Background: This study was designed to investigate the role of a primary hyperoxidative stress in myocardial electrical remodeling using heterozygous heart/muscle-specific manganese superoxide dismutase-deficient (H/M-Sod2+/-) mice treated with L-buthionine-sulfoximine (BSO).

Methods and Results: Both H/M-Sod2+/- and wild-type (WT) mice were treated with intra-peritoneal BSO or saline for 7 days, and divided into 4 groups: H/M-Sod2+/-+BSO, WT+BSO, H/M-Sod2+/- control, and WT control. The ventricular effective refractory period (ERP) and the monophasic action potential duration (MAPD) were determined. Levels of oxidative stress, potassium channel-related molecules, and K+ channel-interacting protein-2 (KChIP2) were also evaluated. The H/M-Sod2+/-+BSO group exhibited markedly prolonged MAPD20, MAPD90 and ERP in comparison with the other groups (MAPD20: 14±1 vs. 11±1 ms, MAPD90: 77±7 vs. 58±4 ms, ERP: 61±6 vs. 41±3 ms, H/M-Sod2+/-+BSO vs. WT control; P<0.05). Mitochondrial superoxide and hydrogen peroxide formation in the myocardium increased in the H/M-Sod2+/-+BSO group in comparison with the WT+BSO group (P<0.05). Real-time RT-PCR and Western blotting revealed that Kv4.2 expression was downregulated in both BSO-treated groups, whereas KChIP2 expression was downregulated only in the H/M-Sod2+/-+BSO group (P<0.05).

Conclusions: BSO treatment caused hyperoxidative stress in the myocardium of H/M-Sod2+/- mice. Changes in the expression and function of potassium channels were considered to be involved in the mechanism of electrical remodeling in this model. (Circ J 2014; 78: 1950–1959)

Key Words: Electrical remodeling; K+ channel-interacting protein-2 (KChIP2); Potassium channel; Reactive oxygen species; Superoxide dismutase 2 (Sod2)

Oxidative stress has been considered to play a causative role in various cardiovascular diseases, such as reperfusion injury in ischemia,1–3 and myocardial injury in heart failure.4,5 More recently, a direct relationship between oxidative stress and electrical remodeling has also been suggested.6 We have previously documented that primary hyperoxidative stress produced electrical remodeling, which is characterized by MAPD90 prolongation, ERP shortening, and increased ventricular vulnerability in the glutathione-depleted systemic hyperoxidative rat.7 In that model, the hyperoxidative stress was produced by systemic glutathione-depletion, which was induced by the administration of L-buthionine-sulfoximine (BSO). In the previous model,7 the hyperoxidative stress was systemic and not restricted to the myocardial tissue, and primary changes due to its effects on the myocardium and secondary changes due to its effect on other organs and tissues such as neurohumoral reactions could not be distinguished. Therefore, the model is incomplete and not appropriate for evaluating the primary effect of oxidative stress on the electrical properties of the myocardium.

Editorial p 1834

Superoxide dismutase 2 (Sod2) is one of the enzymes that...
eliminates reactive oxygen species (ROS) in mitochondria, converting superoxide (O$_2^-$) to hydrogen peroxide (H$_2$O$_2$). Homozygous heart/muscle-specific manganese superoxide-deficient (HM-Sod2$^{-/-}$) mice have been reported to exhibit a dilated cardiomyopathy-like condition with dilated dimensions, a lower ejection fraction of the left ventricle and the destruction of myocardial tissue. They exhibit a 12.3-fold larger fibrotic area and a decreased expression of connexin 43 in their myocardium in comparison with age-matched wild-type (WT) mice. In contrast, heterozygous heart/muscle-specific manganese superoxide-deficient (HM-Sod2$^{+/-}$) mice exhibit no obvious difference in phenotypes in comparison with WT mice under normal circumstances, but exhibit an excessive response to hyperoxidative conditions, such as reperfusion injury. However, the arrhythmogenicity of the response to the hyperoxidative state in these mice is unclear. In this study, we used this heterozygous (HM-Sod2$^{+/-}$) mouse and a protocol designed to clarify the role of primary hyperoxidative stress derived from, and restricted to, the myocardium in the progression of electrical remodeling without apparent structural heart disease.

