Abstract

The present study investigated the anti-Toxoplasma effect of chitosan nanoparticles [CS NPs], spiramycin, spiramycin co-administered with metronidazole and spiramycin-CS NPs formulation on the parasite burden and histopathological changes in the liver, spleen and brain in experimentally infected mice. Seventy male Swiss albino mice were classified into seven equal groups: healthy control (I), infected untreated control (II), infected group receiving CS NPs (III), spiramycin administered infected group (IV), infected group receiving spiramycin-metronidazole (V), infected receiving 400 mg/kg spiramycin-CS NPs (VI) and infected treated with spiramycin-loaded CS NPs 100 mg/kg (VII). All groups were inoculated intraperitoneally with 2500 *T. gondii* tachyzoites RH strain except the healthy control group. All groups were sacrificed on the 8th day after infection. Density of the parasite and histopathological examination of the liver, spleen and brain of all treated mice revealed reduction in the mean tachyzoites count as well as decreased inflammation, congestion and necrosis within tissue sections. Spiramycin-loaded NPs displayed the highest significant reduction in the pathological insult trailed by spiramycin-metronidazole and CS NPs. In conclusion, spiramycin-loaded CS NPs showed a promising synergistic combination in the treatment of the histopathology caused by toxoplasmosis.

Introduction

Toxoplasmosis is a highly prevalent foodborne disease relating to the intracellular parasite *Toxoplasma gondii* [*T. gondii*]. It infects about one third of the population worldwide [Wohlfer et al. 2017]. The parasite exists in two distinct forms; a rapidly replicating invasive tachyzoite and a slowly replicating bradyzoite inside tissue cysts. *T. gondii* [RH strain] tachyzoites showed no potential for tissue cyst [bradyzoites] and oocysts formation in laboratory infected rats and mice [Dubey et al. 1999; Mordue et al. 2001; Asgari et al. 2013]. The faster replication of the tachyzoites leads to many pathological changes ranging from mild congestion to severe degeneration involving mainly the liver, spleen and brain [Unno et al. 2013; Fuentes-Castro et al. 2017].

Although many drugs are used for toxoplasmosis treatment, yet no definitive “gold standard” treatment has been available. Some medicines have been commonly used such as pyrimethamine-sulfadiazine, trimethoprim-sulfamethoxazole, pyrimethamine-clindamycin, azithromycin and traditional Chinese medicine. They may be poorly tolerated, have severe side effects and/or have poor tissue penetration. Thus, the uncertainty of their efficacy is still not resolved [Valentini et al. 2015; Wei et al. 2015].

Spiramycin is less toxic than other drugs and it is used for the treatment of *T. gondii* infection among human population and in the prevention of vertical transmission from mother to foetus in the first trimester of pregnancy. It is absorbed efficiently after oral intake and spreads quickly to blood and tissues [Shi et al. 2005]. Despite its significant tissue penetration, it reveals poor crossing of the blood brain barrier [BBB] owing to the presence of the efflux transporters for which spiramycin is a substrate [Grover and Benet, 2009]. For enhancement of its brain bypass, spiramycin could be co-administered with metronidazole to inactivate the efflux pumps present in the BBB [Chew et al. 2012].
In the search for new strategies that overcome the disadvantage of the used treatment regimens, it was found that application of nanomedicine improved the drug biodistribution, modified bioavailability and decreased toxicity [Assolini et al. 2017]. Numerous types of nanoparticles [NPs] such as silver and gold are used, but their use may be hampered by their toxic side effects, adding to their relatively higher production cost in comparison to the natural based NPs [Cameron et al. 2016; Benelli, 2018]. Chitosan [CS] is a normal non-toxic polysaccharide obtained from shells of crustaceans and molluscs by chitin deacetylation [Yong et al. 2015]. The advantages of CS make it the material of choice for NPs preparation in various fields. Its biocompatible, biodegradable, nontoxic nature and relatively low cost encourage its suitable applicability especially in developing countries. CS has been extensively known as an antimicrobial agent due to its intrinsic positive charge density and chelating capacity [Kong et al. 2010; Nehra et al. 2018; Ahmed et al. 2019]. Many studies have proven the therapeutic effectiveness of CS NPs against many protozoa, besides their use as vehicles to deliver anti-parasitic drugs to improve their efficacy. It is successfully used as anti-Cryptosporidium, anti-Trypanosoma, anti-Leishmania, anti-Plasmodium and anti-Toxoplasma in vivo and in vitro studies [Tripathy et al. 2012; Chaubey and Mishra, 2014; Unciti-Broceta et al. 2015; Teimouri et al. 2018; Ahmed et al. 2019]. Few studies have addressed the tissue injury caused by the parasite before and after treatment [Fuentes-Castro et al. 2017].

