 n \Pi(\kappa = 1/2) + n^{2\kappa-1} \Pi(\kappa > 1/2) \right).
\]

Lemma 4. Under A3, given an open neighborhood \( N_\epsilon \) of radius \( \epsilon < 1/2 \) about \( \tau_0 \), as \( j \to \infty \),

\[
\sup_{\tau \in N_\epsilon} |c_j(\tau)| = O(j^{\epsilon-1}),
\]

\[
\sup_{\tau \in N_\epsilon} \left| \frac{\partial c_j(\tau)}{\partial \delta} \right| = O(j^{\epsilon-1} \log j),
\]

\[
\sup_{\tau \in N_\epsilon} |c_{j+1}(\tau) - c_j(\tau)| = O(j^{\max(\epsilon-2, -1, -\varsigma)}),
\]

\[
\sup_{\tau \in N_\epsilon} \left| \frac{\partial}{\partial \delta} \left( c_{j+1}(\tau) - c_j(\tau) \right) \right| = O(j^{-1-\varsigma} + j^{\epsilon-2} \log j),
\]

\[
\sup_{\tau \in N_\epsilon} \left| \frac{\partial^2 c_j(\tau)}{\partial \delta^2} \right| = O(j^{\epsilon-1} \log^2 j),
\]

\[
\sup_{\tau \in N_\epsilon} \left\| \frac{\partial c_j(\tau)}{\partial \varphi} \right\| = O(j^{\epsilon-1}),
\]

\[
\sup_{\tau \in N_\epsilon} \left| \frac{\partial^2}{\partial \delta^2} \left( c_{j+1}(\tau) - c_j(\tau) \right) \right| = O(j^{1-1-\varsigma} + j^{\epsilon-2} \log^2 j),
\]

\[
\sup_{\tau \in N_\epsilon} \left\| \frac{\partial}{\partial \varphi} \left( c_{j+1}(\tau) - c_j(\tau) \right) \right\| = O(j^{\max(\epsilon-2, -1, -\varsigma)}),
\]

\[
\sup_{\tau \in N_\epsilon} \left\| \frac{\partial^2 c_j(\tau)}{\partial \varphi \partial \varphi'} \right\| = O(j^{\epsilon-1}),
\]

\[
\sup_{\tau \in N_\epsilon} \left\| \frac{\partial^2 c_j(\tau)}{\partial \varphi \partial \delta} \right\| = O(j^{\epsilon-1} \log j),
\]

\[
\sup_{\tau \in N_\epsilon} \left\| \frac{\partial^2}{\partial \varphi \partial \varphi'} \left( c_{j+1}(\tau) - c_j(\tau) \right) \right\| = O(j^{\max(\epsilon-2, -1, -\varsigma)}),
\]

\[
\sup_{\tau \in N_\epsilon} \left\| \frac{\partial^2}{\partial \varphi \partial \delta} \left( c_{j+1}(\tau) - c_j(\tau) \right) \right\| = O(j^{-1-\varsigma} + j^{\epsilon-2} \log j).
Acknowledgments. We thank the Associate Editor and two referees for constructive comments that have improved the presentation. We also thank Søren Johansen and Morten O. Nielsen for helpful comments. Some of the second author’s work was carried out while visiting Universidad Carlos III, Madrid, holding a Cátedra de Excelencia.

SUPPLEMENTARY MATERIAL

Supplement to “Gaussian pseudo-maximum likelihood estimation of fractional time series models” (DOI: 10.1214/11-AOS931SUPP; .pdf). The supplementary material contains a Monte Carlo experiment of finite sample performance of the proposed procedure, an empirical application to U.S. income and consumption data, and the proofs of the lemmas given in Section 5 of the present paper.
