CLOSURES OF K-ORBITS IN THE FLAG VARIETY FOR $U(p, q)$

WILLIAM M. MCGOVERN

ABSTRACT. We classify the $GL_p \times GL_q$-orbits in the flag variety for $GL_{p+q}$ with rationally smooth closure, showing that they are all either already closed or are pullbacks from orbits with smooth closure in a partial flag variety.

1. Introduction

Let $G$ be a complex reductive group with Borel subgroup $B$. The question of which Schubert varieties in the flag variety $G/B$ are smooth has received a great deal of attention, particularly in recent years [BilLak00, BilPos05]. Less well studied, but very important for representation theory, are the closures of orbits in $G/B$ under the action of the fixed point subgroup $K := G^\theta$ of $G$, where $\theta$ is an involutive automorphism of $G$ [LasVog83]. Such orbit closures have been called symmetric varieties by Springer and are studied by him in [Spr92]. In this paper we use his techniques to decide which symmetric varieties are smooth in the special case $G = GL(p+q, \mathbb{C}), K = GL(p, \mathbb{C}) \times GL(q, \mathbb{C})$. We will give a pattern avoidance criterion for rational smoothness, along the lines of the well-known one for rational smoothness of Schubert varieties in type $A$. We will also show that all rationally smooth symmetric varieties in this case are either closed orbits or pullbacks of smooth varieties in partial flag varieties and so in particular are smooth. In a joint paper with Peter Trapa, we extend the characterization of the rationally smooth symmetric varieties to the flag varieties for the real groups $Sp(p, q)$ and $SO^*(2n)$ [McGT08].

I would like to thank Peter Trapa for many very helpful conversations and Leticia Barchini for pointing out an error in an earlier version of this paper.

2. Preliminaries

Now let $G = GL(n, \mathbb{C})$, where $n = p + q$, and take $\theta$ to be conjugation by a diagonal matrix on $G$ with $p$ eigenvalues 1 and $q$ eigenvalues $-1$, so that $K = G^\theta = GL(p, \mathbb{C}) \times GL(q, \mathbb{C})$. This group may also be viewed as the complexification of the maximal compact subgroup $U(p) \times U(q)$ of the real form $U(p, q)$ of $G$. Let $B$ be the subgroup of upper triangular matrices in $G$. As is well known, the quotient $G/B$ may be identified with the set of complete flags $V_0 \subset V_1 \subset \cdots \subset V_n$ in $\mathbb{C}^n$. Let $P$ be the span of the first $p$ vectors of the standard basis of $\mathbb{C}^n$. Recall that $K$-orbits in $G/B$ are parametrized by clans, which are sequences $\gamma = (c_1, \ldots, c_n)$ of $n$ symbols $c_i$, each either $+$ or $-$ or a natural number, such that every natural number occurs either exactly twice in $\gamma$ or not at all [MatOsh88, Yam97]. In this parametrization the orbit corresponding to $(c_1, \ldots, c_n)$ consists of flags $V_0 \subset \cdots \subset V_n$ for which the dimension of $V_i \cap P$ equals the number of $+$ signs and pairs of equal numbers among $c_1, \ldots, c_i$, for all $i$ between 1 and $n$. In particular, the number of $+$ signs and pairs of equal numbers in the entire clan must be exactly $p$. We identify two clans...
if they have the same signs in the same positions and pairs of equal numbers in the same positions (so that for example $(1, +, 1, -)$ is identified with $(2, +, 2, -)$, but not with $(1, +, -)$). We say that the clan $\gamma = (c_1, \ldots, c_n)$ includes the pattern $(d_1, \ldots, d_m)$ if there are indices $i_1 < \cdots < i_m$ such that the (possibly shorter) clans $(c_{i_1}, \ldots, c_{i_m})$ and $(d_1, \ldots, d_m)$ are identified. We say that $\gamma$ avoids $(d_1, \ldots, d_m)$ if it does not include it. If $Q$ is a parabolic subgroup of $G$, corresponding to an arrangement of the $n$ coordinates into blocks of consecutive coordinates (each block having only one coordinate if $Q = B$), then the quotient $G/Q$ may be identified with the set of partial flags $V_0 \subset \cdots \subset V_m$ in $\mathbb{C}^n$ such that the dimension of $V_i$ is the sum of the sizes of the first $i$ blocks of coordinates. Then $K$-orbits in $G/Q$ are likewise parametrized by clans, except that we identify two clans whenever corresponding blocks of coordinates have the same signatures (number of + signs plus pairs of equal numbers, and similarly for − signs) and pairs of blocks in one clan have the same number of numbers in common as the corresponding pairs of blocks in the other clan. For example, if $p = q = 3$ and $Q$ corresponds to the coordinate arrangement $(1), (2, 3, 4, 5), (6)$, or to the middle three roots in the Dynkin diagram of $G$, then the clans $(1, +, 2, -, 2, 1)$ and $(1, 2, 3, 4, 5, 6, 7, 8)$ then the clans $(1, +, 1, -)$ and $(1, 2, 3, 4)$ are identified, and $\gamma$ avoids $(d_1, \ldots, d_m)$ if it does not include it. If $Q$ is the fixed points under an involution $\theta$.

