Loss of Muscleblind-like 1 (Mbnl1) is known to alter Clc-1 splicing to result in myotonia. Mbnl1ΔE3ΔE2/Mbnl3ΔE2 mice, depleted of Mbnl1 and Mbnl3, demonstrate a profound enhancement of myotonia and an increase in the number of muscle fibers with very low Clc-1 currents, whereas gClmax values approach ~1 mS/cm², with the absence of a further enhancement in Clc-1 splice errors, alterations in polyA site selection or Clc-1 localization. Significantly, Mbnl1ΔE3ΔE2/Mbnl3ΔE2 muscles demonstrate an aberrant accumulation of Clc-1 RNA on monosomes and on the first polysomes. Mbnl1 and Mbnl3 bind Clc-1 RNA and both proteins bind Hsp70 and eEF1A, with these associations being reduced in the presence of RNA. Thus binding of Mbnl1 and Mbnl3 to Clc-1 mRNA engaged with ribosomes can facilitate an increase in the local concentration of Hsp70 and eEF1A to assist Clc-1 translation. Dual depletion of Mbnl1 and Mbnl3 therefore initiates both Clc-1 splice errors and translation defects to synergistically enhance myotonia. As the HSA model for myotonic dystrophy (DM1) shows similar Clc-1 defects, this study demonstrates that both splice errors and translation defects are required for DM1 pathology to manifest.

Research in context: Myotonic Dystrophy type 1 (DM1) is a dominator disorder resulting from the expression of expanded CUG repeat RNA, which aberrantly sequesters and inactivates the muscleblind-like (MBNL) family of proteins. In mice, inactivation of Mbnl1 is known to alter Clc-1 splicing to result in myotonia. We demonstrate that concurrent depletion of Mbnl1 and Mbnl3 results in a synergistic enhancement of myotonia, with an increase in muscle fibers showing low chloride currents. The observed synergism results from the aberrant accumulation of Clc-1 mRNA on monosomes and the first polysomes. This translation error reflects the ability of Mbnl1 and Mbnl3 to act as adaptors that recruit Hsp70 and eEF1A to the Clc-1 mRNA engaged with ribosomes, to facilitate translation. Thus our study demonstrates that Clc-1 RNA translation defects work coordinately with Clc-1 splice errors to synergistically enhance myotonia in mice lacking Mbnl1 and Mbnl3.

1. Introduction

Myotonic Dystrophy type 1 (DM1) is an autosomal dominant disorder resulting from the expansion of a non-coding CTC repeat sequence located in the 3′ untranslated region of DMPK (Brook et al., 1992; Harper, 2009). In DM1, expanded CUG repeat RNAs (CUGexp) aberrantly sequester and disable the muscleblind-like (MBNL) family of splice regulators (Fardaei et al., 2002; Dansithong et al., 2005). Significantly, either CUGexp expression or the depletion of Mbnl1 in mouse models has been shown to result in Clc-1 RNA splice defects and myotonia (Mankodi et al., 2002; Kanadia et al., 2003). This and other lines of evidence have lead DM1 to be considered as a spliceopathy (Ranum and Cooper, 2006). Other studies have implicated the muscleblind proteins in RNA transport, protein secretion and polyadenylation (Adereth et al., 2005; Wang et al., 2012; Batra et al., 2014). However the mechanisms whereby the Mbnl proteins mediate these functions and the role of these novel functional aspects of the Mbnl proteins in disease initiation has yet to be fully understood. In this study we show that the coordinate loss of Mbnl1 and Mbnl3 results in a synergistic enhancement of myotonia and a sharp increase in the number
of muscle fibers with extremely low chloride currents. We demonstrate that this synergism does not result from an enhancement in Clc-1 splice errors, alterations in polyA site selection or Clc-1 localization but rather reflects the aberrant accumulation of Clc-1 mRNA on monosomes and the first polysomes in muscles lacking Mbnl1 and Mbnl3. The observed Clc-1 translation errors reflect the ability of Mbnl1 and Mbnl3 to act as adapters, recruiting Hsp70 and eEF1A, to Clc-1 mRNA engaged with ribosomes to facilitate translation. These results therefore demonstrate that Clc-1 RNA translation defects work coordinately with Clc-1 splice errors to synergistically enhance myotonia in mice lacking Mbnl1 and Mbnl3. As similar defects are observed in the HSAΔ DM1 mouse model, where CUGexp aggregate and disable the Mbnl proteins, this study shows that both splice errors and translational defects are required for key features of DM1 pathology to fully manifest.

2. Materials & Methods

2.1. Ethics Statement

All experiments were performed in accordance with the institutional guidelines of the University of Southern California, Los Angeles, University at Buffalo, Buffalo New York and the University of California, Los Angeles. The protocols were approved by the Institutional Animal Care and Use Committee at the University of Southern California, Los Angeles (Protocol number: 10347).

2.2. Muscle Physiology

Contractile properties, electromyography and muscle histology were studied using standard procedures (Reddy et al., 1996; Personius and Arbas, 1998; Personius and Sawyer, 2006). Electrophysiological methods were similar to those described previously (DiFranco et al., 2011). Further details for electrophysiology, solutions and data acquisition are provided in Supplementary Information.

2.3. RNA Analysis

RNA isolation, splicing assays and RT-qPCR analysis were carried out primarily as described in Dansithong et al. (2005). Soleus polyribosomes were prepared according to a previously described protocol (Darnell et al., 2006). Electrophysiological methods were similar to those described previously (DiFranco et al., 2011). Further details for electrophysiology, solutions and data acquisition are provided in Supplementary Information.

2.4. Purification and Mass Spectrometric Analysis of MBNL3 Complexes

HEK293 cell lines expressing Flag-MBNL3 were generated by transfection of a pCDNA3.1-Flag-MBNL3 vector. Experimental details, including purification and mass spectrometric analysis of MBNL3 complexes are provided in Supplementary Information.

2.5. 3′RACE and PCR

For 3′RACE, total RNA was reverse transcribed using 3′RACE System for Rapid Amplification of cDNA Ends kits (Life Technologies, USA) with the adapter primer (AP-3′RACE: 5′-AAG CAG TGG TAA CAA CGC AGA GTA CTI TTT TTT TTT TTT TTT TT TTT VN-3′). Target cDNAs were amplified by PCR and nested PCR with gene-specific forward primers and the amplification primer (AP: 5′-AAG CAG TGG TAA CAA CGC AGA GT-3′). The relative band intensities were measured by densitometry analysis using Gene Tool (Syngene Inc., USA). To identify the Poly(A) sites, bands were excised and extracted using gel extraction kit (Qiagen, USA). Extracted DNAs were cloned into pGEM-T Easy Vector (Promega, USA) according to the manufacturer’s protocol. The DNA inserts were sequenced using the customized sequencing primers, T7 and SP6 promoter sequencing primers (Integrated DNA Technologies Inc., USA). The gene-specific forward primers and sequencing primers are as listed in Table S1.

3. Results

3.1. Development of Mbnl2GT2/GT2 and Mbnl3ΔE2 Mice

We developed 129sv Mbnl2 gene trap (Mbnl2GT2/GT2) mice derived from a BayGenomic ES cell line in which a retroviral β-geo gene trap is integrated downstream of Mbnl2 exon 2 (Fig. 1A–C). Chimeric animals derived from targeted 129sv ES cells were bred to 129sv wild type animals to derive 129sv Mbnl2GT2/GT2 mice. Analysis of genotype ratios of the progeny of Mbnl2 GT2/GT2 crosses did not reveal an Mbnl2GT2/GT2 lethal phenotype. In the Mbnl2GT2/GT2 mice transcription beyond the polyA site in the β-geo cassette in conjunction with the absence of the utilization of the β-geo splice acceptor site can result in the production of the normal transcript. Therefore we measured Mbnl2 levels using the MB2a monoclonal antibodies (Holt et al., 2009) and observe that Mbnl2 levels were decreased by ~85% in Mbnl2GT2/GT2 mice (Fig. 1D).