The present study is a continuation of our previous work that was conducted by Hagras et al. [2019], who reported that spiramycin-CS NPs formulation revealed the highest therapeutic outcome in acute experimental toxoplasmosis treatment compared to CS NPs, spiramycin and spiramycin co-administered with metronidazole. This study was designed to investigate the effect of these drugs on the parasite burden and pathological changes in the liver, spleen and brain in T. gondii [RH strain] infected Swiss albino mice.

**Materials And Methods**

Details of the methodology are presented in the work of Hagras et al. [2019].

**I. Parasite**

Briefly, the RH virulent strain of T. gondii was acquired from the Parasitology Department, Faculty of Medicine, Alexandria University, Egypt. The strain was conserved by successive intraperitoneal passage of tachyzoites in Swiss albino mice. The peritoneal fluid was obtained from sacrificed mice on the 4th day post-infection and washed three times with saline. A drop of the peritoneal exudates was added to the haemocytometer and the tachyzoites number was adjusted for mice infection.

**II. Drugs**

Blank chitosan nanoparticles [CS NPs], spiramycin, spiramycin-metronidazole and spiramycin-CS NPs formulation were administered from day one of infection for 7 days. The dose per mouse was adjusted and dissolved in 100 µl saline for oral administration.
II.1. Preparation of both spiramycin and spiramycin-metronidazole suspensions from tablets:

Spiramycin tablets and metronidazole tablets [Rovamycin® and Flagyl®-Sanofi Aventis Pharmaceutical Company, France] were purchased. Each tablet was weighed then crushed into powder. The active ingredient of each tablet was calculated according to its weight.

II.2. Preparation of CS NPs and spiramycin-loaded CS NPs:

Nanoparticles [NPs] were prepared and characterized by ionotropic gelation technique based on the interaction between the positive charge of amino groups of chitosan [CS] and the negative groups of sodium tripolyphosphate (TPP) [Hagras et al.2019].

III. Mice:

Seventy male Swiss Albino mice with a weight range of 20–25 grams were obtained from Medical Technology Center, Medical Research Institute, Alexandria University, Egypt. The study was approved by the ethics committee of the Medical Research Institute, based on international regulations of animal care.

IV. Experimental design [Figure 1]:

The mice were distributed into seven experimental groups (ten mice per each). T. gondii RH strain infection was induced by intraperitoneal mice injection with 2500 tachyzoites/100 µl saline/ mouse except the healthy controls [Araujo et al.1992; Ezz Eldin et al. 2015].

The groups were divided as follows:

- **Group I**: Healthy control.
- **Group II**: Infected untreated control, each mouse received 100 µl saline [the vehicle of the used drugs] orally.
- **Group III**: Infected mice received blank CS NPs at a dose of 30 mg/kg [Hagras et al. 2019].
- **Group IV**: Infected mice treated with spiramycin [Rovamycin®] at a dose of 400 mg/kg/day [Chew et al. 2012].
- **Group V**: Infected mice received a combination of metronidazole at a dose of 500 mg/kg followed by 400 mg/kg spiramycin after 30 minutes [Chew *et al.*, 2012].
- **Group VI**: Infected mice treated with spiramycin-CS NPs formulation at a dose of 400 mg/kg/day.
- **Group VII**: Infected mice treated with spiramycin-CS NPs at a dose of 100 mg/kg/day.

The mice were anaesthetized and sacrificed by cervical dislocation on the 8th day i.e., 24 hours after the seven days of treatment.
V. Determination of parasitic burden

Tachyzoites were counted in Giemsa-stained impression smears of liver, spleen and brain. The mean count was obtained from thirty oil immersion fields in each organ per each mouse [ten fields/ each slide and three slides/ each organ] [Eissa et al. 2012; Gaafar et al. 2014].

VI. Histopathological study

Specimens from the liver, spleen and brain were taken from all the groups and fixed in 10% formalin. They were dehydrated in an ascending series of ethyl alcohol [70%, 80%, 95% and 100%] then cleared in xylene. The samples were embedded in molten paraffin at 60°C for 1–2 hrs to form paraffin blocks. Block sections were cut using microtome. Each section was 4 µm thick. Two sections were prepared from the different organs of each mouse, they were mounted on slides, then left in the oven at 40°C to dry and fix on the slides. Slides were deparaffinized by dipping them in xylene followed by passing them in descending series of ethyl alcohol [100%, 95%, 80% and 70%] then rinsed with water for rehydration. Slides were stained with haematoxylin, rinsed under running water then counterstained with eosin. They were dehydrated using an ascending series of ethyl alcohol and then mounted in Canada balsam. Tissue sections of the liver, spleen and brain were examined under the microscope [Titford, 2006; Musumeci, 2014]

Statistical analysis

Differences were studied by Kruskal Wallis test using IBM SPSS software package version 20.0 [Armonk, NY: IBM Corp]. They were considered significant when $p < 0.05$ [Kotz et al. 2006; Kirkpatrick and Feeney, 2013].

