FRAME MULTIPLICATION THEORY AND A VECTOR-VALUED DFT AND AMBIGUITY FUNCTION

TRAVIS D. ANDREWS, JOHN J. BENEDETTO, AND JEFFREY J. DONATELLI

ABSTRACT. Vector-valued discrete Fourier transforms (DFTs) and ambiguity functions are defined. The motivation for the definitions is to provide realistic modeling of multi-sensor environments in which a useful time-frequency analysis is essential. The definition of the DFT requires associated uncertainty principle inequalities. The definition of the ambiguity function requires a component that leads to formulating a mathematical theory in which two essential algebraic operations can be made compatible in a natural way. The theory is referred to as frame multiplication theory. These definitions, inequalities, and theory are interdependent, and they are the content of the paper with the centerpiece being frame multiplication theory.

The technology underlying frame multiplication theory is the theory of frames, short time Fourier transforms (STFTs), and the representation theory of finite groups. The main results have the following form: frame multiplication exists if and only if the finite frames that arise in the theory are of a certain type, e.g., harmonic frames, or, more generally, group frames.

In light of the complexities and the importance of the modeling of time-varying and dynamical systems in the context of effectively analyzing vector-valued multi-sensor environments, the theory of vector-valued DFTs and ambiguity functions must not only be mathematically meaningful, but it must have constructive implementable algorithms, and be computationally viable. This paper presents our vision for resolving these issues, in terms of a significant mathematical theory, and based on the goal of formulating and developing a useful vector-valued theory.

1. Introduction

This is a research survey in the mold of this journal’s intent from the very beginning to publish some papers of this type, see [110]. As such, it provides research results embedded in a broad program of future work with tentacles reaching into diverse topics.

1.1. Background. Our background for this work was based in the following program.

Date: November 4, 2018.
2010 Mathematics Subject Classification. 42, 42C15, 43, 46, 46J, 65T50.
Key words and phrases. Vector-valued DFT and ambiguity function, frame theory, harmonic and group frame, uncertainty principle, quaternions.

The first named author gratefully acknowledges the support of the Norbert Wiener Center. The second named author gratefully acknowledges the support of DTRA Grant 1-13-1-0015 and ARO Grants W911NF-15-1-0112 and 17-1-0014. The third named author gratefully acknowledges the support of the Norbert Wiener Center. We all acknowledge the definitive frame theoretic comments of the anonymous referee. We truly appreciate the magisterial suggestions with regard to scholarship of Professor Hans Feichtinger and the world class expertise on finite frames of Professor Kasso Okoudjou. Finally, we are thankful for the critical technical suggestions of Raymond Schram of the University of Maryland. All suggestions have been incorporated, except that we persist in using the notation, $\mathbb{Z}/N\mathbb{Z}$, instead of $\mathbb{Z}_N$, with the advice of our number theoretic colleagues.
Originally, our problem was to construct libraries of phase-coded waveforms $v : \mathbb{R} \rightarrow \mathbb{C}$, parameterized by design variables, for use in communications and radar. A goal was to achieve diverse narrow-band ambiguity function behavior of $v$ by defining new classes of discrete quadratic phase and number theoretic perfect autocorrelation sequences $u : \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}$ with which to define $v$ and having optimal autocorrelation behavior in a way to be defined.

Then, a realistic more general problem was to construct vector-valued waveforms $v$ in terms of vector-valued sequences $u : \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}^d$ having this optimal autocorrelation behavior. Such sequences are relevant in light of vector sensor capabilities and modeling, e.g., see [88,111].

In fact, we shall define periodic vector-valued discrete Fourier transforms (DFTs) and narrow-band ambiguity functions. Early-on we understood that the accompanying theory could not just be a matter of using bold-faced letters to recount existing theory, an image used by Joel Tropp for another multi-dimensional situation. Two of us recorded our initial results on the subject at an invited talk at Asilomar (2008), [16], but we did not pursue it then, because there was the fundamental one-dimensional problem, mentioned above in the first bullet, that had to be resolved. Since then, we have made appropriate progress on this one-dimensional problem, see [10–13,15,23].

1.2. Goals and short time Fourier transform (STFT) theme. In 1953, P. M. Woodward [129,130] defined the narrow-band radar ambiguity function. The narrow-band ambiguity function is a two-dimensional function of delay $t$ and Doppler frequency $\gamma$ that measures the correlation between a waveform $w$ and its Doppler distorted version. The information given by the narrow-band ambiguity function is important for practical purposes in radar. In fact, the waveform design problem is to construct waveforms having “good” ambiguity function behavior in the sense of being designed to solve real problems.

Since we are only dealing with narrow-band ambiguity functions, we shall suppress the words “narrow-band” for the remainder.

**Definition 1.1** (Ambiguity function). a. The ambiguity function $A(v)$ of $v \in L^2(\mathbb{R})$ is

\[
A(v)(t, \gamma) = \int_{\mathbb{R}} v(s + t)\overline{v(s)}e^{-2\pi is\gamma} ds = e^{\pi it\gamma} \int_{\mathbb{R}} \overline{v\left(\frac{s + t}{2}\right)} v\left(\frac{s - t}{2}\right)e^{-2\pi is\gamma} ds,
\]

for $(t, \gamma) \in \mathbb{R}^2$.

b. We shall only be interested in the discrete version of (1). For an $N$-periodic function $u : \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}$ the discrete periodic ambiguity function is

\[
A_p(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} u(m + k)\overline{u(k)}e^{-2\pi i mn/N},
\]

for $(m, n) \in \mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/N\mathbb{Z}$. 

c. If \( v, w \in L^2(\mathbb{R}) \), the cross-ambiguity function \( A(v, w) \) of \( v \) and \( w \) is
\[
A(v, w)(t, \gamma) = \int_{\mathbb{R}} v(s + t)\overline{w(s)}e^{-2\pi is\gamma} \, ds
\]
\[
e^{2\pi it\gamma} \int_{\mathbb{R}} v(s)\overline{w(s - t)}e^{-2\pi is\gamma} \, ds.
\]
(3)

Evidently, \( A(v) = A(v, v) \), so that the ambiguity function is a special case of the cross-ambiguity function.

\[ d. \] The short-time Fourier transform (STFT) of \( v \) with respect to a window function \( w \in L^2(\mathbb{R}) \setminus \{0\} \) is
\[
V_w(v)(t, \gamma) = \int_{\mathbb{R}} v(s)\overline{w(s - t)}e^{-2\pi is\gamma} \, ds
\]
for \((t, \gamma) \in \mathbb{R}^2\), see [63] for a definitive mathematical treatment. Thus, we think of the window \( w \) as centered at \( t \), and we have
\[
A(v, w)(t, \gamma) = e^{2\pi it\gamma} V_w(v)(t, \gamma).
\]
(5)

\[ e. \] \( A(v, w) \) and \( V_w(v) \) can clearly be defined for functions \( v, w \) on \( \mathbb{R}^d \) and for other function spaces besides \( L^2(\mathbb{R}^d) \). The quantity \(|V_w(v)|\) is the spectrogram of \( v \), that is so important in power spectrum analysis. For this and related applicability, see, e.g., [26, 30, 34, 50, 81, 92, 96, 99, 119, 128].

Our goals are the following.

- Ultimately, we shall establish the theory of vector-valued ambiguity functions of vector-valued functions \( v \) on \( \mathbb{R}^d \) in terms of their discrete periodic counterparts on \( \mathbb{Z}/N\mathbb{Z} \), see Example 3.12 for generalization beyond \( \mathbb{R}^d \).
- To this end, in this paper, we define the vector-valued DFT and the discrete periodic vector-valued ambiguity functions on \( \mathbb{Z}/N\mathbb{Z} \) in a natural way.

