1. Background
Hepatitis C is a global health problem. According to the World Health Organization (WHO) estimation, about 170 million patients with hepatitis C virus (HCV) infection live in the world. Around 70 percent of patients with HCV infection develop chronic hepatitis, which 30% of them progress to end stage liver disease (1). Approximately 30% of HCV-infected individuals resolve infection spontaneously and the remaining progress to chronic hepatitis C (CHC) (2, 3). Acute hepatitis C (AHC) can be presented by acute hepatitis presentation such as jaundice and liver enzymes elevation, but most patients spend this phase without any symptoms and as a result, diagnosis in this phase is difficult. According to different studies, viral and host factors have been associated with HCV spontaneous and treatment-related clearance (4, 5). Several genome-wide association studies (GWAS) demonstrated that rs12979860 single nucleotide polymorphism (SNP) in the intron 1 of Interferon lambda 4 (IFNL4) gene was associated with treatment response in patients with chronic HCV infection (6-8). Previously, rs12979860 SNP was recognized as the polymorphism of IL28B gene (6). Interferon lambda genes located on chromosome 19 belong to the family of type III Interferons. Different interferon lambda genes are recognized including IFNL1 (IL29), IFNL2 (IL28A), IFNL3 (IL28B), and IFNL4, which all have been demonstrated to possess antiviral activity in-vivo and in-vitro (9). Different studies showed that the rs12979860 C allele favors response to antiviral treatment of chronic HCV infection (10, 11). Frequency of C allele varies in different ethnicities and it was shown to be higher in Caucasians than Africans (4). There is little data regarding the impact of host genetics on spontaneous clearance (SC) of acute hepatitis C from Iran and the Middle East countries.

2. Objectives
The aim of the present study was to identify the impact of rs12979860 SNP on spontaneous clearance of hepatitis C infection.

3. Materials and Methods
3.1. Study Population
To address directly the role of the rs12979860 SNP on...
HCV spontaneous clearance (SC), we designed a case-control study on 91 patients with spontaneous HCV clearance and 259 ones with persistent HCV infection as the case and control groups, respectively. The included individuals all had positive result for anti-HCV antibody (anti-HCVAb) and referred to Tehran Blood Transfusion Hepatitis Clinic from 2011 to 2013. All HCV SC and CHC cases did not receive antiviral therapy for hepatitis C infection before including in the study. The case and control groups were matched regarding sex and age. Patients with coinfection of hepatitis B virus and human immunodeficiency virus were excluded from the study. HCV SC condition was confirmed by anti-HCVAb positivity and subsequent two negative HCV RNA tests by a minimum of 6-month interval; whereas, persistence of HCV RNA in serum more than six months in the presence of anti-HCVAb was considered as CHC. A questionnaire consisted of demographic data and HCV-related risk factors were filled for every patient. All study participants provided informed consent and the study design was approved by the Ethics Committee of Iranian Blood Transfusion Organization. The study protocol conforms to the ethical guidelines of the 1975 declaration of Helsinki.

3.2. Virological Assessments

Anti-HCVAb was assessed using Elecsys® Anti-HCV II assay (Roche Diagnostics). Furthermore, HCV RNA in serum was assessed using COBAS® TaqMan® HCV Test v2.0 (Roche Diagnostics) according to the manufacturer’s instructions. For HCV genotyping, the core gene of HCV was amplified by QIAGEN OneStep RT-PCR Kit (Qiagen, Hilden, Germany) followed by direct DNA sequencing procedure and phylogenetic analysis.

3.3. Genotyping of rs12979860 SNP

In this study, rs12979860 SNP was assessed as the most common IFNL polymorphism. The detailed protocol of polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method for genotyping of rs12979860 SNP was previously described (12). Genomic DNA was extracted from peripheral blood specimen using QIAamp® DNA Blood Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer’s instructions. The extracted DNA was amplified using following primers for rs12979860 SNP: 5’-GGGTCCTTGGCCGGAGTTGCT-3’ and 5’-GGGCTTGGCGAGGCTTGCT-3’. The temperature profile was consisted of 94°C for five minutes; followed by 35 cycles of 94°C for 20 seconds, 66°C for 20 seconds and 72°C for 20 seconds, followed by 72°C for five minutes. The PCR product of rs12979860 SNP was digested with Bsh1236I (BstUI) restriction endonuclease (Fermentas, Vilnius, Lithuania) which resulted in two 196 and 45 bp fragments in rs12979860 CC genotype, three 241, 196, and 45 bp fragments in rs12979860 CT genotype and a 241 bp fragment in TT genotype.