In parallel experiments we developed male Mbnl3ΔE2 and female Mbnl3ΔE2/ΔE2 mice in which exon 2 of the X-linked Mbnl3 gene was replaced by a Neomycin expression cassette (Fig. 1E & F). Exon 2 encodes the translation start site for the full-length 38 kD Mbnl3 protein (Mbnl338kD). Chimeric animals derived from targeted 129sv ES cells were bred to 129sv wild type animals to derive Mbnl3ΔE2/ΔE2 mice. Analysis of genotype ratios of the progeny of male Mbnl3ΔE2 and female Mbnl3ΔE2/ΔE2 mice did not reveal a homozygous mutant lethal phenotype. For simplicity, male and female mice lacking Mbnl3 exon2 are indicated as Mbnl3ΔE2.

Poulos et al. have described a C57BL/6 mouse strain in which Mbnl3 exon 2 was deleted (Poulos et al., 2013). These authors identified a 27 kD Mbnl3 isoform (Mbnl327kD), resulting from the use of a second translation start site in the C57BL/6 Mbnl3 exon 2. In their study, deletion of Mbnl3 exon 2 resulted in the loss of the full-length Mbnl338kD protein and retention of the truncated Mbnl327kD isoform (Poulos et al., 2013). We developed polyclonal antibodies using an Mbnl3 C-terminal peptide as previously described (Poulos et al., 2013) to characterize Mbnl3 expression in our 129sv Mbnl3ΔE2 mouse strain. Consistent with the results of Poulos et al., we observe loss of the full-length Mbnl338kD protein and retention of the truncated Mbnl327kD isoform in Mbnl3ΔE2 male and female Mbnl3ΔE2/ΔE2 placenta, a tissue that expresses high levels of Mbnl3 (Fig. 1G & H). Previous studies have shown elevated levels of Mbnl3 mRNA in stem cells and in multiple tissues during embryogenesis with diminished expression in adult human and mouse tissues (Fardaei et al., 2002; Poulos et al., 2013). RT-PCR analyses demonstrate detectable Mbnl3 exon 2 RNA expression in the C57BL6 and the 129sv adult wild type skeletal muscles but not in Mbnl3ΔE2 skeletal muscles (Figs. 11 and S1 & S2).

3.2. Mbnl2GT2/GT2 and Mbnl3ΔE2 Skeletal Muscles Do Not Show DM1 Specific Splice Defects

Mbnl2GT2/GT2 and Mbnl3ΔE2 lower limb muscles were dissected and the RNA from these tissues was examined for DM1 specific splice defects in a sample set of four RNAs, Ldhl, Clc-1, mTitin and Atp2a1 (Lin et al., 2006). In these experiments no significant change in the splicing of these RNAs in Mbnl2GT2/GT2 and Mbnl3ΔE2 skeletal muscles was observed when compared with wild type controls (Fig. S3). In parallel experiments no overt changes in muscle structure or function were detected.

3.3. Mbnl1ΔE1/ΔE3|Mbnl2GT2/GT2 Mice Demonstrate a Lethal Phenotype

To test the combinatorial effects of dose reductions in Mbnl1 and Mbnl2 we examined the genotypes of the progeny from an Mbnl1ΔE1/ΔE3 X Mbnl2GT2/GT2 cross. Mbnl1ΔE1/ΔE3 mice, in which a Neomycin cassette replaces Mbnl1 exon 3, are a gift of Dr. Swanson and have been previously
described by Kanadia et al., (2003). These animals were backcrossed onto a 129sv background for 4 generations prior to use in our experiments. Mbnl2^{GT2/GT2/Mbnl1} animals were not observed in the ~300 progeny examined, consistent with the lethality of the Mbnl1^{ΔE3/ΔE3}/Mbnl2-GT2/GT2 genotype.

### 3.4. Mbnl1^{ΔE3/ΔE3}/Mbnl3^{ΔE2} Mice Show Enhanced Myotonic Activity

In contrast to the lethal phenotype observed in the Mbnl2^{GT2/GT2}/Mbnl1^{ΔE3/ΔE3} animals, dual loss of Mbnl1 and Mbnl3 results in viable Mbnl1^{ΔE3/ΔE3}/Mbnl3^{ΔE2} animals that demonstrate a synergistic enhancement of skeletal muscle myotonia. As reported previously for the vastus muscle, runs of myotonic activity were observed in both the EDL and soleus muscles following needle insertion in Mbnl1^{ΔE3/ΔE3} mice with myotonic activity averaging at 3.07 ± 1.46 s in the EDL and 3.98 ± 2.10 s in the soleus (mean ± SEM, Tables 1 & 2) (Kanadia et al., 2003). In striking contrast, the length of myotonic activity was four to ten folds greater in Mbnl1^{ΔE3/ΔE3}/Mbnl3^{ΔE2} mice with average run lengths of 17.1 ± 3.88 s in the EDL and 32.3 ± 26.7 s in the soleus (mean ± SEM, Tables 1 & 2). The longest run of myotonic activity detected from Mbnl1^{ΔE3/ΔE3} and Mbnl1^{ΔE3/ΔE3}/Mbnl3^{ΔE2} mice is shown in Fig. 2A & B. The runs show the characteristic waxing/waning amplitude and frequency of myotonic electrical activity with the longest run lengths being 81.5 s and 26 s for Mbnl1^{ΔE3/ΔE3} and Mbnl1^{ΔE3/ΔE3}/Mbnl3^{ΔE2} mice, respectively.

Table 1

| Genotype                  | Muscle wt (mg) | EMG run length (s) | n   |
|---------------------------|----------------|--------------------|-----|
| Wild type                 | 6.31 ± 0.45    | 0.19 ± 0.03        | 9   |
| Mbnl1^{ΔE3/ΔE3}           | 7.78 ± 1.14    | 3.98 ± 2.10        | 8   |
| Mbnl2^{GT2/GT2}           | 7.17 ± 0.60    | 0.13 ± 0.01        | 5   |
| Mbnl1^{ΔE2}               | 7.57 ± 0.20    | 0.19 ± 0.03        | 6   |
| Mbnl2^{GT2/GT2}/Mbnl1^{ΔE2} | 5.80 ± 0.49    | 32.3 ± 26.7        | 4   |
| Mbnl1^{ΔE3/ΔE3}/Mbnl2^{GT2/GT2} | 5.86 ± 0.55   | 0.26 ± 0.03        | 7   |
| Mbnl1^{ΔE3/ΔE3}           | 8.25 ± 0.95    | 0.26 ± 0.05        | 3   |

p-Value *0.254

# < 0.001

(*) One-way ANOVA and Student t-tests with Bonferroni correction were used to determine paired differences between Mbnl genotype and wild type mice. (#) ANOVA on ranks with Dunn's post-hoc analysis was used for data with non-normal distribution. Bold indicates the statistically significant (p < 0.05).
Dunn’s post-hoc analysis was used for data with non-normal distribution. Bold indicates the statistically sign
tificantly different genotypes (Table 2).