We conclude this section by recalling and slightly generalizing the well-known derived functor module construction on the level of $K$-orbits. For this purpose let $G$ be any complex reductive group and $K$ its fixed points under an involution $\theta$. Let $Q$
be any $\theta$-stable parabolic subgroup of $G$, containing the $\theta$-stable Borel subgroup $B$. If $q$ is the Lie algebra of $Q$, then the orbit $K \cdot q$ identifies with a closed orbit in the partial flag variety $G/Q$ [RiSpr90, 2.5]. Its preimage $\pi^{-1}(K \cdot q)$ in $G/B$ under the natural projection $\pi: G/B \to G/Q$ is the support of a derived functor module; we call the open orbit in this preimage a derived functor orbit [Lya05 §1]. Its closure fibers smoothly via $\pi$ over $K \cdot q$ with fiber the flag variety $Q/B$ of $Q$ (which may be identified with the flag variety of any Levi factor of $Q$), so it is smooth. More generally, let $O_Q$ be any $K$-orbit in $G/Q$ with smooth closure $O_Q$. The preimage $\pi^{-1}(O_Q)$ fibers smoothly over $O_Q$ with fiber $Q/B$, so is again smooth. We also call the open orbit $O$ in this preimage a derived functor orbit; to avoid trivialities, we assume that $Q \neq B$ in the more general setting, unless $O_B$ is already closed in $G/B$. (Thus closed orbits in $G/B$ are also called derived functor orbits.)

3. Main result

Now we can characterize the $K$-orbits with rationally smooth closure.

**Theorem.** If the clan $\gamma = (c_1, \ldots, c_n)$ includes one of the patterns $(1, +, -, 1)$, $(1, -, +, 1)$, $(1, -2, 2, 1)$, $(1, +, -2, 2, 1)$, $(1, 2, 2, 1)$, or $(1, 2, 2, -1)$, then the orbit $O_{\gamma}$ does not have rationally smooth closure. Otherwise $O_{\gamma}$ is a derived functor orbit, so that its closure is smooth. In particular, Springer’s necessary condition for rational smoothness in [Spr92] is sufficient in this setting and smoothness and rational smoothness are equivalent.

**Proof.** Suppose first that $\gamma$ includes one of the above patterns. If this pattern has just two equal numbers, replace them by $-$ and $+$, in that order; if it includes two such pairs, replace the four numbers by $-, +, -, +$, in that order. In all seven cases, continue by replacing every pair $a, \ldots, a$ of equal numbers in $\gamma$ by $+, \ldots, -$. We obtain a clan corresponding to a closed orbit $O$ below $O_{\gamma}$ in the partial order. Now Springer has defined an action of the noncompact root reflections in the Weyl group $S_n$ on the closed orbits, sending each such orbit to a higher orbit whose clan has exactly two numbers; more precisely, any two opposite signs in the clan of the closed orbit may be replaced by a pair of equal numbers [Spr92, 3.1,4.1]. One easily checks that more than $\dim O_{\gamma} - d_{p,q}$ of these reflections send $O$ to an orbit lying between it and $O_{\gamma}$, whence $O_{\gamma}$ is not rationally smooth, as claimed [Spr92, 3.2,3.3].

Now suppose that $\gamma$ avoids the above patterns. Then the intervals $[s, t]$ of indices $s, t$ with $c_s = c_t \in \mathbb{N}$ are such that any two of them are one contained in the other or disjoint. All signs lying between any pair of equal numbers in $\gamma$ are the same. Moreover, if a sign lies between a pair of equal numbers, then it also lies between every pair of equal numbers enclosed by the first pair. If $\gamma$ has a sign not lying between a pair of equal numbers, let $Q$ be the parabolic subgroup of $G$ corresponding to the simple roots not involving the coordinate of the sign. Deleting this sign from $\gamma$, we obtain one or two clans, one consisting of the coordinates of $\gamma$ to the left of this sign, the other of the coordinates of $\gamma$ to the right of it. By induction on the number of coordinates of $\gamma$, we may assume that the orbits corresponding to these clans have smooth closure. One computes that the image of $O_{\gamma}$ under $\pi$ identifies with the closed orbit $K \cdot q$ in $G/Q$, with the same clan $\gamma$, and that $O_{\gamma}$ fibers smoothly over this orbit via the projection $\pi: G/B \to G/Q$ with smooth fiber parametrized by the clan $\gamma$ with the sign deleted. Hence $O_{\gamma}$ is smooth, as desired. If $\gamma$ consists of at least two blocks of coordinates, each flanked by pairs of equal
numbers not lying between any other pair of equal numbers, with no signs lying between the blocks, then a similar argument shows that \( O_\gamma \) has smooth closure, taking \( Q \) to be the parabolic subgroup corresponding to the simple roots whose coordinates lie in the same block. Otherwise the first and last coordinates of \( \gamma \) are a pair of equal numbers. Taking \( Q \) to be the parabolic subgroup of \( G \) corresponding to the remaining coordinates, we now find that the image of \( \overline{O_\gamma} \) under \( \pi \) is the full flag variety \( G/Q \), and the restriction of \( \pi \) to this orbit closure has smooth fibers, parametrized by the clan consisting of these coordinates of \( \gamma \). Hence in all cases this orbit closure is smooth. If \( O_\gamma \) is not already closed, let \( c_i = c_j = a \) be a pair of equal numbers in \( \gamma \) with no numbers between them. Let \( Q \) be the parabolic subgroup of \( G \) corresponding to the coordinates weakly between \( i \) and \( j \). Then the image of \( \overline{O_\gamma} \) under \( \pi \) is smooth in \( G/Q \) and \( O_\gamma \) is the derived functor orbit obtained from this image, as desired. □

In future work we hope to find similar pattern avoidance criteria for rational smoothness of \( K \)-orbit closures in the flag varieties of other classical groups. There are two nonsmooth orbit closures for \( GL(4, \mathbb{R}) \), none for \( SU^*(4) \), and one for \( SU^*(6) \).