**Methods**

**Animals and Study Protocol**

We used H/M-Sod2$^{+/-}$ mice, produced by crossbreeding H/M-Sod2$^{+/-}$ mice with WT mice. HM-Sod2$^{+/-}$ mice were a gift from Dr. Shimizu, Tokyo Metropolitan Institute of Gerontology. H/M-Sod2$^{-/-}$ were produced by crossbreeding H/M-Sod2$^{+/-}$ mice with muscle creatine kinase (MCK)-Cre transgenic mice. H/M-Sod2$^{-/-}$ mice were a gift from Dr. Shimizu, Tokyo Metropolitan Institute of Gerontology. Sod2$^{-/-}$ mice were produced by crossbreeding H/M-Sod2$^{+/-}$ mice with muscle creatine kinase (MCK)-Cre transgenic mice using in vitro fertilization techniques. Genotyping was performed in the laboratory of Dr. Shimizu, Tokyo Metropolitan Institute of Gerontology. HB/M-Sod2$^{-/-}$ mice with WT mice. HM-Sod2$^{-/-}$ mice were a gift from Dr Shimizu, Tokyo Metropolitan Institute of Gerontology. H/M-Sod2$^{+/-}$ mice were produced by crossbreeding Sod2$^{-/-}$ mice with muscle creatine kinase (MCK)-Cre transgenic mice using in vitro fertilization techniques. Genotyping was performed by tail DNA polymerase chain reaction, as described previously (Figure S1). Nine-week-old H/M-Sod2$^{-/-}$ and WT mice were treated with BSO or saline for 7 days. The dose of BSO was 1.5 mmol/kg and it was intraperitoneally injected twice a day in the BSO-treated groups. In the control groups, saline of an equal volume was injected in the same manner. The mice were divided into 4 groups: heterozygous mice treated with BSO (H/M-Sod2$^{+/-}$+BSO, n=38), WT mice treated with BSO (WT+BSO, n=40), heterozygous mice treated with saline as a control (H/M-Sod2$^{+/-}$-control, n=38), and a WT control (n=40). On day 7, the parameters described below were evaluated and compared among the 4 groups. All studies were performed in accordance with the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (NIH Publication No. 85-23, revised 1996) and the Ethics Committee of Kitasato University School of Medicine.

**Histopathological Findings**

Body weights were measured every day. On day 7, the mice were sacrificed under anesthesia and whole hearts were excised for further analysis. The heart weight (HW) was measured. In randomly selected mice, the heart was transversely sliced and fixed in 10% formalin, embedded in paraffin, and stained with hematoxylin-eosin for histological evaluation.

**Physiological Evaluations**

The echocardiography was performed using ultrasonography (ProSound SSD-4000; ALOKA Co, Ltd, Tokyo, Japan) with a 4–14 MHz linear probe on day 7 of the study protocol. The heart was imaged in the 2-dimensional parasternal short-axis view, and a M-mode echocardiogram of the left ventricle was recorded at the level of the papillary muscle. Left ventricular diastolic and systolic dimensions (LVDd and LVDs), thickness of the interventricular septum (IVSth), thickness of the posterior wall (PWth) and left ventricular ejection fraction (LVEF) were obtained from the M-mode image.

On day 7, an electrophysiological evaluation was also performed in randomly selected mice (H/M-Sod2$^{+/-}$+BSO: n=8, WT+BSO: n=6, H/M-Sod2$^{+/-}$ control: n=8; and WT control: n=6). Under interperitoneal anesthesia with sodium pentobarbital (50 mg/kg for control groups, and 25 mg/kg for BSO-treated groups) and artificial ventilation, the heart was exposed through a median sternotomy. The depth of the anesthesia was controlled during the study by additional intravenous sodium pentobarbital so as not to exceed a heart rate of 400 beats/min. A pair of tungsten needle electrodes (φ 0.2 mm) was made to puncture all layers of the ventricle from the epicardium to the endocardium, and was used for the electrophysiological evaluation, as described previously. The ventricular effective refractory period (ERP) and the duration of monophasic action potential (MAPD) were evaluated. To evaluate the ERP, a single extra stimulus was delivered after 8 basic stimuli with a cycle length of 150 ms. The coupling interval of the extra stimulus was shortened in 2-ms steps until it reached ventricular refractoriness. The MAPD was determined as the interval between the onset of the MAP trace and the 20% (MAPD$_{20}$) and 90% (MAPD$_{90}$) repolarization times.