Results

I. Parasite burden:

The infected untreated control group showed median parasite counts of 12, 8 and 3 / 30 oil immersion field (OIF) in liver, spleen and brain respectively. There was a significant reduction in parasite burden in the groups treated with spiramycin-CS NPs formulation in comparison to other groups [Figures 1–3].

II. Histopathological study:

II.1. Liver (Fig. 4)

Microscopic examination of sections of the liver from healthy control (group I) showed normal hepatic architecture divided into lobules. The hepatocellular cords were mostly one or two layers thick radiating from the central vein towards the periphery of the lobule. The normal hepatocytes were polygonal in shape with centrally placed round or oval dark violet nuclei and granulated eosinophilic cytoplasm. The
cords of hepatocytes were separated by blood sinusoids lined by endothelial cells (EC). At the periphery of the lobule, the portal triads showed no inflammatory cellular infiltrates [Figure 4.1].

In the infected untreated control (group II), microscopic examination of liver tissue revealed invasive tachyzoites aggregated among the hepatocytes. Markedly dilated and congested central veins and sinusoids with evident focal necrosis and inflammation. (Fig. 4.2)

The liver sections of CS NPs treated group (III) showed pseudocysts with necrotic tachyzoites. Residual apoptotic bodies of hepatic nuclei and degenerative hepatocytes with marked dilated congested central veins and sinusoids were noticed. Moreover, there was evidence of lobular inflammation [Figure 4.3].

In the treated spiramycin group (IV), microscopic examination of the liver demonstrated that the hepatocytes were large in size with large vesicular nuclei and vacuolar degeneration of cytoplasm. Marked dilated congested central veins and dilated sinusoids surrounded by necrotic hepatocytes with obvious inflammation [Figure 4.4].

The microscopic examination of spiramycin-metronidazole treated group (V), illustrated marked dilated sinusoids surrounded by moderate inflammatory infiltrate with interface hepatitis and moderate portal fibrosis. Most hepatocytes appeared intact but some of them were necrotic [Figure 4.5].

Spiramycin- CS NPs 400 mg/kg treated group (VI) revealed dilated sinusoids and absent inflammatory infiltrate [Figure 4.6].

The liver of spiramycin-CS NPs 100 mg/kg treated group (VII) demonstrated pseudocysts with necrotic tachyzoites. There was evidence of regenerative hepatocytes. Dilatation of central veins and sinusoids were observed with minimal inflammation formed of few perivascular macrophages [Figure 4.7].

II.2. Spleen (Fig. 5)

Microscopic examination of the spleen of the healthy control (group I) revealed well-organized white pulp (W) (containing lymphocytes) and red pulp (R) differentiated by trabecular muscles (TR) [Figure 5.1].

Infected untreated control (group II) spleen section showed pseudocysts containing tachyzoites. Marked disorganized architecture and extramedullary hematopoiesis with areas of necrosis were observed. There was an obvious decrease in lymphocyte counts and increase in histiocytes [Figures 5.2 and 5.3].

In CS NPs treated group (III), areas of macrophages loaded by tachyzoites were observed. Disorganized splenic architecture in addition to extramedullary hematopoiesis were evident in the red pulp [Figure 5.4].

The microscopic examination of spiramycin infected treated group (IV) illustrated pseudocysts containing necrotic tachyzoites and numerous apoptotic cells. Severe disorganized splenic architecture with enhancement of the inflammatory cells and reduction in the lymphocytes were observed [Figure 5.5].
The spleen of spiramycin-metronidazole treated group (V) demonstrated moderate disorganized architecture with extramedullary hematopoiesis and excess eosinophils [Figure 5.6].

In spiramycin-CS NPs 400 mg/kg treated group (VI), necrotic tachyzoites in pseudocysts in the red pulp and at the margin of regenerative lymphocytes of the white pulp were observed. Mild disorganized spleen architecture with evident tissue recovery and extramedullary hematopoiesis were noticed [Figure 5.7].

Spiramycin CS NPs 100 mg/kg treated group (VII) showed pseudocysts with necrotic tachyzoites. Moderate disorganized spleen architecture with regenerative white pulp forming well defined germinal centres as well as frequent epithelioid histiocytes were evident [Figure 5.8].

II.3. Brain (Fig. 6)

Examination of the brain cortex of the healthy control [group I] revealed normal architecture composed of neuroglial cells with ill-defined cytoplasm and pyramidal cells. Normal blood vessels were present [Figure 6.1].

In infected untreated control (group II), the cerebral cortex showed gliosis, apoptosis as well as perivascular and parenchymal inflammation [Figure 6.2].