The STFT is the guide and the theory of frames, especially the theory of DFT, harmonic, and group frames, is the framework (sic) to formulate these goals. The underlying technology that allows us to obtain these goals is frame multiplication theory. Implications of the role of group frames are found in Example 6.11

1.3. Outline. We begin with an exposition on the theory of frames (Section 2). Frames are essential for our results, and in applications the material related to our results is often not conceived or formulated in terms of frames.

The vector-valued discrete Fourier transform (DFT) is developed in Subsection 3.1. The remaining two subsections of Section 3 conclude with a comparison of relations between Subsection 3.1 and apparently different implications from the Gelfand theory. Subsection 3.1 is required in our vector-valued ambiguity function theory.

Section 4 establishes the basic role of the STFT in achieving the goals listed in Subsection 1.2. In the process, we formulate our idea leading to the notion of frame multiplication, that is used to define the vector-valued ambiguity function. In Section 4 we also give two diverse examples. The first is for DFT frames (Subsection 4.2), that we present in an Abelian setting. The second is for cross-product frames (Subsection 4.4), that is fundamentally non-Abelian and non-group with regard to structure, and that is motivated by the recent applicability of quaternions, e.g., [85]. Subsection 4.3 relates the examples of Subsections 4.2 and 4.4, and formally motivates the theory of frame multiplication presented in Section 5.
In Section 6 we define the harmonic and group frames that are the basis for our Abelian group frame multiplication results of Section 7. Although we present the results in the setting of finite Abelian groups and frames for the Hilbert space $\mathbb{C}^d$, many of them can be generalized; and, in fact, some are more easily formulated and proved in the general setting. As such, some of the theory in these sections is given in infinite and/or non-Abelian terms. The major results are stated and proved in Subsection 7.2. They characterize the existence of frame multiplication in term of harmonic and group frames.

Section 8.2 is devoted to the uncertainty principle in the context of our vector-valued DFT theory.

We close with Appendix 9. Some of this material is used explicitly in Sections 6 and 7, and some provides a theoretical umbrella to cover the theory herein and the transition to the non-Abelian case beginning with [3].

Remark 1.2. The forthcoming non-Abelian theory is due to Travis Andrews [3]. In fact, if $(G, \cdot)$ is a finite group with representation $\rho: G \to GL(\mathbb{C}^d)$, then we can show that there is a frame $\{x_n\}_{n \in G}$ and bilinear multiplication, $\ast: \mathbb{C}^d \times \mathbb{C}^d \to \mathbb{C}^d$, such that $x_m \ast x_n = x_{m \cdot n}$.

Further, we are extending the theory to tight frames for $\mathbb{C}^d$ and finite rings $G$, so that there are meaningful generalizations of the vector-valued $A_p^d(u)$ theory in the formal but motivated settings of Equations (20) and (21).

It remains to establish the theory in infinite dimensional Hilbert spaces and associated infinite locally compact groups and rings as well as tantalizing non-group cases, see, e.g., our cross product example in Subsection 4.4 and its relationship to quaternion groups.

2. Frames

2.1. Definitions and properties. Frames are a generalization of orthonormal bases where we relax Parseval’s identity to allow for overcompleteness. Frames were first introduced in 1952 by Duffin and Schaeffer [44] and the theory has developed extensively since the 1980s. e.g., see [8, 25, 33, 35, 39, 125]. (In fact, Paley and Wiener gave the technical definition of a frame in [95], but they only developed the completeness properties.)

Definition 2.1 (Frame). a. Let $H$ be a separable Hilbert space over the field $\mathbb{F}$, where $\mathbb{F} = \mathbb{R}$ or $\mathbb{F} = \mathbb{C}$. A finite or countably infinite sequence, $X = \{x_j\}_{j \in J}$, of elements of $H$ is a frame for $H$ if

$$\exists A, B > 0 \text{ such that } \forall x \in H, \quad A \|x\|^2 \leq \sum_{j \in J} |\langle x, x_j \rangle|^2 \leq B \|x\|^2. \tag{6}$$

The optimal constants, viz., the supremum over all such $A$ and infimum over all such $B$, are called the lower and upper frame bounds respectively. When we refer to frame bounds $A$ and $B$, we shall mean these optimal constants.

b. A frame $X$ for $H$ is a tight frame if $A = B$. If a tight frame has the further property that $A = B = 1$, then the frame is a Parseval frame for $H$.

c. A frame $X$ for $H$ is equal-norm if each of the elements of $X$ has the same norm. Further, a frame $X$ for $H = \mathbb{C}^d$ is a unit norm tight frame (UNTF) if each of the elements of $X$ has norm 1. If $H = \mathbb{C}^d$ and $X$ is an UNTF for $H$, then $X$ is a finite unit norm tight frame (FUNTF).

d. A sequence of elements of $H$ satisfying an upper frame bound, such as $B \|x\|^2$ in (6), is a Bessel sequence.
Remark 2.2. The series in (6) is an absolutely convergent series of positive numbers; and so, any reordering of the sequence of frame elements or reindexing by another set of the same cardinality will remain a frame. We allow for repetitions of vectors in a frame so that, strictly speaking, the set of vectors, that we also call $X$, is a multi-set. We shall index frames by an arbitrary sequence such as $J$ in the definition, or by specific sequences such as the set $\mathbb{N}$ of positive integers or the set $\mathbb{Z}^d, d \geq 2$, of multi-integers when it is natural to do so.

Let $X = \{x_j\}_{j \in J}$ be a frame for $H$. We define the following operators associated with every frame. The analysis operator $L : H \to \ell^2(J)$ is defined by

$$\forall x \in H, \quad Lx = \{\langle x, x_j \rangle\}_{j \in J}. $$

Inequality (6) ensures that the operator norm of $L$ is bounded, i.e., $\|L\|_{op} \leq \sqrt{B}$. The adjoint of the analysis operator is the synthesis operator $L^* : \ell^2(J) \to H$, defined by

$$\forall a \in \ell^2(J), \quad L^*a = \sum_{j \in J} a_j x_j. $$

From Hilbert space theory, we know that any bounded linear operator $T : H \to H$ satisfies $\|T\|_{op} = \|T^*\|_{op}$. Therefore, $\|L^*\|_{op} \leq \sqrt{B}$. The frame operator is the mapping $S : H \to H$ defined as $S = L^*L$, i.e.,

$$\forall x \in H, \quad Sx = \sum_{j \in J} \langle x, x_j \rangle x_j. $$

Theorem 2.3 (Frame reconstruction formula). Let $H$ be a separable Hilbert space, and let $X = \{x_j\}_{j \in J} \subseteq H$.

a. $X$ is a frame for $H$ with frame bounds $A$ and $B$ if and only if $S : H \to H$ is a topological isomorphism with norm bounds $\|S\|_{op} \leq B$ and $\|S^{-1}\|_{op} \leq A^{-1}$, see [25], pages 100–104, for a proof.

b. In the case of either condition of part a, we have the following: $\{S^{-1} x_j\}$ is a frame for $H$ with frame bounds $B^{-1}$ and $A^{-1}$, and

$$\forall x \in H, \quad x = \sum_{j \in J} \langle x, x_j \rangle S^{-1} x_j = \sum_{j \in J} \langle x, S^{-1} x_j \rangle x_j = \sum_{j \in J} \langle x, S^{-1/2} x_j \rangle S^{-1/2} x_j, $$

see [39], [18] Chapters 3 and 7, and [35].