3.5. Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 Mice Show Diminished Force Production

To test the effect of Mbnl dose reductions on specific force we measured maximal isometric specific force produced by the EDL muscle in wild type, Mbnl1ΔE3/ΔE3, Mbnl2ΔT2GT2/T2, Mbnl3ΔE2, Mbnl1ΔE3/ΔE3/Mbnl3ΔE2, Mbnl2ΔT2GT2/T2, Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3/Mbnl2ΔT2GT2/T2 mice. In these experiments, animal weight and EDL muscle weight were similar across all experimental groups (Table 2). Reduced force generation per cross sectional area (CSA) is only seen in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice when compared to wild type controls (one-way ANOVA, p = 0.0018), with Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice showing an intermediate reduction in force and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice showing a further diminishment of specific force (Specific force decreased 29.4% and 38.8% compared to wild type mice for Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice, respectively) (Fig. 2D). Mbnl1ΔE3/ΔE3/Mbnl2ΔT2GT2/T2 mice demonstrate mild weakness, suggesting that complete loss of Mbnl1 is necessary to result in significant loss of muscle force production.

Reduced force production in both Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice was seen at stimulation frequencies between 65–200 Hz. The similar shapes of the force-frequency curves (Fig. 2E) demonstrate that depletion of Mbnl1 or Mbnl1 and Mbnl3 do not affect the stimulation frequency necessary to produce maximal force production. These data suggest limited changes in the distribution of muscle fiber-types between Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice. As seen for maximal specific force, muscle force production followed a single 0.2 ms stimulation (twitch force, Pt) was reduced only in Mbnl1ΔE3/ΔE3 Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3/Mbnl2ΔT2GT2/T2 mice (one-way ANOVA, p = 0.027) (Table 2). Consistent with maximal specific force measurements, twitch force was modestly decreased in Mbnl1ΔE3/ΔE3 Mbnl2ΔT2GT2/T2 animals, with intermediate and maximal reduction in this series being observed in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice, respectively (Pt decreased 26.2% and 29.3% compared to wild type mice for Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice, respectively). Finally, no differences in the extent of muscle fatigue following 3 min of contraction at a 1/3 duty cycle was seen between genotypes further supporting limited changes in the distribution of muscle fiber-types in these genotypes (Table 2).

3.6. Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 Muscles Demonstrate Centralized Nuclei, Atrophic Fibers and Regions of Potential Fibrosis

EDL muscle sections from wild type, Mbnl1ΔE3/ΔE3, Mbnl2ΔT2GT2/T2, Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice were examined for myopathic changes subsequent to H&E stains (n = 3 mice per genotype). Mbnl2ΔT2GT2/T2 and Mbnl3ΔE2 mice show no histopathological changes. As previously reported Mbnl1ΔE3/ΔE3 mice demonstrate mild myopathy with regions of muscle fibers containing centralized nuclei (Kanadia et al., 2003). In contrast, muscle sections from Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice demonstrate some centralized nuclei, areas of very small atrophied fibers and regions of potential fibrosis (Fig. 2F). Average muscle fiber perimeter was 127 ± 3, 113 ± 7, 111 ± 15, 128 ± 40, and 138 ± 9 μm for wild type, Mbnl1ΔE3/ΔE3, Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 Mbnl2ΔT2GT2/T2 and Mbnl3ΔE2 mice, respectively. No difference was seen between any Mbnl deficient genotypes and wild type mice, however a trend towards muscle fiber CSA reduction was observed in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice, with an opposing trend of an increase in muscle fiber CSA observed in Mbnl2ΔT2GT2/T2 and Mbnl3ΔE2 mice (Frequency histograms of muscle fiber CSA and perimeter are shown in Fig. S4).

3.7. Clc-1 Immunohistochemistry in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3 Muscles

To decipher the mechanism underlying the enhanced myotonia observed in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice Clc-1 protein expression was examined by semi-quantitative immunofluorescence studies. Immunofluorescence analyses were utilized, as commercially available anti-C1-antibodies are unable to detect chloride channels by Western blot analyses. Clc-1 protein expression was identified by immunofluorescence using antibodies against the C terminus (CLC1 1-16 Alpha Diagnostic) and imaged by confocal microscopy. Since the intensity of Clc-1 immunofluorescence was relatively low, the confocal pin-hole was opened to 1.12 airy units to improve image brightness. Images were not deconvoluted to better identify receptor localization (Fig. 2G). The images observed using this protocol closely resemble confocal images of Ca₃.1 and Ca₃.2 Ca²⁺ expression in skeletal muscle (Jefftinija et al., 2007). As a first attempt to quantify Clc-1 expression, we measured Clc-1 immunofluorescence in 15 membrane regions for each confocal image (80 μm² ovars). The grayscale intensity of Clc-1 membrane immunolabeling was decreased in Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 muscles compared to wild type, Mbnl2ΔT2GT2/T2 and Mbnl3ΔE2 muscles (p < 0.001). Specifically, average gray scale values were 36 ± 3, 24 ± 1, 20 ± 1, 38 ± 3, and 39 ± 4 GSE for wild type, Mbnl1ΔE3/ΔE3 Mbnl1ΔE3/ΔE3/Mbnl3ΔE2, Mbnl2ΔT2GT2/T2 and Mbnl3ΔE2 mice, respectively. Thus Clc-1 protein expression appeared to be consistently reduced in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice when compared to wild type, Mbnl2ΔT2GT2/T2 and Mbnl3ΔE2 animals (n = 3 mice per genotype, Fig. 2G).

3.8. Chloride Currents Recorded in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 Fibers are Smaller Than Those of Mbnl1ΔE3/ΔE3 and Wild Type Fibers

Examination of chloride currents (ICl) was carried out subsequently to assess potential functional differences between Mbnl1ΔE3/ΔE3, Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 mice. Since the total ICl recorded from a single muscle fiber depends on its physical dimensions (length and radius), in these experiments we normalized the raw currents by both the fibers’ surface area (μm²) and capacitance (A/F). As our previous work has shown that a large fraction of ICl arises from the T tubule system (TTS) of adult mice (DiFranco et al., 2011), the latter normalization would take into account the contribution of the TTS to the total membrane area of a fiber. ICl records in response to the 3-pulse protocol obtained
from a wild type (129SV) fiber are shown in Fig. 3A. These currents show the canonical features of ICl that have previously been reported for adult wild type C57BL6 mice (DiFranco et al., 2011). Specifically, immediately following maximal activation during a long depolarization to +60 mV (pre-pulse), ICl records during test pulses show the typical inward rectification pattern with smaller steady outward currents (Fig. 3A, blue, gold, pink, and dark cyan traces) in response to depolarizing pulses, and larger transient inward currents with voltage-dependent deactivation rates (Fig. 3A, red, green, blue, orange and purple traces) in response to hyperpolarizing pulses. In the wild type 129sv fiber, the peak ICl in
response to a −120 mV pulse \([\text{peak ICl}_{\text{max}}] = −817 \mu \text{A/cm}^2 (−147 \text{ A/F})\), which is comparable to the −710 ± 58 \mu \text{A/cm}^2 (137 ± 11 \text{ A/F}; mean ± SEM), obtained under the same conditions and age, in wild type C57BL6 mice (DiFrancesco et al., 2011). Consistent with previous results in fibers from immature (9–14 days) Mbnl1ΔE3/ΔE3 mice (Lueck et al., 2007), our ICl records in fibers from adult (3–4 months) Mbnl1ΔE3/ΔE3 mice are generally smaller than those from wild type fibers (Fig. 3A & B). However, for the Mbnl1ΔE3/ΔE3 fiber shown in Fig. 3B the [peak ICl]max was −551 \mu \text{A/cm}^2 (−118 A/F), which represents a reduction of only 33% with respect to the wild type fiber shown in Fig. 3A. Average values for [peak ICl]max are −770 ± 34 \mu \text{A/cm}^2 (−156 ± 8 A/F; n = 16) and −507 ± 28 \mu \text{A/cm}^2 (−116 ± 7 A/F; n = 19) for fibers from wild type and Mbnl1ΔE3/ΔE3 mice, respectively. From these values, a 34% reduction is calculated.