3.4. Statistical Analysis

Categorical variables were expressed by frequency and percentage. Continuous variables were expressed by mean ± standard deviation (SD). Comparison between categorical variables was performed using Fisher-exact test. P value below 0.05 was considered statistically significant. All statistical analyses were performed using SPSS software for Windows (SPSS, version 17).

4. Results

In this case-control study, 350 patients with positive result for anti-HCVAb were included. The mean ± SD age of the study population was 39.7 ± 10.4. Intravenous drug use (IDU) and non-IDU were the main HCV acquiring risk factors among our patients. We could not identify HCV genotypes in SC group because all of them referred after HCV clearance. HCV genotyping revealed HCV genotype 1 as the predominant genotype in patients with CHC followed by HCV genotype 3. The patients’ characteristics are summarized in Table 1. Among the SC cases, distribution of rs12979860 genotypes was as follows: 64 (70.3%) were CC, 26 (28.6%) were CT and 1 (1.1%) was TT, while among CHC patients, 95 (36.7%) were CC, 134 (51.7%) were CT and 30 (11.6%) were TT (P < 0.001) (Figure 1). In the dominant model (CC vs. CT+TT), the distribution of CC genotype in the SC group was around two folds of its distribution in the CHC group (P < 0.001, OR = 4.09, 95% CI = 2.44-6.86). Moreover, in the allelic model, the frequency of rs12979860 C allele was higher in SC group than the CHC group (P < 0.001) (Table 2).
null
serum level of IP-10 and IL28B SNPs can identify patients with AHC who are most likely to undergo HCV SC and those who progress to CHC and need early antiviral treatment. They found that IP-10 level was lower in patients who cleared HCV spontaneously (17). Gender had a great influence among factors affecting AHC outcome, which female patients had more chance for achieving HCV SC than the males (28). The study by van den Berg et al. (29) showed that SC status was more frequent in females with the favorable genotype for rs12979860 (CC) than females with the unfavorable genotypes (CT and TT). Several studies have shown that female gender and symptomatic acute hepatitis C were highly associated with HCV SC (30). A recent study in patients with acute HCV genotype 4 infection identified that IL28B CC genotype, female sex, robust T-cell responses, rapid decline in ALT and HCV RNA levels, and presence of jaundice were predictors of HCV SC (31). HCV genotype was another factor able to predict the outcome of AHC. According to the study by Grebely et al. (32) patients with HCV genotype 1 cleared HCV more frequently than those with other HCV genotypes. The route of HCV transmission may affect AHC outcome as well. A large population cohort study in the northeast of Iran showed that illicit drug use whether intravenous or non-intravenous was significantly correlated with CHC versus HCV SC. The rate of HCV SC in this study was about 38% (33). Grebely et al. (34) found that the rate of HCV SC was lower in illicit drug use and HIV coinfected. Shores et al. (35) observed that the rate of HCV SC in HIV-infected patients who acquired HCV from intravenous drug use was significantly lower than those with sexual transmission as the presumed route of HCV transmission. In addition, it was observed that the rate of HCV SC was up to 50% in children and women infected after RH immunization (28, 36). In the present study, all SC cases were included after HCV clearance, thus determination of HCV RNA level and HCV genotyping were impossible.

In conclusion, the present study confirmed the role of host immunity on outcome of viral infection by investigating the impact of IFNλ3-12979860 SNP on natural history of HCV infection. More large-scale multicentric longitudinal studies are needed to reliably evaluate the outcome of patients in acute hepatitis C phase regarding different host and viral factors.

Acknowledgements

We gratefully acknowledge The Hepatitis Clinic of Tehran Blood Transfusion Center and Middle East Liver Disease (MELD) Center staff. Furthermore, we would like to thank Dr. Kalhor Zadeh for her assistance in data collection.

Authors’ Contributions

Seyed Moayed Alavian, Bita Behnava and Maryam Keshvari: designed the study and contributed in sample collection; Heidar Sharafi and Ali Pouryasin: performed the study; Heidar Sharafi and Maryam Keshvari analyzed the data and wrote the paper.

Funding/Support

This study was supported by Armin Pathobiology Laboratory.