**Measurement of Total Glutathione Levels in Cardiac Tissue, and Serum Derivatives of Reactive Oxygen Metabolites (d-ROM)**

Cardiac tissues were homogenized in a phosphate-buffered saline solution, and interfering proteins were removed using 5% metaphosphoric acid. The total amount of glutathione (reduced and oxidized) in the myocardium was measured using the NDLSS Glutathione Assay (Northwest Life Science Specialties, LLC, Vancouver, WA, USA), and the data was corrected by the protein level in each sample. The serum levels of d-ROM were measured using the Free Radical Analytical System 4 (FRAS4; H&D srl, Parma, Italy).

**Expression of O$_2^-$ and H$_2$O$_2$ in the Myocardium**

The mitochondrial fraction of the myocardium was isolated using a Mitochondria Isolation KitTM (Sigma, St Louis, MO, USA). The purity of the mitochondrial fraction was verified by pre-incubation with their inhibitor, propylthiouracil, and Western blot analysis. H$_2$O$_2$ formation was measured using the chemiluminescent probe, MPEC (2-methyl-6-p-mercaptohexyl-phenylenediamidazoyprazinone; ATTO, Tokyo, Japan), by a luminometer (Lumat LB 9507; Berthold Technologies, Bad Wildbad, Germany). H$_2$O$_2$ generation was measured by using Amplex RedTM (Molecular Probes, Eugene, OR, USA). H$_2$O$_2$ formation was measured fluorometrically (excitation: 530 nm, emission: 590 nm) over 30 min at 37°C in a SpectraMax Gemini XS (Molecular Devices, Sunnyvale, CA, USA). Fluorescence units were converted to the standard curve for a known concentration of H$_2$O$_2$. The results are expressed as pmol H$_2$O$_2$/min/mg protein. To evaluate the in situ expression of ROS, fluorescent dihydroethidium (DHE, 10 μmol/L; Sigma) staining and 5- (and 6-) chloromethyl-2', 7'-dichlorodihydrofluorescein diacetate, acetyl ester (DCF-DA, 10 μmol/L; Molecular Probes, Eugene, OR, USA) staining were performed. The specificity of DHE and DCF-DA signals for O$_2^-$ and H$_2$O$_2$ detection was confirmed by pre-incubation with their inhibitor, polyethylene glycol-superoxide dismutase (PEG-SOD; 500 μU/ml, Sigma) and PEG-catalase (350 μU/ml, Sigma), respectively.

DHE or DCF-DA images were obtained with a laser-scanning confocal microscope (LMS710; Carl Zeiss MicroImaging Co,
identities were confirmed. Real-time RT-PCR was performed with pPCR MasterMix Plus for SYBR® Green I (Eurogentec s.a., Seraing, Liege, Belgium) and the CFD 3240 Chromo4™ Detection System (BioRad Lab, Inc, Richmond, CA, USA), as described previously.7,12 As the internal controls, the levels of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) were also evaluated.

**Western Blot Analysis**

Cardiac tissues were homogenized in ice-cold lysis buffer containing 50mmol/L Tris-HCl (pH 7.5), 1mmol/L EGTA, 150mmol/L NaCl, 0.25% SDC, 1mmol/L sodium orthovanadate, 1% Triton X-100, 2μg/ml aprotinin, 1mmol/L PMSF, and 5μg/ml leupeptin. The samples were used for Western blotting with antibodies for Sod2 (Stressgen, Victoria, Canada), Kv4.2/4.3 (Santa Cruz Biotechnology, Inc, Santa Cruz, CA, USA), ether-a-go-go-related gene (erg) 1/2/3 (Santa Cruz Ltd, Oberkochen, Germany). Fluorescence was quantified by ZEN 2008 image analysis software (Carl Zeiss MicroImaging Co, Ltd).