Unlike ICl from Mbnl1ΔE3/ΔE3 fibers, currents from Mbnl3−/− fibers were not altered; the [peak ICl]max in Mbnl3−/− fibers was −799 ± 26 \mu \text{A/cm}^2 (−169 ± 6 A/F; n = 37), which is not significantly different (p > 0.3) from the average values in wild type mice. Since Mbnl1ΔE3/ΔE3 mice display more marked myotonia than Mbnl1ΔE3/ΔE3 animals, we tested if the severity of the myotonia results from further impairments in ICl in Mbnl1ΔE3/ΔE3/Mbnl3−/− animals. This would be particularly intriguing since fibers from Mbnl3−/− mice have normal ICl. Fig. 3C shows that, while the main features of the ICl records are preserved, the overall magnitudes of the currents are further reduced in fibers from Mbnl1ΔE3/ΔE3/Mbnl3−/− mice when compared to those from Mbnl1ΔE3/ΔE3/Mbnl3+/− fibers (Fig. 3B). The [peak ICl]max in the Mbnl1ΔE3/ΔE3/Mbnl3−/− fiber in Fig. 3C is −412 \mu \text{A/cm}^2 (−107 A/F), representing −50% of the current in wild type mice in Fig. 3A. A comparable and significant (p < 0.05) reduction was found for the average peak ICl in 16 fibers from Mbnl1ΔE3/ΔE3/Mbnl3−/− mice (−410 ± 55 \mu \text{A/cm}^2, or −90 ± 14 A/F) with respect to those from wild type mice. The additional 13% reduction in peak Mbnl1ΔE3/ΔE3/Mbnl2−/− ICl with respect to Mbnl1ΔE3/ΔE3 fibers, is statistically significant (p < 0.05).

3.9. Voltage-Dependence of ICl in Wild Type, Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3−/− Fibers

In order to further establish the comparative differences in the functional expression of Clc-1 in Mbnl mutant mice, we investigated whether the voltage-dependence of the peak (instantaneous) and steady-state I–V plots of ICl were preserved in wild type, Mbnl1ΔE3/ΔE3, Mbnl3−/− and Mbnl1ΔE3/ΔE3/Mbnl3−/− animals. Panels D–F in Fig. 3 show that peak ICl plots (black symbols) in all three mouse strains display similar inward rectification properties. Importantly, the magnitudes of the ICl are differentially affected in the Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3−/− mice when compared to wild type mice. Specifically, Fig. 3D reveals almost identical properties for wild type (black closed symbols and solid line) and Mbnl3−/− (black open symbols and dashed line) fibers. In contrast, peak data from Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3−/− mice must be scaled by 1.46 and 1.88 factors (respectively), in order to become superimposable with those from wild type animals (not shown). Likewise, the steady-state ICl plots (red symbols and lines) showing the characteristic inverted bell shape of Clc-1 can be scaled using similar proportions with those of their respective peak ICl in order to match the data from wild type mice. Thus these data demonstrate that the functional expression of Clc-1 is normal in Mbnl3−/− mice, but reduced to −34% and −47% in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3−/− mice, respectively (p < 0.05). Taken in conjunction with the Clc-1 immunohistochemistry analyses, these data support the model that the intrinsic properties of Clc-1 channels are not altered in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3−/− mice and that the deficiency in current magnitude is related to a diminished density in channel expression.

3.10. Reduction of Maximal Slope Conductance in Mbnl1ΔE3/ΔE3 and Mbnl1ΔE3/ΔE3/Mbnl3−/− Fibers

A more comprehensive way to demonstrate the reduction in the expression of Clc-1 channels in Mbnl mutant muscles is to evaluate the maximal (limiting) slope conductance (gClmax), as obtained from the instantaneous I–V plots of ICl. Fig. 3G shows that, in correspondence with the data from the previous plots, gClmax is large in wild type (7.0 ± 0.31 mS/cm2, or 1.39 ± 0.09 mS/A; n = 16) and Mbnl3−/− (7.4 ± 0.27 mS/cm2, or 1.57 ± 0.06 mS/A; n = 37), minimal in Mbnl1ΔE3/ΔE3 (3.5 ± 0.52 mS/cm2, or 0.80 ± 0.12 mS/μA; n = 16), and intermediate (4.9 ± 0.29 mS/cm2, or 1.2 ± 0.06 mS/μA; n = 18) in Mbnl1ΔE3/ΔE3−/− mice. In addition, gClmax from fibers of Mbnl1ΔE3/ΔE3/Mbnl3−/− mice were significantly smaller than those from Mbnl1ΔE3/ΔE3 mice. The statistical significance between gClmax values was independent of the normalization factor (area or capacitance).

3.11. Frequency Distribution of gClmax in Fibers from Mbnl Mutant Mice

We have shown that myotonia as reported by EMG is more pronounced in Mbnl1ΔE3/ΔE3/Mbnl3−/− mice when compared to Mbnl1ΔE3/ΔE3 mice and that the average peak ICl (and [peak ICl]max) is smaller in the Mbnl1ΔE3/ΔE3/Mbnl3−/− muscles when compared with Mbnl1ΔE3/ΔE3−/− muscles. Nevertheless, the data on the functional expression of Clc-1 channel reported here are incompatible with the classic claim that the genesis of myotonia requires reductions in gCl larger than 70% (Furman and Barchi, 1978). In order to examine this apparent discrepancy, we compared the frequency distribution of gClmax in fibers from the wild type and the Mbnl strains (Fig. 4). Each dataset was fitted with a normal distribution (shown with solid lines) and for the purpose of comparison, the normal curve fitted to the data from the wild type mice is shown superimposed to the data from the Mbnl mutant strains. It can be observed that the gClmax histograms for fibers of wild type and Mbnl3−/− mice (Fig. 4A and B) are very similar to each other, and the medians are centered at almost identical average values. These results are in agreement with both the lack of myotonia and the normal ICl in Mbnl3−/− mice. In contrast, when the data obtained from wild type and Mbnl1ΔE3/ΔE3 mice are compared (Fig. 4C), the average gClmax is clearly shifted to the left, and that there are a significant number of fibers with very small gClmax values that are outside the normal distribution of wild type animals. We propose that, although on-average gClmax is not drastically reduced in Mbnl1ΔE3/ΔE3 mice, the small but significant numbers of severely affected fibers may explain the mild myotonia in these animals. This explanation is consistent with the observation that the Mbnl1ΔE3/ΔE3/Mbnl3−/− mice display both much stronger myotonia...
and show a much more significant shift of the average $g_{\text{Cl}_{\text{max}}}$ to lower values (Fig. 4D). Furthermore, a significant number of fibers from $\text{Mbnl1}^{\Delta\text{E3}/\Delta\text{E3}}/\text{Mbnl3}^{\Delta\text{E2}}$ mice have extremely low values of $g_{\text{Cl}_{\text{max}}}$, reaching values as low as 1/7 of the average for wild type mice. Such values were never detected in the other 3 strains examined, and may readily explain why the $\text{Mbnl1}^{\Delta\text{E3}/\Delta\text{E3}}/\text{Mbnl3}^{\Delta\text{E2}}$ mice display much more pronounced myotonia than the $\text{Mbnl1}^{\Delta\text{E3}/\Delta\text{E3}}$ animals.