The microscopic examination of CS NPs treated group (III) illustrated mild dilated blood vessels. Small pyramidal cells and others with vacuolated cytoplasm were noticed. Apoptosis and marked gliosis were observed [Figure 6.3].

In the spiramycin treated group (IV), the brain revealed the occurrence of perivascular inflammatory infiltrate, gliotic nodules and necrotic neurons [Figure 6.4].

In the brain of spiramycin-metronidazole treated group (V), no tachyzoites were detected. Mild congested blood vessels, moderate gliosis and ferrugination (mineralized bodies of necrotic neurons) were observed [Figure 6.5].

Spiramycin- CS NPs 400 mg/kg treated group (VI) revealed absence of tachyzoites with mild dilation of blood vessels. Normal neuroglial cells with no evidence of inflammation were observed [Figure 6.6].

In the brain of spiramycin-loaded CS NPs 100 mg/kg treated group (VII) spongiosis, moderate gliosis and apoptosis were seen. No inflammation was observed [Figure 6.7].

Discussion

Toxoplasmosis treatment is a worthy challenge to achieve, particularly that the parasite is intracellular and crosses the blood brain barrier [Briones et al. 2008].

To fulfil the present work, CS NPs, spiramycin, spiramycin co-administered with metronidazole and spiramycin-CS NPs were evaluated for treating acute toxoplasmosis regarding parasite load and
histopathology of the liver, spleen and brain in Swiss albino mice.

The parasite burden decreased in liver, spleen and brain among all treated mice in comparison to the infected untreated control. The least parasite load was obtained after the treatment with spiramycin-loaded NPs compared to the other groups regarding all the studied organs.

In the present work, histopathological study demonstrated severe tissue damage in the liver, spleen and brain of acute *T. gondii* infected untreated mice. Marked inflammation, congestion, areas of lytic necrosis and free tachyzoites within tissue sections were detected as compared to those of the healthy control and of the treated mice. Activated inflammatory cells that were attracted by the free tachyzoites, triggered the inflammatory response, causing cell lysis. Their effect incorporates with the mechanical damage produced by the tachyzoites. These findings coincide with various reports of previous studies [Unno et al. 2013; Fuentes-Castro et al. 2017].

All the used treatments [CS NPs, spiramycin, spiramycin co-administered with metronidazole and spiramycin-CS NPs] modulated the pathological effects in the liver, spleen and brain of mice infected with *T. gondii* RH strain. The various degrees of response were characterized by disappearance of necrosis and reduction of inflammation.

Concerning the liver of infected untreated mice, it was characterized by congested veins and sinusoids accompanied by lobular necrosis, vacuolar degeneration of hepatocytes and inflammatory infiltrate in both lobular and portal areas with interphase hepatitis. Free tachyzoites were seen in the necrotic foci. The findings agreed with those described by Unno et al.[2013] and Mady et al.[2016]. All treated groups showed reduction in the inflammatory infiltrate with fibrosis. Regeneration of hepatocytes was noted together with minimal mononuclear inflammatory infiltrate. In mice receiving spiramycin-metronidazole, residual portal and bridging fibrosis were noted. Interestingly, the groups of spiramycin-CS NPs 400 mg/kg treated and spiramycin-CS NPs 100 mg/kg showed nearly normal architecture with necrotic tachyzoites.

Regarding the spleen of the infected untreated group, there was disorganized architecture with areas of necrosis and absent germinal centers. Extramedullary hematopoiesis appeared with frequent megakaryocytes. This latter sign was previously described in the literature and was clarified by the fact that *T. gondii* induces systemic levels of IL-12 which promotes high level of extramedullary hematopoiesis [EMH] [Zaretsky et al. 2012]. In the spleen of the treated groups, extramedullary hematopoiesis persisted. However, in the groups treated with spiramycin-CS NPs 400 mg/kg and spiramycin-loaded CS NPs 100 mg/kg, the necrosis disappeared completely and restoration of close normal architecture was identified. There was regeneration of white pulp, well-structured lymphoid follicles with reactive germinal centers and healthy demarcated red pulp.

In the brain of the infected untreated mice, the injury was evidenced by astrocytic proliferation [gliosis] and scattered necrotic neurons. Perivascular inflammation, spongiosis and congestion were observed. Similar observations were reported by Parlog et al. [2015] and Fuentes-Castro et al. [2017]. Treatment
greatly reduced the inflammation; dead neurons were mineralized or replaced by gliotic nodules. Best results were seen in the group treated with spiramycin-CS NPs 400 mg/kg; normal neuroglial cells with no sign of inflammation were detected.

Conclusion: The most significant tissue regenerative effect in liver, spleen and brain with absence of living tachyzoites was noticed in the mice treated with spiramycin-CS NPs 400 mg/kg. Thus, it could be a promising treatment for toxoplasmosis due to its capability to penetrate the tissues and particularly the BBB.