Let $X = \{x_j\}_{j \in J}$ be a frame for $H$. Then, the frame operator $S$ is a multiple of the identity precisely when $X$ is a tight frame. Further, $S^{-1}$ is a positive self-adjoint operator and has a square root $S^{-1/2}$ (Theorem 12.33 in [106]). This square root can be written as a power series in $S^{-1}$: consequently, it commutes with every operator that commutes with $S^{-1}$, and, in particular, with $S$. These properties allow us to assert that $\{S^{-1/2} x_j\}$ is a Parseval frame for $H$, and give the third equality of (7). see [35], page 155.

Definition 2.4 (Canonical dual). Let $X = \{x_j\}_{j \in J}$ be a frame for a separable Hilbert space $H$ with frame operator $S$. The frame $S^{-1}X = \{S^{-1} x_j\}_{j \in J}$ is the canonical dual frame of $X$. The frame $S^{-1/2}X = \{S^{-1/2} x_j\}_{j \in J}$ is the canonical tight frame of $X$.

The Gramian operator is the mapping $G : \ell^2(J) \to \ell^2(J)$ defined as $G = LL^*$. If $\{x_j\}_{j \in J}$ is the standard orthonormal basis for $\ell^2(J)$, then

$$\forall a = \{a_j\}_{j \in J} \in \ell^2(J), \quad \langle Ga, x_k \rangle = \sum_{j \in J} a_j \langle x_j, x_k \rangle. $$
2.2. FUNTFs. We shall often deal with FUNTFs \( X = \{ x_j \}_{j=1}^N \) for \( \mathbb{C}^d \).

The most interesting setting is for the case when \( N > d \). In fact, frames can provide redundant signal representation to compensate for hardware errors, can ensure numerical stability, and are a natural model for minimizing the effects of noise. Particular areas of recent applicability of FUNTFs include the following topics:

- Robust transmission of data over erasure channels such as the internet, e.g., see [32, 61, 62];
- Multiple antenna code design for wireless communications, e.g., see [78];
- Multiple description coding, e.g., see [62, 112];
- Quantum detection, e.g., see [21, 28, 56];
- Grassmannian “min-max” waveforms, e.g., see [22, 31, 112].

The following is a consequence of (6).

**Theorem 2.5** (FUNTF expansion). If \( X = \{ x_j \}_{j=0}^{N-1} \) is a FUNTF for \( \mathbb{F}^d \), then

\[
\forall x \in \mathbb{F}^d, \quad x = \frac{d}{N} \sum_{j=0}^{N-1} \langle x, x_j \rangle x_j.
\]

**Remark 2.6.** FUNTFs can be characterized as the minima of a potential energy function, see [17] for the details of this result.

Orthonormal bases for \( H = \mathbb{F}^d \) are both Parseval frames and FUNTFs. If \( X = \{ x_j \}_{j=0}^{N-1} \) is Parseval for \( H \) and each \( \| x_j \| = 1 \), then \( N = d \) and \( X \) is an ONB for \( H \). If \( X \) is a FUNTF with frame constant \( A \), then \( A \neq 1 \) if \( X \) is not an ONB. Further, a FUNTF \( X \) is not a Parseval frame unless \( N = d \) and \( X \) is an ONB; and, similarly, a Parseval frame is not a FUNTF unless \( N = d \) and \( X \) is an ONB.

Let \( X = \{ x_j \}_{j=0}^{N-1} \) be a Parseval frame. Then, each \( \| x_j \| \leq 1 \). If \( X \) is also equiangular, that is, \( |\langle x_j, x_k \rangle| \) is a constant as all \( j \neq k \) vary, then each \( \| x_j \| < 1 \), whereas we can not conclude that any \( \| x_j \| \) ever equals an \( \| x_k \| \) unless \( j = k \).

2.3. Naimark’s theorem. The following theorem, a weak variant of Naimark’s dilation theorem, tells us every Parseval frame is the projection of an orthonormal basis in a larger space. The general form of Naimark’s dilation theorem is a result for an uncountable family of increasing operators on a Hilbert space satisfying some additional conditions. It states that it is possible to construct an embedding into a larger space such that the dilations of the operators to this larger space commute and are a resolution of the identity. For an excellent description of this dilation problem and an independent geometric proof of a finite version of Naimark’s dilation theorem see [40] by C. H. Davis. To see the connection of this general theorem with the one below, consider the finite sums of the rank one projections onto the subspaces spanned by elements of a Parseval frame.

**Theorem 2.7** (Naimark’s theorem, e.g., [1, 69]). A set \( X = \{ x_j \}_{j \in J} \) in a Hilbert space \( H \) is a Parseval frame for \( H \) if and only if there is a Hilbert space \( K \) containing \( H \) and an orthonormal basis \( \{ e_j \}_{j \in J} \) for \( K \) such that the orthogonal projection \( P \) of \( K \) onto \( H \) satisfies

\[
\forall j \in J, \quad P e_j = x_j.
\]

**Remark 2.8.** If \( X \) is a Parseval frame for \( H \), then \( L^* L = I \), and so \( G^2 = LL^* LL^* = LL^* = G \). Hence, \( G \) is a projection, and since it is self-adjoint it is an orthogonal projection. Furthermore, \( G x_j = LL^* x_j = L x_j \). Thus, the orthogonal projection \( P \) onto \( L(H) \) from Naimark’s theorem is precisely \( G \).
2.4. DFT frames. The characters of the Abelian group $\mathbb{Z}/\mathbb{Z}$ are the functions $\{\gamma_n\}, n = 0, \ldots, N - 1$, defined by $m \mapsto e^{2 \pi i mn/N}$, so that the dual $(\mathbb{Z}/\mathbb{Z})$ is isomorphic to $\mathbb{Z}/\mathbb{Z}$ under the identification $\gamma_n \mapsto n$. Hence, the Fourier transform on $\ell^2(\mathbb{Z}/\mathbb{Z}) \simeq \mathbb{C}^N$ is a linear map that can be expressed as

$$\forall n \in \mathbb{Z}/\mathbb{Z}, \quad \hat{x}(n) = \sum_{m=0}^{N-1} x(m)e^{-2\pi i mn/N}. \tag{9}$$

It is elementary to see that the Fourier transform is defined by a linear transformation whose matrix representation is

$$D_N = (e^{-2\pi imn/N})_{m,n=0}^{N-1}. \tag{10}$$

The Fourier transform on $\mathbb{C}^N$ is called the discrete Fourier transform (DFT), and $D_N$ is the DFT matrix. The DFT has applications in digital signal processing and a plethora of numerical algorithms. Part of the reason why its use is so ubiquitous is that fast algorithms exist for its computation. The Fast Fourier Transform (FFT) allows the computation of the DFT to take place in $O(N \log N)$ operations. This is a significant improvement over the $O(N^2)$ operations it would take to compute the DFT directly by means of (9). The fundamental paper on the FFT is due to Cooley and Tukey [37], in which they describe what is now referred to as the Cooley-Tukey FFT algorithm. The algorithm employs a divide and conquer method going back to Gauss to break the $N$ dimensional DFT into smaller DFTs that may then be further broken down, computed, and reassembled. For a more extensive description of the DFT, FFT, and their relationship to sampling, sparsity, and the Fourier transform on $\ell^1(\mathbb{Z})$, see, e.g., [9, 60, 117].