3.12. $\text{Mbnl1}^{\Delta\text{E3}/\Delta\text{E3}}/\text{Mbnl3}^{\Delta\text{E2}}$ Muscles Do Not Show an Enhancement in Clc-1 Splice Defects or Further Reductions in Clc-1 RNA Steady-State Levels When Compared to $\text{Mbnl1}^{\Delta\text{E3}/\Delta\text{E3}}$ Muscles

As the myotonia observed in DM1 has been hypothesized to result primarily from Clc-1 splice errors and a concomitant reduction of RNA steady-state levels due to nonsense mediated decay of aberrantly
spliced Clc-1 RNAs (Mankodi et al., 2002) we tested if Clc-1 splice defects are enhanced in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 mice. As expected, we observed enhanced (~50%) inclusion of Clc-1 exon 7a in Mbnl1ΔE3ΔE4 mice when compared with wild type muscles. Significantly, Clc-1 exon 7a inclusion was not enhanced in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles when compared to Mbnl1ΔE3ΔE4 muscles (Fig. 5A). These results were confirmed by qPCR, which showed that the steady-state mRNA levels of Clc-1 isoforms including exon 7a and exon 7 in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles was similar to that observed in Mbnl1ΔE3ΔE4 (Fig. S5A). To test the possibility that splice defects other than aberrant Clc-1 exon 7a inclusion are enhanced in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 mice, we checked exon inclusion for all Clc-1 exons (Fig. S5B). Additional splice defects including retention of intron 2 and inclusion of exon 8a were observed in Mbnl1ΔE3ΔE4 skeletal muscles (Fig. S5A), but no enhancement of these splice errors was observed in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles when compared to Mbnl1ΔE3ΔE4 muscles. Consistent with the absence of an enhancement in Clc-1 splice defects in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles, steady-state Clc-1 mRNA levels are similar in Mbnl1ΔE3ΔE4 and Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles (Fig. 5B). In addition, no difference in Clc-1 hnRNA levels was observed in Mbnl1ΔE3ΔE4 and Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles (Figs. 5C and SSC & D). These data support the hypothesis that aberrant chloride channel splicing is necessary but insufficient for myotonia to fully manifest in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 mice.

3.13. Clc-1 RNA Translation Is Altered in Mbnl1ΔE3ΔE4/Mbnl3ΔE2 Muscles

The observation that Mbnl1ΔE3ΔE4/Mbnl3ΔE2 muscles do not display enhancement in Clc-1 splice defects or differences in mRNA steady-state levels when compared with Mbnl1ΔE3ΔE4 muscles suggest that Clc-1 expression might be regulated at the translation level. A recent study has shown that Mbnl3ΔE2ΔE3 co-fractionates with polysomes in C2C12 cells, suggesting that Mbnl3ΔE2ΔE3 may be involved in translation of Mbnl3ΔE2ΔE3 target RNAs (Poulos et al., 2013). In contrast, Mbnl1 has been shown to associate with smaller mRNP particles, but not with polysomes in HeLa cells (Onishi et al., 2008). To clarify whether Mbnl1 associates with polysomes in mouse skeletal muscle, we performed polysome analysis using sucrose gradient fractionation. As reported for HeLa cells, we found that the majority of Mbnl1 co-fractionates with smaller mRNP particles. However in skeletal muscle Mbnl1 was also detected in polysome fractions (Fig. S6). This observation was confirmed by polysome disruption with EDTA treatment, which resulted in a shift of Mbnl1 in polysome factions to lower density fractions (Fig. S6). These data suggested that Mbnl1 and Mbnl3 might be involved in the translational regulation of Clc-1 mRNA. Polyribosomes were therefore prepared using soleus muscles dissected from wild type (n = 4), Mbnl1ΔE3ΔE4 (n = 5), Mbnl3ΔE2 (n = 3) and Mbnl1ΔE3ΔE4/Mbnl3ΔE2 (n = 3) mice on 20–50% density sucrose gradient and polyribosome profiles were analyzed by A260 absorbance (Fig. 6A) and non-denaturing agarose gel electrophoresis (Fig. S7). Relative Clc-1 mRNA distribution in each of the 16 polysome sucrose gradient fractions from wild type, Mbnl1ΔE3ΔE4, Mbnl3ΔE2 and Mbnl1ΔE3ΔE4/Mbnl3ΔE2 soleus muscles was analyzed by qPCR. Relative Clc-1 mRNA distribution was not significantly different in Mbnl1ΔE3ΔE4 and Mbnl3ΔE2 muscles when compared to wild type muscles. However Mbnl1ΔE3ΔE4/Mbnl3ΔE2 skeletal muscles showed a very distinctive Clc-1 mRNA distribution pattern when compared to wild type and Mbnl1ΔE3ΔE4 muscles and demonstrated that Clc-1 mRNA is highly enriched in fraction numbers 6 and 7 that correspond to monosomes and the first polysomes respectively as shown in
the A254 traces of total RNA distribution (Fig. 6A & B). To further test whether the Clc-1 polypyrimidine stretch pattern observed in Mbnl1ΔE3/ΔE2 mice is specific, we analyzed the Clc-1 mRNA distribution pattern subsequent to EDTA treatment by qPCR. As expected, EDTA treatment resulted in a shift of the Clc-1 mRNAs to lighter fractions by poly- somonucleation (Fig. 6C). Western blot analysis did not show significant differences in Gapdh levels in the mouse genotypes studied (Fig. S8). Consistent with this observation relative Gapdh mRNA distribution in the 16 polysome gradient fractions from wild type, Mbnl1ΔE3/ΔE2, Mbnl3ΔE2 and Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 skeletal muscles were not significantly different (Fig. 6D). To determine whether the distinct Clc-1 mRNA distribution pattern in Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 skeletal muscles is also observed with the overexpression of CUG in vivo, we analyzed the HSA4b mouse model for myotonic dystrophy, which expresses 250 CUG repeats repeated in the 3′ UTR of the human skeletal actin trans- gene that results in the aberrant sequestration of the Mbnl proteins (Mankodi et al., 2002; Lin et al., 2006). As expected, we observed enhanced inclusion of Clc-1 exon 7a in HSA4b muscles when compared to wild type muscles (Fig. 6E). However, in contrast to a 7 fold increase in Mbnl1ΔE3/ΔE2/Mbnl3ΔE2 skeletal muscles (Fig. S5B), the HSA4b muscles showed a 2.6 fold increase in the steady-state mRNA levels of the Clc-1 isoforms including exon 7a when compared to wild type muscles. Consis- tent with this observation, steady-state Clc-1 mRNA levels in the HSA4b skeletal muscles were reduced by ~30% when compared to wild type muscles (Fig. 6F), in contrast to the ~50% reduction in Mbnl1ΔE3/ΔE3/ΔE2 s skeletal muscles (Fig. 5B). The reduced severity of Clc-1 RNA processing defects may reflect the less than complete sequestration of the Mbnl pro- teins by CUG in the HSA4b mice. Polyribosome profiles from ~2 month old wild type (n = 6) and HSA4b (n = 6) soleus muscles were analyzed by A254 absorbance (Fig. 6G) and relative Clc-1 mRNA distribution in each of the 16 polysome gradient fractions was analyzed by qPCR (Fig. 6H). Similar to Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 skeletal muscles, Clc-1 mRNA was significantly enriched in fraction number 7 in HSA4b skeletal muscle when compared to wild type muscle (Fig. 6H). These data strongly

Fig. 5. Chloride channel RNA splicing and steady-state RNA levels are not significantly different in Mbnl1ΔE3/ΔE2 and Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 muscles. (A) Alternative splicing was analyzed for Clc-1 in wild type, Mbnl1ΔE3/ΔE2, Mbnl3ΔE2, and Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 soleus muscles (n = 3) by RT-PCR. Exon numbers, position of primers and expected band sizes are indicated. The alternatively spliced exons are shown as blue boxes. Exon numbers are annotated based on Refseq from UCSC genome browser (NCBI37/mm9). Band intensities were quantified by densitometry. No statistical significance was observed for Clc-1 alternative splicing between Mbnl1ΔE3/ΔE2 and Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 soleus muscles. (B–C) RNA from wild type, Mbnl1ΔE3/ΔE2, Mbnl3ΔE2, and Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 soleus muscles (n = 6) were subjected to qPCR to measure Clc-1 mRNA (B) and hnrRNA (C) steady-state levels. Clc-1 mRNA and hnrRNA levels were normalized to that of Gapdh. Location of Clc-1 exon-exon boundary spanning primers and exon–intron boundary spanning primers used for mRNA and hnrRNA level measurements are shown. PCR amplification in the absence of reverse transcriptase was used to confirm the absence of genomic DNA contaminants (Fig. S5). Error bars represent standard error of mean (SEM). Each sample was replicated in triplicate. p-values were determined by paired student’s t-test.* and *** indicates p < 0.05 and p < 0.0001, respectively.