Cardiac Remodeling Through Primary Oxidative Stress

Biotechnology, Inc), K+ channel-interacting protein-2 (KChIP2) (ABGENT, San Diego, CA, USA), connexin 43 (Santa Cruz Biotechnology, Inc), and GAPDH (GeneTex ®, Inc, Irvine, CA, USA). After development with the ECL detection kit (Immobilon Western Chemiluminescent HRP Substrate; Millipore Corporation, Billerica, MA, USA), the density of each band in the digitized images was measured using the public domain NIH Image program. The expression levels were normalized to those of the WT control group.

Statistical Analysis
All values are expressed as the mean±SE. The basic comparative statistics were produced with a one-way ANOVA or unpaired t-test. The statistical analysis was performed with JMP 6 software for Windows (SAS Institute Inc, Cary, NC, USA). A P value of <0.05 was considered significant.

Results
Histopathological Findings
Table 1 shows changes in the body weights of mice along the time-course and HW on day 7. There were no differences in body weight among the 4 groups on days 0–5, but the H/M-Sod2+/−+BSO group weighed less than the control groups on days 6 and 7. HW showed no significant difference among the 4 groups. Figure 1 shows representative examples of hearts from the 4 groups. Isolated hearts did not show any differences in terms of macroscopic findings among the 4 groups. HE staining revealed no apparent fibrosis or degeneration of myocytes; however, partial misalignment of myocytes was observed in the H/M-Sod2+/−+BSO group.

Physiological Findings
In the echocardiography findings on day 7, there was no pathological finding in any mice. The echocardiographic data, that is, LVDd, LVDs, IVSth, PWth and LVEF, did not exhibit any differences among the 4 groups (Figure 2). Figure 3 shows the electrophysiological parameters on day 7. Representative MAP traces of the 4 groups are exhibited in Figure 3A. The MAP duration tended to be prolonged in H/M-Sod2+/−+BSO mice compared with the others. In the electrophysiological study, MAPd90 was markedly prolonged in both BSO-treated groups, that is, H/M-Sod2+/−+BSO and WT+BSO groups (Figure 3B; H/M-Sod2+/−+BSO vs. WT control, P=0.013; WT+BSO vs. WT control, P=0.021, respectively). In contrast, MAPd90 was prolonged only in the H/M-Sod2+/−+BSO group (Figure 3C; H/M-Sod2+/−+BSO vs. WT+BSO, P=0.139; H/M-Sod2+/−+BSO vs. H/M-Sod2+/− control, P=0.027; H/M-Sod2+/−+BSO vs. WT control, P=0.012, respectively). Similar to MAPd90, ERP was prolonged only in the H/M-
H₂O₂ produced in the myocardium. The BSO-treated groups exhibited markedly lower total glutathione levels than the other groups (H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P=0.009; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P=0.009; and WT+BSO vs. WT control, P=0.009, respectively). The levels of serum d-ROM were increased in the BSO-treated groups but the difference was significant only between H/M-Sod2<sup>−/−</sup>+BSO and the controls (H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P=0.007; H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P=0.021, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively).

**Evaluation of Oxidative Stress**

Table 2 and Figure 4 show the expression of antioxidants and the findings of oxidative stress in the present model. Table 2 shows the total amount of glutathione in the myocardium, serum d-ROM, and the amounts of mitochondrial O<sub>2</sub>− and H₂O₂ produced in the myocardium. The BSO-treated groups exhibited markedly lower total glutathione levels than the other groups (H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; and WT+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively). O<sub>2</sub>− levels in the H/M-Sod2<sup>−/−</sup>+BSO group (Figure 3D; H/M-Sod2<sup>−/−</sup>+BSO vs. WT+BSO, P<0.05; H/M-Sod2<sup>−/−</sup>+BSO vs. H/M-Sod2<sup>−/−</sup> control, P<0.05; and H/M-Sod2<sup>−/−</sup>+BSO vs. WT control, P<0.05, respectively).
Cardiac Remodeling Through Primary Oxidative Stress