**Definition 2.9** (DFT frame). Let $N \geq d$, and let $s : \mathbb{Z}/d \mathbb{Z} \to \mathbb{Z}/\mathbb{Z}$ be injective. For each $m = 0, \ldots, N-1$, set

$$x_m = (e^{2\pi i s(1)/N}, \ldots, e^{2\pi i s(d)/N}) \in \mathbb{C}^d,$$

and define the $N \times d$ matrix,

$$(e^{2\pi i s(n)/N})_{m,n}. \tag{11}$$

Then $X = \{x_m\}_{m=0}^{N-1}$ denotes its $N$ rows, and it is an equal-norm tight frame for $\mathbb{C}^d$ called a DFT frame.

The name comes from the fact that the elements of $X$ are projections of the rows of the conjugate of the ordinary DFT matrix (10). That $X$ is an equal-norm tight frame follows from Naimark’s theorem (Theorem 2.7) and the fact that the DFT matrix has orthogonal columns. In fact, $(1/\sqrt{N}) D_N$ is a unitary matrix. The rows of the $N \times d$ matrix in Definition 2.9, up to multiplication by $1/\sqrt{d}$, form a FUNTF for $\mathbb{C}^d$.

**Example 2.10** (DFT frame). If $d = 5$ and $N = 8$, then the function $s$ of Definition 2.9 determines 5 columns of the $8 \times 8$ DFT matrix, that, in turn, determine $\mathbb{C}^5$. Suppose these are columns 0, 2, 5, 6, 7, where the 8 columns of the $8 \times 8$ DFT matrix are listed as 0, $\ldots$, 7. Then, the resulting FUNTF for $\mathbb{C}^5$ consists of the vectors,

$$x_m = \frac{1}{\sqrt{5}} (1, e^{2\pi i m/2}, e^{2\pi i m/5}, e^{2\pi i m/6}, e^{2\pi i m/7}) \in \mathbb{C}^5, \quad m = 1, \ldots, 8.$$

For a given $N$, we shall use the notation, $\omega = e^{-2\pi i/N}$, and so $e_m = e^{2\pi im/N}$. Note that $\{e_m\}_{m=0}^{N-1}$ is a tight frame for $\mathbb{C}$.
3. The vector-valued discrete Fourier transform (DFT)

3.1. Definition and inversion theorem. In order to achieve the goals listed in Subsection 1.2, we shall also have to develop a vector-valued DFT theory to verify, not just motivate, that $A_p^d(u)$ is an STFT in the case $\{x_k\}_{k=0}^{N-1}$ is a DFT frame for $\mathbb{C}^d$.

We shall use the convention that the juxtaposition of vectors of equal dimension is the pointwise product of those vectors. Thus, for two functions, $u, v : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^d$, we let $uv$ be the coordinate-wise product of $u$ and $v$. This means that

$$\forall m \in \mathbb{Z}/N\mathbb{Z}, \quad (uv)(m) = u(m)v(m) \in \mathbb{C}^d,$$

where the product on the right is pointwise multiplication of vectors in $\ell^2(\mathbb{Z}/d\mathbb{Z})$, and so $u(m)(p), v(m)(p), (uv)(m)(p) \in \mathbb{C}$ for each $p \in \mathbb{Z}/d\mathbb{Z}$, i.e., $u(m)(p)$ designates the $p$th coordinate in $\mathbb{C}^d$ of the vector $u(m) \in \mathbb{C}^d$.

**Definition 3.1** (Vector-valued discrete Fourier transform). Let $\{x_k\}_{k=0}^{N-1}$ be a DFT frame for $\mathbb{C}^d$ with injective mapping $s$. Given $u : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^d$, the vector-valued discrete Fourier transform (vector-valued DFT) $\hat{u}$ of $u$ is defined by the formula,

$$\forall n \in \mathbb{Z}/N\mathbb{Z}, \quad F(u)(n) = \hat{u}(n) = \sum_{m=0}^{N-1} u(m)x_{-mn} \in \mathbb{C}^d,$$

where the product $u(m)x_{-mn}$ is pointwise (coordinate-wise) multiplication. Further, the mapping

$$F : \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \longrightarrow \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z})$$

is a linear operator.

We clarify (11) and (12) in the following remark.

**Remark 3.2.** Given $u : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^d$. We write $u \in \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z})$ as a function of the two arguments $m, p$ so that $u(m)(p) \in \mathbb{C}$. With this notation we can think of $u$ and $\hat{u}$ as $N \times d$ matrices with entries $u(m)(p)$ and $\hat{u}(n)(q)$, respectively.

In (11), the multiplication $-mn$ is mod $N$. Further, $x_{-mn} \in \mathbb{C}^d$ and $x_{-mn}(q) \in \mathbb{C}$ for each $0 \leq q \leq d - 1$. Hence, given $u : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^d$, we define $w \in \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z})$ by $w(m, p) = u(m)(p) \in \mathbb{C}$. Consequently, $F(u)(n)$ on the left side of (11) is really defined on $\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}$ as

$$F(u)(n, q) = \sum_{m=0}^{N-1} u(m)(q)x_{-mn}(q)$$

for $0 \leq q \leq d - 1$; and so we have

$$\forall q \in \mathbb{Z}/d\mathbb{Z}, \quad \hat{u}(n)(q) = \left( \sum_{m=0}^{N-1} u(m)x_{-mn} \right)(q)$$

$$= \left( \sum_{m=0}^{N-1} u(m)(q)x_{-mn}(q) \right).$$

From this we see that $\hat{u}(n)(q)$ depends only on $\{u(m)(q)\}_{m=0}^{N-1}$, i.e., when thought of as matrices the $q$-th column of $\hat{u}$ depends only on the $q$-th column of $u$. 
Theorem 3.3 (Inversion theorem). The vector-valued DFT is invertible if and only if \( s \), the injective function defining the DFT frame, has the property that
\[
\forall n \in \mathbb{Z}/d\mathbb{Z}, \quad (s(n), N) = 1.
\]
In this case, the inverse is given by
\[
\forall m \in \mathbb{Z}/NZ, \quad u(m) = (P^{-1}\hat{u})(m) = \frac{1}{N} \sum_{p=0}^{N-1} \hat{u}(p)x_{mp};
\]
and we also have that \( F^*F = FF^* = NI \), where \( I \) is the identity operator.

Proof. We first show the forward direction. Suppose there is \( n_0 \in \mathbb{Z}/d\mathbb{Z} \) such that \( (s(n_0), N) \neq 1 \). Then there exists \( j, l, M \in \mathbb{N} \) such that \( j > 1 \), \( s(n_0) = jl \), and \( N = jM \). Define a matrix \( A \) as
\[
A = (e^{2\pi imks(n_0)/N})_{m,k=0}^{N-1} = (e^{2\pi imkl/M})_{m,k=0}^{N-1}.
\]
\( A \) has rank strictly less than \( N \) since the 0-th and \( M \)-th rows are all 1s. Therefore we can choose a vector \( v \in \mathbb{C}^N \) orthogonal to the rows of \( A \). Define \( u : \mathbb{Z}/NZ \to \mathbb{C}^d \) by
\[
u(m)(n) = \begin{cases} v(m) & \text{if } n = n_0 \\ 0 & \text{otherwise}. \end{cases}
\]
Then,
\[
\forall n \neq n_0, \quad \hat{u}(m)(n) = \sum_{k=0}^{N-1} u(k)(n)x_{mk}(n) = \sum_{k=0}^{N-1} 0 \cdot x_{mk}(n) = 0,
\]
while, for \( n = n_0 \), we have
\[
\hat{u}(m)(n_0) = \sum_{k=0}^{N-1} u(k)(n_0)x_{mk}(n_0) = \sum_{k=0}^{N-1} u(k)(n_0)e^{-2\pi imks(n_0)/N}
\]
\[
= \sum_{k=0}^{N-1} u(k)(n_0)e^{-2\pi imkl/M} = \langle u(\cdot)(n_0), e^{2\pi im(\cdot)/M} \rangle = \langle v, e^{2\pi im(\cdot)/M} \rangle = 0.
\]
The final equality follows from the fact that \( v \) is orthogonal to the rows of \( A \). Hence, the vector-valued DFT defined by \( s \) has non-trivial kernel and is not invertible.