Fig. 6. Clc-1 expression is regulated at the translational level in Mbnl1ΔE3/ΔE3/ΔMbnl3ΔE2 muscles (A) Each aliquot (containing 13 OD at A250mm) of polyribosomal preparations from wild type (n = 4), Mbnl1ΔE3/ΔE3 (n = 5), Mbnl3ΔE2 (n = 3), and Mbnl1ΔE3/ΔE2/Mbnl3ΔE2 (n = 3) soleus muscles was fractionated by centrifugation at 40,000 rpm for 2 h at 4 °C using a 20%–50% w/w linear density gradient of sucrose. A254 traces of total RNA distributions are shown. Gradient fraction numbers, 405, 605, 805 and polysomes are indicated. (B) cDNAs were prepared using equal volumes of RNA from each of the 16 sucrose gradient fractions. Clc-1 mRNA distribution in each fraction derived from wild type, Mbnl1ΔE3/ΔE3, Mbnl3ΔE2, and Mbnl1ΔE3/ΔE2/Mbnl3ΔE2 soleus muscles was analyzed by qPCR. (C) Clc-1 mRNA distribution in each fraction analyzed by qPCR from muscle extracts treated with EDTA. (D) Gapdh mRNA distribution in each of the 16 sucrose gradient fractions from wild type, Mbnl1ΔE3/ΔE3, Mbnl3ΔE2 and Mbnl1ΔE3/ΔE2/Mbnl3ΔE2 soleus muscles was analyzed by qPCR.Data are plotted as percentages of the total mRNA on the gradient. Error bars represent the standard error of mean (SEM). p-Values were calculated using two-way ANOVA multiple comparisons. * and ** indicates p < 0.05, p = 0.0001 and p < 0.0001, respectively. (E) Alternative splicing was analyzed for Clc-1 in wild type and HSA4b soleus muscles (n = 3) by RT-PCR. Exon numbers, position of primers and expected band sizes are indicated. The alternatively spliced exons are shown as blue boxes. Exon numbers are annotated based on Refseq from UCSC genome browser (NCBI37/mm9). Band intensities were quantified by densitometry. The state-steady mRNA level of Clc-1 isoforms including exon 7a and exon 7b in wild type and HSA4b mice (n = 3) was measured by qPCR. Expression level of Clc-1 isoforms including exon 7a was normalized to that of Gapdh. Error bars represent standard error of mean (SEM). Each sample was replicated in triplicate. p-values were determined by paired Student’s t-test. *** indicates p < 0.0001. (F) RNA from wild type and HSA4b soleus muscles (n = 3) were subjected to qPCR to measure Clc-1 mRNA steady-state levels. Clc-1 mRNA levels were normalized to that of Gapdh. Error bars represent standard error of mean (SEM). Each sample was replicated in triplicate. p-values were determined by paired Student’s t-test. *** indicates p < 0.0001. (G) A254 traces of total RNA distributions from wild type and HSA4b soleus muscles are shown. Gradient fraction numbers, 405, 605, 805 and polysomes are indicated. (H) Clc-1 mRNA distribution in each of the 16 sucrose gradient fractions from wild type and HSA4b soleus muscles (n = 6) was analyzed by qPCR. Error bars represent the standard error of mean (SEM). p-Values were calculated using two-way ANOVA multiple comparisons. * indicates p < 0.05.
suggest that Clc-1 expression is regulated at the translational level and that both Mbnl1 and Mbnl3 are required for optimal Clc-1 mRNA translation. Recent study has demonstrated that depletion of Mbnl proteins leads to misregulation of alternative polyadenylation (APA) events (Batra et al., 2014) and another study has reported that depletion of Mbnl1 and 2 results in mislocalization of many mRNA (Wang et al., 2012), implicating the Mbnl proteins in regulation of APA and localization of mRNAs. As these events could impact translation, we checked whether poly(A) site shifts occurred in Clc-1 mRNA in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 skeletal muscles. We identified a novel proximal poly(A) start site in the 3' UTR of Clc-1 gene and a distal poly(A) start site downstream of the Clc-1 3' UTR both by restriction enzyme digestion and sequencing (Figs. S9 & S10). However, no significant poly(A) site shift was observed in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 skeletal muscles when compared to wild type muscles (Fig. S11). Therefore, it is unlikely that the translation defects observed in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 skeletal muscles result from alternative poly(A) selection. To
test the possibility that mislocalization of CIC-1 mRNA in Mbnl1<sup>ΔE3/ΔE3</sup> / Mbnl3<sup>ΔE2</sup> skeletal muscles leads to a translation defect, we measured the relative CIC-1 mRNA levels in subcellular fractions that were isolated from wild type and Mbnl1<sup>ΔE3/ΔE3</sup>/Mbnl3<sup>ΔE2</sup> skeletal muscles. However, we observed no significant difference in the CIC-1 mRNA levels in the nuclear, cytoplasmic and membrane fractions from wild type and Mbnl1<sup>ΔE3</sup>/ Mbnl3<sup>ΔE2</sup> mice (Fig. S12).

3.14. Mbnl1 and Mbnl3 Bind CIC-1 mRNA

We analyzed CIC-1 mRNA sequences to identify the putative Mbnl1 and Mbnl3 binding sites by using SMap (Akerman et al., 2009; Ho et al., 2004; Paz et al., 2010; Poulos et al., 2013). We identified 21 and 34 binding sites in the coding region, whereas only 2 and 3 binding sites were found in 3’ UTR for Mbnl1 and Mbnl3, respectively (Fig. S3A). We then determined whether Mbnl1 and Mbnl3 directly binds CIC-1 mRNAs (3545nts) by using in vitro RNA binding assays. 32P-labeled CIC-1 (1–1994), CIC-1 (1945–3545) and CIC-1 (3’ UTR) transcripts showed similar binding to recombinant His-Mbnl1 and His-Mbnl3, but not to GST. As expected, however, 32P-labeled CIC-1 (3’ UTR) transcripts showed very weak binding to Mbnl1 and Mbnl3 proteins when compared to Clc-1 (1–1994) and Clc-1 (1945–3545) transcripts (Fig. S13B). Neither His-Mbnl1 nor His-Mbnl3 bound to 32P-labeled Gapdh transcripts, indicating that the binding between CIC-1 mRNA and Mbnl1 and Mbnl3 is specific (Fig. 7A).