els were increased in the H/M-Sod2+/− group in comparison with those in the WT+BSO group (P=0.029), and H2O2 levels were increased in the H/M-Sod2+/− group compared with those in the WT+BSO and WT control groups (P=0.006 and P=0.022, respectively). Figure 4A shows representative examples of bands from the Western blot analysis for Sod2 in cardiac tissue, and Figure 4B shows the mean densities of the bands of the Western blot for Sod2. Sod2 expression was downregulated in both H/M-Sod2+/− groups in comparison with that in the WT groups (n=3 in each group). *P<0.05 vs. WT control. †P<0.05 vs. WT+BSO. (C) Representative examples of DHE and DCF-DA staining. DHE was clearly stained in the nuclei of the myocardial cells in the H/M-Sod2+/−+BSO group, and was negated by pre-incubation with PEG-SOD. DCF-DA was stained in the cytoplasm of the myocardial cells in the BSO-treated groups. The fluorescence of DCF-DA was reduced by pre-incubation with PEG-catalase. (D) Mean fluorescence intensity of DHE staining. The fluorescence intensity of DHE staining was higher in the H/M-Sod2+/−+BSO group than in the WT control group (n=3 in each group). *P<0.05 vs. WT control. (E) Mean fluorescence intensity of DCF-DA staining. The fluorescence intensity of DCF-DA staining was higher in the BSO-treated groups than in the H/M-Sod2+/− control group (n=3 in each group). ‡P<0.05 vs. H/M-Sod2+/− control. See text for discussion. H/M-Sod2+/−, heterozygous heart/muscle-specific manganese superoxide dismutase-deficient mice; Sod2, superoxide dismutase 2; BSO, L-buthionine-sulfoximine; WT, wild type; DHE, fluorescent dihydroethydium; DCF-DA, 5-(and 6-)chloromethyl-2′, 7′-dichlorodihydrofluorescein diacetate, acetyl ester; PEG-SOD, polyethylene glycol-superoxide dismutase.

Figure 5. Western blot analysis of downregulated molecules in hyperoxidative mice. This figure shows the results of a Western blot analysis of potassium channels, KChIP2 and connexin 43. (A) Representative examples of each band in the Western blot analysis. (B) Mean densities of the bands for Kv4.2. The expression of Kv4.2 was downregulated in both BSO-treated groups in comparison with the WT control. *P<0.05 vs. WT control. (C) Mean densities of the bands for KChIP2. The expression of KChIP2 was downregulated only in the H/M-Sod2+/–+BSO group in comparison with the WT control. *P<0.05 vs. WT control. See text for discussion. KChIP2, K⁺ channel-interacting protein-2; WT, wild type; BSO, L-buthionine-sulfoximine; H/M-Sod2+/–, heterozygous heart/muscle-specific manganese superoxide dismutase-deficient mice.
Changes in Expression Levels of Cardiac Remodeling-Related Molecules

Table 3 lists the results of the RT-PCR analyses. Significant reductions were observed in the expression levels of Kv4.2, Kv4.3, erg, KChIP2 and connxin 43 in the H/M-Sod2+/–+BSO group in comparison with the controls or the WT+BSO group. The mRNA expression of Kv4.2 was downregulated in both the H/M-Sod2+/–+BSO and WT+BSO groups compared with the controls. In contrast, Kv4.3, erg, KChIP2, and connxin 43 levels were reduced only in the H/M-Sod2+/–+BSO group. In addition, the expression level of Kv2.1 was upregulated in the H/M-Sod2+/– control compared with that in the WT control. There was no difference among the 4 groups in the mRNA expression of Kv1.5, Kir2.1, Kir2.2, L-type Ca2+ channel (L-Ca2+), sodium channel, voltage-gated, type V, alpha subunit (SCN5A) and GAPDH.

Figure 5 shows the results of Western blot analyses of the molecules described above. Figure 5A shows representative bands, and Figures 5B and 5C show the mean densities of the bands for Kv4.2 and KChIP2, respectively. The expression of Kv4.2 was downregulated in both BSO-treated groups in comparison with the WT controls. The expression of KChIP2 was downregulated only in the H/M-Sod2+/–+BSO group. In contrast, there were no significant differences in the levels of Kv4.3, erg-1, and connxin 43 among the 4 groups.

Discussion

In the present study, we evaluated the electrical remodeling in H/M-Sod2+/– mice treated with BSO, which produces cardiomyocyte-derived mitochondrial superoxide in the cardiac tissue, and made several interesting findings. First, the heart of H/M-Sod2+/–+BSO mice exhibited decreases in Sod2 and total glutathione, and this resulted in the hyper-production of mitochondrial O2– and H2O2. Second, H/M-Sod2+/–+BSO mice did not show any mechano-functional changes in echocardiography, but exhibited a prolongation of MAPD and ERP in comparison with the controls, which can be considered as electrical remodeling promoted by primary oxidative stress. Finally, the expression of Kv4.2 was downregulated in both BSO-treated groups, but the expression of KChIP2 was downregulated only in the H/M-Sod2+/–+BSO group.