We prove the converse and the formula for the inverse with a direct calculation. We compute
\[
\sum_{n=0}^{N-1} \hat{u}(n)x_{mn} = \sum_{n=0}^{N-1} \left( \sum_{k=0}^{N-1} u(k)x_{kn} \right) x_{mn}
\]
\[
= \sum_{k=0}^{N-1} \left( u(k) \left( \sum_{n=0}^{N-1} x_{n(m-k)} \right) \right).
\]
The $r$-th component of the last summation is
\[
\sum_{n=0}^{N-1} x_{n(m-k)}(r) = \sum_{n=0}^{N-1} e^{2\pi i n(m-k)s(r)/N}
\]
\[
= \begin{cases} 
N & \text{if } (m-k)s(r) \equiv 0 \mod N \\
0 & \text{if } (m-k)s(r) \not\equiv 0 \mod N.
\end{cases}
\]

Since $(s(r), N) = 1$, the first cases occurs if and only if $k = m$. Continuing with the previous calculation, we have
\[
\sum_{k=0}^{N-1} \left( u(k) \left( \sum_{n=0}^{N-1} x_{n(m-k)} \right) \right) = Nu(m).
\]

Finally, we compute the adjoint of $F$.

\[
\langle Fu, v \rangle = \sum_{m=0}^{N-1} \sum_{n=0}^{d-1} \hat{u}(m)(n)\overline{v(m)(n)} = \sum_{m=0}^{N-1} \sum_{n=0}^{d-1} \left( \sum_{k=0}^{N-1} u(k)(n)x_{-mk}(n) \right) \overline{v(m)(n)}
\]
\[
= \sum_{k=0}^{N-1} \sum_{n=0}^{d-1} u(k)(n) \left( \sum_{m=0}^{N-1} v(m)(n)x_{mk}(n) \right) = \langle u, F^* v \rangle.
\]

Therefore, $F^*$ is defined by
\[
(F^* v)(k) = \sum_{m=0}^{N-1} v(m)x_{mk},
\]
and $F^* = NF^{-1}$. \qed

By Theorem 3.3, we can define the unitary vector-valued discrete Fourier transform $\mathcal{F}$ by the formula

\[
\mathcal{F} = \frac{1}{\sqrt{N}} F.
\]

With this definition, we have
\[
\mathcal{F} F^* = F^* \mathcal{F} = I,
\]
and $\mathcal{F}$ is unitary.

**Definition 3.4** (Translation and modulation). Let $u : \mathbb{Z}/NZ \to \mathbb{C}^d$, and let $\{x_k\}_{k=0}^{N-1}$ be a DFT frame for $\mathbb{C}^d$. For each $j \in \mathbb{Z}/NZ$, define the translation operators,

\[
\tau_j : \ell^2(\mathbb{Z}/NZ \times \mathbb{Z}/d\mathbb{Z}) \to \ell^2(\mathbb{Z}/NZ \times \mathbb{Z}/d\mathbb{Z}), \quad \tau_j u(m) = u(m-j),
\]

and the modulation operators,

\[
e^j : \mathbb{Z}/NZ \to \mathbb{C}^d, \quad e^j(k) = x_{jk}.
\]

The usual translation and modulation properties of the Fourier transform hold for the vector-valued transform.
Theorem 3.5 (The DFT of translation and modulation). Let \( u : \mathbb{Z}/NZ \to \mathbb{C}^d \), and let \( \{x_k\}_{k=0}^{N-1} \) be a DFT frame for \( \mathbb{C}^d \) with associated vector-valued discrete Fourier transform \( F \). Then,

\[
F(\tau_j u) = e^{-j\hat{u}}
\]

and

\[
F(e^j u) = \tau_j \hat{u}.
\]

Proof. i. We compute

\[
\hat{\tau_j u}(n) = \sum_{m=0}^{N-1} \tau_j u(m)x_{mn} = \sum_{m=0}^{N-1} u(m - j)x_{mn} = \sum_{k=-j}^{N-1-j} u(k)x_{-(k+j)n}
\]

\[
= \sum_{k=0}^{N-1} u(k)x_{-kn-jn} = x_{-jn} \left( \sum_{k=0}^{N-1} u(k)x_{-kn} \right) = x_{-jn}\hat{u}(n).
\]

The third equality follows by setting \( k = m - j \), the fourth by reordering the sum and noting that the index of summation is modulo \( N \), and the fifth follows since \( x_{j+k} = x_jx_k \) and by the bilinearity of pointwise products.

ii. We compute

\[
\hat{e^j u}(n) = \sum_{m=0}^{N-1} (e^j u)(m)x_{mn} = \sum_{m=0}^{N-1} x_{jn} u(m)x_{mn}
\]

\[
= \sum_{m=0}^{N-1} u(m)x_{m(n-j)} = \hat{u}(n-j).
\]

The third equality follows from commutativity and since \( x_{j+k} = x_jx_k \). \( \square \)

3.2. A matrix formulation of the vector-valued DFT. We now describe a different way of viewing the vector-valued DFT that makes some properties more apparent. Given \( N \in \mathbb{N} \), define the matrices \( D_\ell \),

\[
\forall \ell \in \mathbb{Z}/NZ, \quad D_\ell = (e^{-2\pi i m n \ell / N})_{m,n=0}^{N-1}.
\]

By definition of the vector-valued DFT, we have

\[
\hat{u}(n)(q) = \left( \sum_{m=0}^{N-1} u(m)(q)x_{mn}(q) \right)
\]

\[
= \left( \sum_{m=0}^{N-1} u(m)(q)e^{-2\pi i mns(q)/N} \right) = (D_{s(q)}u(\cdot)(q))(n),
\]

i.e., the vector \( \hat{u}(\cdot)(q) \) is equal to the vector \( D_{s(q)}u(\cdot)(q) \). In other words, we obtain \( \hat{u} \) by applying the matrix \( D_{s(q)} \) to the \( q \)-th column of \( u \) for each \( 0 \leq q \leq d-1 \). Therefore, \( F \) is invertible if and only if each matrix \( D_{s(q)} \) is invertible.

The rows of \( D_\ell \) are a subset of the rows of the DFT matrix, and each row of the DFT matrix is a character of \( \mathbb{Z}/NZ \). Taken as a collection, the characters form the dual group \( \widehat{(\mathbb{Z}/NZ)} \simeq \mathbb{Z}/NZ \) under pointwise multiplication. With this group operation and the fact that

\[
\forall m, n \in \mathbb{Z}/NZ, \quad e^{-2\pi i m \ell / N} = (e^{-2\pi i n \ell / N})^m,
\]
we see the rows of \( D_κ \) are the orbit of some element \( γ \in (ℤ/NN\hat{Z}) \) repeated \(|γ|/N \) times. Hence, \( D_κ \) is invertible if and only if \( γ \) generates the entire dual group. From the theory of cyclic groups, \( γ \) is a generator of \((ℤ/NN\hat{Z})\) if and only if \( γ = (e^{-2πinℓ/N})_{n=0}^{N-1} \) for some \( ℓ \) relatively prime to \( N \). Therefore, \( F \) is invertible if and only if \( s(q) \) is relatively prime to \( N \) for each \( q \).