3.15. Mbnl1 and Mbnl3 Demonstrate RNA Regulated Association with Hsp70 and eEF1A

As we observed that the depletion of Mbnl1 and Mbnl3 results in CIC-1 mRNA accumulation in monosomes and the first polysome fractions (Fig. 6), we tested if these proteins act as adaptors to recruit factors required for translation. To identify proteins associated with Mbnl3, we established cell lines that stably express Flag-tagged Mbnl3. We then purified and identified Mbnl3-associated factors by Mass spectrometry analysis (Fig. 7B). The identified Mbnl3-associated factors were compared with the Mbnl1-associated factors (Paul et al., 2011). We found that two factors, Hsp70 and eEF1A, associate with both Mbnl1 (Fig. S14) and Mbnl3 (Fig. 7B) and the interaction of these factors with Mbnl1 and Mbnl3 was validated by coimmunoprecipitation (Fig. 7C & D). To check whether RNA mediates these interactions, we performed coimmunoprecipitation assays both in the presence and absence of RNase A. Interestingly, the interaction between Hsp70 and Mbnl1 and Mbnl3 increased in the presence of RNase A. A similar increase in the interaction between eEF1A and both Mbnl1 and Mbnl3 was observed in the presence of RNase A (Fig. 7C & D). Our data suggest that the Mbnl proteins may behave as adaptors that serve to recruit protein cargoes to target RNAs. Proteins bound to Mbnl 1 and Mbnl3, which either remains bound to the Mbnl proteins upon target RNA binding or that are released at the site of target RNA binding, can serve to increase the local concentration of these proteins at the site of target RNA binding. To test this idea, we performed coimmunoprecipitation assays in the presence of added CUG repeat-encoding RNAs, which are known to strongly bind both the Mbnl1 and the Mbnl3 proteins. We observed that binding of Hsp70 to the Mbnl proteins decreases as the amount of the CUG transcripts increase (Fig. 7E & F). Binding to Hsp70 decreased more sharply for Mbnl3 when compared to Mbnl1 in the presence of CUG repeats (Fig. 7E & F). Thus the enhanced interaction between the cargo protein, Hsp70 and Mbnl1 and Mbnl3 in the presence of RNase may reflect such reversible and competitive binding. The kinetics of cargo protein release may however be influenced by the binding affinity or location of the binding sites on the target RNAs. These results suggest that Hsp70 and Mbnl-target RNAs bind reversibly and competitively to Mbnl protein. As both Mbnl1 and Mbnl3 bind CIC-1 mRNAs and depletion of these proteins results in an accumulation of CIC-1 mRNA with monosomes and the first polysome fractions, our data suggests that Mbnl1 and Mbnl3 binding to CIC-1 mRNA engaged in ribosomes may facilitate an increase in the local concentration of Hsp70 and eEF1A to enhance translation (Fig. 7C).

4. Discussion

To test the role of the Mbnl family of proteins in skeletal muscle function we have developed and examined transgenic mouse strains that show single and combinatorial deficits in the three muscleblind proteins, Mbnl1, Mbnl2 and Mbnl3. In contrast with the Mbnl1<sup>ΔE3/ΔE3</sup> mice, which have previously been described to recapitate some features of DM1 muscle disease (Kanadia et al., 2003), Mbnl2<sup>ΔE2/ΔE2</sup> and Mbnl3<sup>ΔE2</sup> mice are viable and show no overt skeletal muscle pathology. Dual deficits of Mbnl1 and Mbnl2 results in a lethal phenotype reminiscent of the increase in the spontaneous abortion rate reported in DM1. An increase in the severity of the skeletal muscle disease observed with the depletion of both Mbnl1 and Mbnl3 manifests as a synergistic enhancement of myotonia, reductions in force production and alterations in histopathology observed as an increase in atrophic fibers with a potential for increased fibrosis and central nuclei. Consistent with enhanced myotonia, examination of chloride channel function demonstrates both a reduction in the magnitude of average peak IC<sub>1</sub> in fibers from Mbnl1<sup>ΔE3/ΔE3</sup>/Mbnl3<sup>ΔE2</sup> mice and a significant increase in the numbers of fibers having extremely low values of g<sub>Clmax</sub> that approach ~1 mS/cm<sup>2</sup> as compared with an average of 7 mS/cm<sup>2</sup> for wild type mice. The enhancement in chloride channel dysfunction in Mbnl1<sup>ΔE3/ΔE3</sup>/Mbnl3<sup>ΔE2</sup> mice does not result from an increase in the severity of CIC-1 RNA splice errors, a further decrease in CIC-1 RNA steady-state levels, altered polyA start sites or CIC-1 mislocalization when compared with Mbnl1<sup>ΔE3/ΔE3</sup> animals, but rather from CIC-1 mRNA translation defects. Our data suggest that Mbnl1 and Mbnl3 act as adaptors to recruit Hsp70 and eEF1A to CIC-1 RNA engaged with ribosomes to facilitate translation.

The muscleblind protein family encodes two pairs of zinc fingers, each containing three cysteines and one histidine residue, with other regions being conserved to varying degrees (Fardaei et al., 2002). These proteins show specialized patterns of expression, with Mbnl1 levels remaining unchanged during myoblast differentiation and Mbnl2 and Mbnl3 levels showing elevated expression in myoblasts and diminishing with differentiation (Holt et al., 2009). Mbnl1 and Mbnl2 RNAs are detected in adult muscle, heart, brain, kidney, liver and pancreas. Mbnl3 RNA expression is low in adult tissues (Fardaei et al., 2002). All three proteins sequester strongly in CUG foci in DM1 cells (Fardaei et al., 2002).

As we do not observe significant mortality in litters derived from Mbnl1<sup>ΔE3ΔE3</sup> x Mbnl2<sup>ΔE2ΔE2</sup> crosses, our data support the model that combinatorial deficits of Mbnl1 and Mbnl2 results in an embryonic lethal phenotype. These data are reminiscent of the high rate of fetal loss resulting from spontaneous abortion that is documented in DM1 (Jaffe et al., 1986). Thus complete sequestration of the MBNL1 and MBNL2 proteins in CUG foci may lead to embryonic lethality with less complete sequestration in various cell types and organ systems leading to viable but impaired individuals exhibiting a variety of pathological features (Charizanis et al., 2012; Lee et al., 2013).