BSO-Treated H/M-Sod2+/– Mice, a Model of Cardiomyocyte-Derived Primary Hyper Oxidative Stress

We previously reported that systemic oxidative stress caused electrical remodeling and an increase in arrhythmogenicity in BSO-treated glutathione-depleted systemic oxidative stress rats. However, in that model, the primary and secondary effects of oxidative stress could not be separated because a hyperoxidative state was induced in all of the systemic organs due to the suppressive effect of BSO on the γ-glutamylcyesteine synthetase. Therefore, in this study, we designed a model with presenting hyper-production of ROS originating from mitochondria of cardiomyocytes using H/M-Sod2+/– mice to evaluate the effect of cardiomyocyte-derived primary oxidative stress on the cardiac tissue.

O2– is generated in compensation for the production of adenosine triphosphate (ATP) in mitochondria and metabolized by Sod2 to produce H2O2, which is consequently converted to H2O by the actions of the oxidative stress metabolizing system including the glutathione system. Therefore, a dysfunction of Sod2 will induce hyper-production of ROS originating from mitochondria. The H/M-Sod2+/– mouse has been reported to exhibit heart failure with a dilated cardiomyopathy-like condition due to a congenital hyperoxidative state in its cardiac tissue. In contrast, the H/M-Sod2+/– mouse, which was used in this study, does not show any pathological findings in cardiac tissue and HW unless it was suffering from some pathological condition, although it might exhibit some structural changes in later months. In this study, we added a relatively small amount of BSO as pathological stress to H/M-Sod2+/– mice and succeeded in inducing a cardiomyocyte-derived primary hyperoxidative state in the cardiac tissue. Sod2 expression was decreased by half in H/M-Sod2+/– mice, as shown in Figures 4A and 4B, and total glutathione levels were suppressed by the BSO treatment in both WT and H/M-Sod2+/– mice, as shown in Table 2. Interestingly, the BSO treatment promoted hyper-production of both mitochondrial and cytoplasmic ROS (O2– and H2O2) in the hearts of H/M-Sod2+/– mice, whereas only cytoplasmic H2O2 formation was induced in WT mice (Table 2, Figures 4C–E). The serum d-ROM level was considered to be increased in H/M-Sod2+/–+BSO mice as the result of such changes in ROS production. Therefore, this can be a novel model of primary and acquired hyperoxidative stress restricted to cardiac or skeletal muscles, which can be induced at any age by BSO treatment.

Electrical Remodeling in Cardiomyocyte-Derived Primary Hyper Oxidative Stress

Although oxidative stress is considered to be involved in functional or structural cardiovascular remodeling in various diseased states, its direct role is unclear. In our report using an experimental model of autoimmune myocarditis in rats, we have emphasized the role of oxidative stress in the electrical and structural remodeling in the acute phase of myocarditis, but the effect of oxidative stress could not be separated from various stimulations during immune and inflammatory processes.