**Example 3.6** (Invertibility of Fourier matrices). Let \( N = 4 \) and recall that \( ω = e^{-2πi/4} \). We compute the matrices \( D_1, D_2, \) and \( D_3 \).

\[
D_1 = \begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & ω & ω^2 & ω^3 \\
1 & ω^2 & 1 & ω^2 \\
1 & ω^3 & ω^2 & ω
\end{pmatrix} \quad D_2 = \begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & ω^2 & 1 & ω^2 \\
1 & 1 & 1 & 1 \\
1 & ω^2 & 1 & ω^2
\end{pmatrix} \quad D_3 = \begin{pmatrix}
1 & 1 & 1 & 1 \\
1 & ω^3 & 1 & ω \\
1 & ω^2 & ω^2 & ω \\
1 & ω^1 & ω^2 & ω^3
\end{pmatrix}
\]

It is easy to see that \( D_1 \) and \( D_3 \) are invertible while \( D_2 \) is not invertible. In each case the matrix \( D_κ \) is generated by pointwise powers of its second row, which have orders 4, 2, and 4 respectively. In fact, the full vector-valued DFT can be viewed as a block matrix, where the \( q \)th block is \( D_{s(q)} \).

**Remark 3.7.** Using our definition of the vector-valued DFT, that we first published in [16] (2008), Soto-Quiros [108] has proven the inversion formula in term of block matrices. We should point out that our proof of the inversion formula was not included in [16] because of space limitations of Asilomar conference publications. The proof is included above and it is substantially different than that of Soto-Quiros.

### 3.3. The Banach algebra of the vector-valued DFT

We now study the vector-valued DFT in terms of Banach algebras. In fact, we shall define a Banach algebra structure on \( A = L^1(ℤ/NN\hat{Z} \times ℤ/d\hat{Z}) \), describe the spectrum \( σ(A) \) of \( A \), and then prove that the Gelfand transform of \( A \) is the vector-valued DFT.

To this end, first recall that if \( G \) is a locally compact Abelian group (LCAG), then \( L^1(G) \) is a commutative Banach algebra under convolution.

Next, let \( B \) be a commutative Banach \(*\)-algebra over \( ℂ \), where \(*\) indicates the involution satisfying the properties, \((x + y)^* = x^* + y^*, (cx)^* = c^*x^*, (xy)^* = y^*x^* \), and \( x^{**} = x \) for all \( x, y \in B \) and \( c \in ℂ \). For example, let \( B = L^1(G) \) and define \( f^*(t) = \overline{f(-t)} \) for \( f \in L^1(G) \).

The spectrum \( σ(B) \) of \( B \) is the set of non-zero homomorphisms, \( h : B \to ℂ \). \( σ(B) \) is subset of the weak \(*\)-compact unit ball of the dual space \( B' \) of the Banach space \( B \), and each \( x \in B \) defines a function \( \hat{x} : σ(B) \to ℂ \) given by

\[
\forall h \in σ(B), \quad \hat{x}(h) = h(x).
\]

\( \hat{x} \) is the Gelfand transform of \( x \). We shall use well-known properties of the Gelfand transform, e.g., see [54, 59, 75, 76, 98, 101, 105].

Using the group structure on \( ℤ/NN\hat{Z} \times ℤ/d\hat{Z} \), we define the convolution of \( u, v \in A = L^1(ℤ/NN\hat{Z} \times ℤ/d\hat{Z}) \) by the formula,

\[
(u \ast v)(m)(n) = \sum_{k=0}^{N-1} \sum_{l=0}^{d-1} u(k)(l)v(m-k)(n-l).
\]

This definition is not ideal for our purposes because it treats \( u \) and \( v \) as functions that take \( Nd \) values. Our desire is to view \( u \) and \( v \) as functions that take \( N \) values, that are each \( d \)
The convolution (13) can be rewritten as

\[(u \ast v)(m)(n) = \sum_{k=0}^{N-1} (u(k) \ast v(m - k))(n),\]

where the \(\ast\) on the right hand side is \(d\)-dimensional convolution. Replacing this \(d\)-dimensional convolution with pointwise multiplication, we arrive at the following new definition of convolution on \(\mathcal{A}\).

**Definition 3.8 (Vector-valued convolution).** Let \(u, v \in \mathcal{A}\). Define the vector-valued convolution of \(u\) and \(v\) by the formula

\[(u \ast_v v)(m) = \sum_{k=0}^{N-1} u(k)v(m - k).\]

**Theorem 3.9 (Properties of \(\mathcal{A}\)).** \(\mathcal{A}\) equipped with the vector-valued convolution \(\ast_v\) is a commutative Banach \(*\)-algebra with unit \(e\) defined as

\[e(m) = \begin{cases} 1 & m = 0 \\ 0 & m \neq 0, \end{cases}\]

where \(\mathbf{1}\) and \(\mathbf{0}\) are the vectors of 1s and 0s, respectively, and with involution defined as \(u^*(m) = u(-m)\).

**Proof.** It is essentially only necessary to verify that \(\|u \ast_v v\|_1 \leq \|u\|_1 \|v\|_1\) is valid. We compute

\[\|u \ast_v v\|_1 = \sum_{m=0}^{N-1} \|u \ast v(m)\|_{L^1(\mathbb{Z}/d\mathbb{Z})} = \sum_{m=0}^{N-1} \left\| \sum_{k=0}^{N-1} u(k)v(m - k) \right\|_{L^1(\mathbb{Z}/d\mathbb{Z})}
\leq \sum_{m=0}^{N-1} \sum_{k=0}^{N-1} \|u(k)v(m - k)\|_{L^1(\mathbb{Z}/d\mathbb{Z})} \leq \sum_{m=0}^{N-1} \sum_{k=0}^{N-1} \|u(k)\|_{L^1(\mathbb{Z}/d\mathbb{Z})} \|v(m - k)\|_{L^1(\mathbb{Z}/d\mathbb{Z})}
= \sum_{k=0}^{N-1} \|u(k)\|_{L^1(\mathbb{Z}/d\mathbb{Z})} \sum_{m=0}^{N-1} \|v(m - k)\|_{L^1(\mathbb{Z}/d\mathbb{Z})} = \sum_{k=0}^{N-1} \|u(k)\|_{L^1(\mathbb{Z}/d\mathbb{Z})} \|v\|_1 = \|u\|_1 \|v\|_1.\]

\[\square\]

Tying this together with our DFT theory, we have the following desired theorem relating \(\mathcal{A}\) to the vector-valued DFT.

**Theorem 3.10 (Convolution theorem).** Let \(u, v \in \mathcal{A}\). The vector-valued Fourier transform of the convolution of \(u\) and \(v\) is the vector product of their Fourier transforms, i.e.,

\[F(u \ast_v v) = F(u)F(v).\]

**Proof.**

\[F(u \ast_v v)(n) = \sum_{m=0}^{N-1} (u \ast v)(m)x_{-mn} = \sum_{m=0}^{N-1} \left( \sum_{k=0}^{N-1} u(k)v(m - k) \right)x_{-mn}
= \sum_{k=0}^{N-1} u(k) \left( \sum_{m=0}^{N-1} v(m - k)x_{-mn} \right) = \sum_{k=0}^{N-1} u(k) \left( \sum_{l=0}^{N-1} v(l)x_{-(k+l)n} \right)\]
\[
\left( \sum_{k=0}^{N-1} u(k)x_{-kn} \right) \left( \sum_{l=0}^{N-1} v(l)x_{-ln} \right) = F(u)(n)F(v)(n).
\]

We shall now describe the spectrum of \( A \) and the Gelfand transform of \( A \), see Theorem 3.11.