Mbnl3 and Mbnl1 loss results in a synergistic interaction manifesting as enhanced myotonia, diminished force production and a histopathology of central nuclei, atrophic fibers and regions of potential fibrosis, in skeletal muscle. These results are particularly intriguing, as Mbnl3 loss does not result in significant muscle pathology. To examine the mechanism underlying this synergy we focused our studies on the 4 to 10 fold enhancement in myotonia observed in the limb muscles of mice lacking Mbnl1 and Mbnl3 when compared to animals lacking only Mbnl1. As previous studies have implicated chloride current deficits in the development of myotonia in the JSK<sup>ΔE8</sup> mouse model and mice lacking Mbnl1 (Kanadia et al., 2003; Mankodi et al., 2002), we
Fig. 7. Mbnl1 and Mbnl3 bind Clc-1 mRNA and associate with Hsp70 and efF1A. (A) In vitro transcribed 32P-labeled Clc-1 (1–1944) and Clc-1 (1945–3545) RNAs (Clc-1 mRNA: 3545 nts) were incubated with either recombinant His-Mbnl1 or Mbnl3 to test binding of Clc-1 RNA with Mbnl1 and Mbnl3. Recombinant GST protein and 32P-labeled Gapdh transcripts were used as controls for the Mbnl proteins and 32P-labeled Clc-1 transcripts, respectively. The radioactive RNA-protein complex was visualized by autoradiography. Asterisk (*) shows non-specific binding. 32P-labeled Clc-1 (1–1944), Clc-1 (1945–3545) and Gapdh transcripts were visualized by 3% acrylamide gel electrophoresis and autoradiography. Purified recombinant GST, His-Mbnl1 and His-Mbnl3 were confirmed by commassie blue staining (CBS). RNA and protein sizes are indicated. (B) Affinity purification of Mbnl3-interacting proteins. Flag-tagged Mbnl3 was stably expressed in HEK293 cells and subjected to immunoprecipitation utilizing anti-Flag antibodies. The copurified proteins were separated by 4–20% gradient SDS-PAGE. Specific bands were excised and analyzed by LC/MS–MS analysis. Identified Mbnl3-interacting proteins are indicated. (C–D) Interaction of endogenous Hsp70 and efF1A with Mbnl3. One half of the whole cell extracts prepared from the control and stable cell lines expressing Flag-Mbnl3 were pre-treated with RNase A (1 mg/ml) for 15 min at 37 °C. Untreated and RNase A treated extracts were immunoprecipitated with anti-Flag antibodies and analyzed by Western blotting using anti-Flag, Hsp70 and efF1A antibodies as indicated. Band intensities were quantitated by densitometry and normalized to that of the immunoprecipitated Mbnl3 proteins with anti-Flag antibodies. Asterisks indicate nonspecific bands. Lanes 1–13 represents 10% of the input. Error bars represent the standard error of mean (SEM). * and ** indicates p < 0.05 and p < 0.001, respectively. (E-F) One half of the whole cell extracts prepared from the stable cell lines expressing Flag-Mbnl1 or Flag-Mbnl3 were pre-treated with various concentrations (200, 400 and 800 ng) of in vitro transcribed CUG transcripts (E) for 30 min at 4 °C. Untreated and CUG transcript-treated extracts were immunoprecipitated with anti-Flag antibodies and analyzed by Western blotting using anti-Flag, Hsp70 and efF1A antibodies (F). Asterisks indicate IgG heavy chain. Lanes 1 represents 10% of the input. (G) Clc-1 expression is regulated at the transcription level by Mbnl1 and Mbnl3.
combination with one or more deficits resulting from Mbnl1 depletion, synergize to facilitate diminished chloride channel function. Previous studies have demonstrated that unlike the truncated 27 kDa Mbnl3 isoform, the full-length 38 kDa Mbnl3 isoform cofractionates with polysomes (Poulos et al., 2013). In this study, we observe that a fraction of the Mbnl1 protein also cofractionates with polysomes. These observations suggested that the enhanced reduction of Clc-1 function in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2/ΔE2 muscles may result from Clc-1 mRNA translation defects. Polyribosome profiling analysis shows that Mbnl1 and Mbnl3 depletion results in significant accumulation of Clc-1 mRNA in gradient fractions corresponding to the monosome and the first polysome when compared to wild type and Mbnl1ΔE3/ΔE3 ani-
mals. Interestingly, although ~57% of Clc-1 mRNA in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 muscles is associated with monosomes and single polysomes, 37% of the Clc-1 mRNA associated with heavier polysome fractions, indic-
ating that this translation defect does not completely block the Clc-1 RNA transition to heavier polysome fractions. Thus rather than an all or none effect this defect may increase the chance of diminished Clc-1 protein production and serve to explain the increase in the number of fibers showing very low chloride currents in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 muscles.

The translation defects observed for the Clc-1 mRNA appear to be specific as similar alterations were not observed for the Gapdh mRNA. Consistent with this idea, we observe that Mbnl1 and Mbnl3 specifically bind to the Clc-1 mRNA when examined using in vitro RNA binding as-
says. As depletion of either Mbnl1 or Mbnl3 does not show the promi-
udent defects in Clc-1 RNA distribution on polysome fractions observed in muscles lacking both proteins, it is likely that Mbnl1 and Mbnl3 may have partially redundant functions in Clc-1 mRNA translation reg-
ulation. It is therefore conceivable that translation related factors associ-
ated with both Mbnl1 and Mbnl3 could be involved in the translation regulation of the Clc-1 mRNA.

In the next set of experiments we identified Hsp70 and eEF1A as Mbnl1 and Mbnl3-interacting factors. These results are significant be-
cause Hsp70 is known to play a key role in protein synthesis by associ-
ation with nascent polypeptides (Beckmann et al., 1990). As the nascent polypeptide chain emerges into the cytosol, interaction with Hsp70 is cru-
cial for the continuous transport of the polypeptide through the ribo-
some channel into the cytosol (Nelson et al., 1992). Hsp70 deficits can there-
fore cause the nascent polypeptide to interfere with translation by clogging the ribosome channel. Thus Hsp70 deficits can perturb pro-
tein synthesis at the translation step, which can result in reduced ac-
cessibility of the EF1A-aminoacyl-tRNA complex to the ribosome (Nelson et al., 1992). In this context, it is interesting to speculate on the mechanism by which Clc-1 expression is regulated in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 muscles. As Mbnl1 and Mbnl3 bind Clc-1 mRNA specifically and because the interaction between Mbnl1 and Mbnl3 with Hsp70 and eEF1A increases subsequent to treatment of RNase A or an increase in the concentration of CUG repeat encoding transcripts, Mbnl1 and Mbnl3 may act as adaptors, that serve to increase the local concentration of Hsp70 and eEF1A on Clc-1 mRNAs engaged with ribosomes (Fig. 7C–G). Therefore, Mbnl1 and Mbnl3 depletion can result in the redu-
tion of the local concentration of Hsp70 and eEF1A and consequent-
ly shift the Clc-1 mRNA distribution towards the lighter polysome frac-
tions. As these events may serve to shift the equilibrium towards less efficient translation rather than a complete stalling of translation, they can provide an explanation for the increase in the frequency with which muscle fibers with low chloride currents are encountered in Mbnl1ΔE3/ΔE3/Mbnl3ΔE2 muscles. Taken together our data demonstrate that Mbnl1 and Mbnl3 deficits profoundly enhance myotonia and that the mechanisms driving this enhancement are not only Clc-1 splice er-
rors resulting from Mbnl1 loss, but also Clc-1 translation defects occur-
ring from the dual loss of Mbnl1 and Mbnl3. Importantly, as both Clc-1 splice defects and an aberrant accumulation of Clc-1 RNA on mon-
somes and the first polysomes is observed in the iΔSAPΔ DM1 model, where a similar increase in a subpopulation of muscle fibers with low chloride currents has been reported (DiFranco et al., 2013), our data demonstrate that splice defects work coordinate with translation errors for key features of myotonic dystrophy pathalogy to fully manifest.

Author Contributions

SR, JLV, KEP, LC and JC conceived and designed the experiments; SR, JC, KEP, MD, WD, CY, SS, DMD, DBB, JLV, LC performed experiments and analyzed the data; SR, JLV, MD, KEP and JC wrote the manuscript; SR, JLV, DMD, KEP, MD, WD, CY, SS DMD, DBB, LC, and JLV discussed and reviewed the manuscript.

Conflict of Interest

Conflicts of interest: none.

Acknowledgments

We thank Dr. Jennifer Darnell for valuable comments, Dr. Maurice Swanson for the Mbnl1ΔE3/ΔE3 mouse, Matthew Bancone for assistance with muscle fiber CSA assessment and Dr. Glenn Morris, Dr. Ian Holt and the Muscular Dystrophy Association Monoclonal Antibody Re-
source (http://www.glennmorris.org.uk/mabs.htm) for the MB2a monoclonal antibodies. Research reported in this publication was sup-
ported by NIH/NINDS award number NS060839 (SR) and NIH/NIAMs award numbers AR047664, AR54816, and AR041802 (JLV). The content is solely the responsibility of the authors and does not necessarily repre-
sent the official views of the National Institutes of Health.

Appendix A. Supplementary Data

Supplementary data to this article can be found online at http://dx.