Our previous study using BSO-treated glutathione-depleted rats was the first to evaluate the effect of primary oxidative stress on cardiac remodeling in vivo, and revealed no structural change but there were electrophysiological changes, that is, ERP shortening and MAPD prolongation, and the downregulated expression of erg and sarcoendoplasmic reticulum Ca2+-ATPase 2 (SERCA2). In contrast, in the present study, BSO-treated H/M-Sod2+/– mice exhibited ERP prolongation, MAPD prolongation and the downregulated expression of Kv4.2 and KChIP2 in comparison with the WT control, but no significant difference was observed in the expression of erg, at least not at the protein level. The precise reason for these differences is unclear, but it might relate to the difference in the expression pattern of ROS as well as the difference in animal species. As discussed in the previous paragraph, the results in the former model might have been primary changes but were caused by systemic oxidative stress, while those in the latter model are considered to have been induced by primary hyper-Ros formation restricted to the cardiac and skeletal muscles. From the results of these 2 studies, the initial effect of primary oxidative stress on cardiomyocytes could perhaps be summarized as ERP and MAPD prolongation. Although WT+BSO mice exhibited some changes in electrophysiological properties, the degree of change was much smaller than in H/M-Sod2+/–+BSO mice. This can probably be explained by the difference in the intensity of the oxidative stress in the cardiac tissue, because mitochondrial O2– and H2O2 production should be more enhanced in cardiomyocytes in H/M-Sod2+/–+BSO mice, and the effect of systemic oxidative stress on the cardiac tissue would be limited in WT+BSO mice. Although the amount of BSO used in this study was relatively small, one
would expect that such treatment would also induce myocardial hyper-production of ROS. In accordance with the findings of DCF-DA staining, hyper-production of H$_2$O$_2$ might occur even in the cytoplasm of the myocardial cells of WT+BSO mice. However, in the measurement of O$_2^-$ or H$_2$O$_2$ production, a hyper-ROS state was not observed, at least in the mitochondrial fraction of the myocardium, so it was considered that a myocardial mitochondria-derived hyper-ROS state was not induced in WT+BSO mice. Because prolongation of ERP and MAPD$_{90}$ was observed only in the H/M-Sod2$^{+/+}$+BSO mice, primary hyper-ROS production was considered to induce electrical remodeling independently of the structural remodeling or cellular dysfunction of the myocardium.

**Mechanism Responsible for the Changes in Electrophysiological Properties**

Although the direction of change in ERP and MAPD was opposite in the BSO-treated glutathione-depleted rats, both ERP and MAPD were prolonged in the H/M-Sod2$^{+/+}$+BSO mice in the present study. The prolongation of ERP coincides with the marked prolongation of MAPD$_{90}$ and the prolongation of MAPD$_{90}$ is reflected in the change in the shape of the MAP trace (Figure 3A). These MAPD prolongations can be explained by decreases in outward potassium currents, and significant reductions were observed in Kv4.2 and KChIP2 levels in the present study. KChIP2 is known to regulate the expression and function of Kv4.2 and Kv4.3, and its downregulation will result in an enhanced decay of I$_{Ks}$, a prolongation action potential duration, and an increase in arrhythmogenicity. These results are compatible with several reports of the downregulation of I$_{Ks}$ or I$_{Ks}$-related molecules under conditions with hyperoxidative stress. Because I$_{Ks}$ is a major regulator of action potential duration in rodents, it has been reported that the downregulation of I$_{Ks}$ caused prolongation of APD$_{90}$ or APD$_{90}$ in a dominant-negative Kv4.2 channel mouse model. It is supposed that the prolongation of MAPD$_{90}$ can also be explained by changes in the expression of I$_{Ks}$-related molecules. It was reported that intracellular Ca$^{2+}$ load, increase of calcineurin, or oxidation of CaMKII causes activation or overexpression of CaMKII. These reactions produce the downregulation of KChIP2 and Kv4.2, decrease of I$_{Ks}$, and prolongation of APD. It is suggested that these mechanisms affected the downregulation of KChIP2 and Kv4.2 in the present model.

In addition, Kv1.5 and Kv2.1 form the I$_{Ks}$ slow current and are also related to the later part of the repolarization process in mouse myocardium. MAPD$_{90}$ was prolonged only in H/M-Sod2$^{+/+}$+BSO mice in the present study, although there were no significant differences in Kv1.5 and Kv2.1 expression in H/M-Sod2$^{+/+}$+BSO mice, so it is supposed that the prolongation of MAPD$_{90}$ was not caused by changes of Kv1.5 and Kv2.1. Similarly, Kir2.1 and Kir2.2, which form the I$_{Ks}$ current, and L-Ca$^{2+}$ did not show significant differences among the 4 groups, which suggested that these channels were not related to the prolongation of MAPD. We produced a unique model of primary and acquired hyper-oxidative stress restricted to cardiac or skeletal muscles by using H/M-Sod2$^{+/+}$+BSO mice. The cardiomyocyte-derived mitochondrial superoxide caused electrical remodeling, characterized by a prolongation of MAPD and ERP. The downregulation of Kv4.2 and KChIP2 expression might be involved as a mechanism of cardiac remodeling in this model of primary oxidative stress.