Define functions \( \delta_{(i,j)} \) in \( A \) by
\[
\delta_{(i,j)}(m)(n) = \begin{cases} 1 & (m,n) = (i,j) \\ 0 & \text{otherwise.} \end{cases}
\]

It is easy to see that \( \delta_{(i,j)}^k = \delta_{(1,j)} \ast \ldots \ast \delta_{(1,j)} \) (k factors) = \( \delta_{(k,j)} \) so that \( \{\delta_{(1,j)}\}_{j=0}^{d-1} \) generate \( A \). We shall find the spectrum of the individual elements of our generating set \( \{\delta_{(1,j)}\}_{j=0}^{d-1} \), and with this information describe the spectrum of \( A \).

To find the spectrum of \( \delta_{(1,j)} \) we first find necessary conditions on \( \lambda \) for \( (\lambda e - \delta_{(1,j)})^{-1} \) to exist, and when these conditions are met we compute \( (\lambda e - \delta_{(1,j)})^{-1} \) and thereby show the conditions are sufficient as well. To that end, suppose \( u = (\lambda e - \delta_{(1,j)})^{-1} \) exists, i.e., \( (\lambda e - \delta_{(1,j)}) \ast u = e \). Expanding the definitions on the left hand side
\[
(\lambda e - \delta_{(1,j)}) \ast u(m) = \sum_{k=0}^{N-1} (\lambda e - \delta_{(1,j)})(k)u(m-k)
\]
\[
= \lambda u(m) - \delta_{(1,j)}(1)u(m-1).
\]

Setting the result equal to \( e(m) \) and dividing into the cases \( m = 0 \) and \( m \neq 0 \) yields two equations
(14) \quad \forall n \in \mathbb{Z}/d\mathbb{Z}, \quad \lambda u(0)(n) - \delta_{(1,j)}(1)(n)u(N-1)(n) = 1

and
(15) \quad \forall n \in \mathbb{Z}/d\mathbb{Z} and \forall m \in \mathbb{Z}/N\mathbb{Z} \setminus \{0\}, \quad \lambda u(m)(n) - \delta_{(1,j)}(1)(n)u(m-1)(n) = 0.

Substituting \( n = j \) into (14) yields
(16) \quad \lambda u(0)(j) - u(N-1)(j) = 1,

while for \( n \neq j \) we have
\[
u(0)(n) = \frac{1}{\lambda}.
\]

Therefore, we must have \( \lambda \neq 0 \). Similarly, substituting \( n = j \) in (15) gives
(17) \quad \forall m \neq 0, \quad \lambda u(m)(j) - u(m-1)(j) = 0,

while
\[
\forall n \neq j, \forall m \neq 0, \quad u(m)(n) = 0.
\]

At this point and for our fixed \( j \) we have specified all the values of \( u \) except for \( u(m)(j) \). Now, iterate (17) \( N-1 \) times to find
(18) \quad \lambda^{N-1}u(N-1)(j) - u(0)(j) = 0.

Finally, multiplying (18) by \( \lambda \) and adding it to equation (16) we obtain
\[
(\lambda^N - 1)u(N-1)(j) = 1,
\]
and hence $\lambda^N \neq 1$. Using (17) we can find the remaining values of $u(m)(j)$:

$$u(m)(j) = \frac{\lambda^{N-m-1}}{\lambda^N - 1}.$$  

This completes the computation of $u$. We have shown that, for $\lambda e - \delta_{(1,j)}$ to be invertible, $\lambda$ must satisfy $\lambda \neq 0$ and $\lambda^N \neq 1$. Given that $\lambda$ meets these requirements we found an explicit inverse; therefore $\sigma(\delta_{(1,j)}) = \{0, \lambda : \lambda^N = 1\}$.

By the Riesz representation theorem, a linear functional on $\mathcal{A}$ is given by integration against a function $\gamma \in L^\infty(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z})$, which we can also view simply as an $N \times d$ matrix. Further, a basic result in the Gelfand theory is that, for a commutative Banach algebra with unit, we have $\hat{x}(\sigma(\mathcal{A})) = \sigma(x)$ (Theorem 1.13 of [54]). Combining this with our previous calculations, it follows that for a multiplicative linear functional $\gamma$,

$$\overline{\gamma(1)(n)} = \int \delta_{(1,n)} \gamma = \gamma(\delta_{(1,n)}) \in \sigma(\delta_{(1,n)}).$$

Since $\gamma$ is multiplicative,

$$\overline{\gamma(m)(n)} = \int \delta_{(m,n)} \gamma = \int \delta_{(1,n)}^m \gamma = \gamma(\delta_{(1,n)})^m,$$

taking the values 0 or $\lambda^m$ where $\lambda^N = 1$. Therefore $\gamma(0)(n)$ is 0 or 1, and since

$$1 = \gamma(e) = \sum_{k=0}^{d-1} \overline{\gamma(0)(k)},$$

we have $\gamma(0)(n) \neq 0$ (and thus $\gamma(1)(n) \neq 0$) for only one $n$. It follows that for this $n$, $\gamma(1)(n) = \overline{\lambda}$ where $\lambda^N = 1$.

We have everything we need to describe $\sigma(\mathcal{A})$. The multiplicative linear functionals on $\mathcal{A}$ are $N \times d$ matrices of the form

$$\gamma_{\lambda,k}(m)(n) = \begin{cases} 
\lambda^{-m} & \text{for } n = k, \\
0 & \text{otherwise},
\end{cases} \quad \text{where } \lambda^N = 1, \quad 0 \leq k \leq d - 1.$$

Set $\omega = e^{-2\pi i/N}$. If $\lambda^N = 1$, then $\lambda = \omega^j$ for some $0 \leq j \leq N - 1$, and we can write $\gamma_{\lambda,k}$ as $\gamma_{j,k}$. Thus, we can list all the elements of $\sigma(\mathcal{A})$ as $\{\gamma_{j,k}\}$, $0 \leq j \leq N - 1$, $0 \leq k \leq d - 1$, and there are $Nd$ of them.

Let $s : \mathbb{Z}/d\mathbb{Z} \to \mathbb{Z}/N\mathbb{Z}$ be injective and have the property that for every $n \in \mathbb{Z}/d\mathbb{Z}$, $(s(n), N) = 1$, i.e., the vector-valued DFT defined by $s$ is invertible. Using $s$, we can reorder $\sigma(\mathcal{A})$ as follows. For $0 \leq p \leq N - 1$ and $0 \leq q \leq d - 1$, define $\gamma'_{p,q}$ by

$$\gamma'_{p,q}(m)(n) = \begin{cases} 
\omega^{-pms(q)} & \text{for } n = q, \\
0 & \text{otherwise}.
\end{cases}$$

We claim $\{\gamma'_{p,q}\}_{p,q}$ is a reordering of $\{\gamma_{j,k}\}_{j,k}$. To show this, first note that $\{\gamma'_{p,q}\}_{p,q} \subseteq \{\gamma_{j,k}\}_{j,k}$. To demonstrate the reverse inclusion, for each $q \in \mathbb{Z}/d\mathbb{Z}$ find a multiplicative inverse to $s(q)$ in $\mathbb{Z}/N\mathbb{Z}$. This may be done because $(s(q), N) = 1$ for every $q$. Writing this inverse as $s(q)^{-1}$, it follows that

$$\gamma'_{j,(s(k))^{-1},k} = \gamma_{j,k},$$

and therefore $\{\gamma_{j,k}\}_{j,k} \subseteq \{\gamma'_{p,q}\}_{p,q}$.

We summarize all of these calculations as the following theorem.
Theorem 3.11 (Spectrum and Gelfand transform of $\mathcal{A}$). The spectrum, $\sigma(\mathcal{A})$, of $\mathcal{A}$ is identified with $\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}$ by means of the mapping $\gamma'_{p,q} \leftrightarrow (p,q)$. Under this identification, the Gelfand transform, $\hat{x} \in C(\sigma(\mathcal{A}))$, of $x \in \mathcal{A}$, is the $N \times d$ matrix,

$$
\hat{x}(p)(q) = \hat{x}(\gamma'_{p,q}) = \gamma'_{p,q}(x) = \sum_{m=0}^{N-1} x(m)(q) \omega^{pms(q)} = \sum_{m=0}^{N-1} x(m)(q) e^{-2\pi ipms(q)/N}.
$$

In particular, under the identification, $\gamma'_{p,q} \leftrightarrow (p,q)$, the Gelfand transform of $\mathcal{A}$ is the vector-valued DFT.

While this shows that the transform we have defined is itself not new, it also shows that a classical transform can be redefined in the context of frame theory.

Example 3.12 (Vector-valued functions and commutative Banach algebras). a. In the spirit of our analysis of $\mathcal{A}$, but not the same mathematically, a generalization for the harmonic analysis of vector valued functions, $u : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^d$, is to consider the space $L^1(G,V)$. Here, $G$ is a locally compact Abelian group and $V$ is a commutative Banach algebra, so that $L^1(G,V)$ is defined as the space of $V$-valued Bochner integrable functions on $G$ with respect to Haar Measure on $G$, cf. another direction of generalization with regard to POVMs, see Example 6.11 As such, $L^1(G,V)$ is a commutative Banach algebra, where $G$ has replaced $\mathbb{Z}/N\mathbb{Z}$ and $V$ has replaced $\mathbb{C}^d$.

To have developed our theory in the generality of $L^1(G,V)$ would have obviated the applicable roots and future of our approach, and, more fundamentally, would have severely restricted finding and proving properties of the theory, e.g., the number theoretic role in this section necessary for defining the vector-valued DFT.

On the other hand, the study of objects such as $L^1(G,V)$ allows us to formulate structural qustions. For example, A. Hausner [71] and G. P. Johnson [82], both in 1956, proved that the maximal ideal space of $L^1(G,V)$ is homeomorphic to the cartesian product of the dual group of $G$ with the maximal ideal space of $V$, taken with the appropriate topologies. Knowledge of the ideal structure of Banach algebras is equivalent to the understanding of spectral synthesis reconstruction in these algebras, and parallels the knowledge of ideal structure in algebraic geometry associated with results such as the Nullstellensatz, see [6], page 42. The study of spectral synthesis for $L^1(G)$ goes back to Wiener’s Tauberian theorem and the classical formulation of Beurling, e.g., [6]. Because of the Grothendieck theory [64], $L^1(G,V)$ is a projective tensor product, and such products have had significant implications in abstract harmonic analysis associated with spectral synthesis, see [6], Section 3.1 and the references there. The projective tensor product technology also leads to generalization beyond $L^1(G,V)$, see [90].

b. The maximal ideal space of $L^1(G,V)$ and spectral synthesis were introduced in part a. Another fundamental object of study in harmonic analysis is that of a multiplier. A classic treatise on the subject is due to R. Larsen [87]. A multiplier $L : L^1(G,V) \to L^1(G,V)$ is a continuous linear mapping with the properties that $L \tau_g = \tau_g L$ for all $g \in G$ and $L(vf) = vL(f)$ for all $v \in V, f \in L^1(G,V)$. The first condition should be compared with the two conclusions of Theorem 3.5. Let $M(L^1(G,V))$ be the space of multipliers taken with the natural topology on spaces of continuous linear mappings, and let $\mathcal{M}(G,V)$ be the
space of bounded $V$-valued measures taken with its natural dual space topology from the Riesz representation theorem. Tewari, Dutta, and Vaidya [118] proved that $M(L^1(G, V))$ and $\mathcal{M}(G, V)$ are isometrically isomorphic in the case that $V$ has an identity: and there have been generalizations, e.g., see [100].

4. Formulation of generalized scalar- and vector-valued ambiguity functions

4.1. Formulation. Given $u : \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}^d$. A periodic vector-valued ambiguity function $A_p^d(u) : \mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}^d$ was defined in [16] by observing the following. If $d = 1$, then $A_p(u)$ in Equation (2) can be written as

\[
A_p(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} \langle u(m + k), u(k) e_{kn} \rangle
\]

(19)

where $\tau_m$ is the translation operator of Definition 3.4 and where $F^{-1}$ is the inverse DFT on $\mathbb{Z}/N\mathbb{Z}$. In particular, we see that $A_p(u)$ has the form of a STFT, see Example 4.3. This is central to our approach.

If $d > 1$, then, motivated by the calculation (19), it turns out that we can define both a $\mathbb{C}$-valued ambiguity function $A_p^1(u)$ and a $\mathbb{C}^d$-valued function $A_p^d(u)$.

First, we consider the case of a $\mathbb{C}$-valued ambiguity function. Inspired by (19), and for $u : \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}^d$, we wish to construct a sequence $\{x_n\}_{n=0}^{N-1} \subseteq \mathbb{C}^d$ and define a vector multiplication $\ast$ in $\mathbb{C}^d$ so that the mapping, $A_p^1(u) : \mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}$, given by

\[
A_p^1(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} \langle u(m + k), u(k) \ast x_k \rangle
\]

(20)

is a meaningful ambiguity function. The product, $kn$, is modular multiplication in $\mathbb{Z}/N\mathbb{Z}$. In Subsections 4.2 and 4.4, we shall see that in quite general circumstances, for the proper $\{x_n\}_{n=0}^{N-1}$ and $\ast$, Equation (20) can be made compatible with that of $A_p(u)$ in (19).

Second, we consider the case of a $\mathbb{C}^d$-valued ambiguity function. In the context of our definition of $A_p^1(u)$, we formulate the vector-valued version, $A_p^d(u)$, of the periodic ambiguity function as follows. Let $u : \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}^d$, and define the mapping, $A_p^d(u) : \mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{C}^d$, by

\[
A_p^d(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} u(m + k) \ast \overline{u(k)} \ast x_k
\]

(21)

where $\{x_n\}_{n=0}^{N-1}$ and $\ast$ must also be constructed and defined, respectively. In Example 4.3, we shall see that this definition is compatible with that of $A_p(u)$ in (19).

To this end of defining $A_p^d(u)$, and motivated by the facts that $\{e_n\}_{n=0}^{N-1}$ is a tight frame for $\mathbb{C}$ (as noted in Subsection 2.4) and $e_m e_n = e_{m+n}$, the following frame multiplication assumptions were made in [16].
• There is a sequence $X = \{x_n\}_{n=0}^{N-1} \subseteq \mathbb{C}^d$ and a multiplication $\ast : \mathbb{C}^d \times \mathbb{C}^d \to \mathbb{C}^d$ such that

$$\forall m, n \in \mathbb{Z}/NZ, \quad x_m \ast x_n = x_{m+n};$$

(22)

• $X = \{x_n\}_{n=0}^{N-1}$ is a tight frame for $\mathbb{C}^d$;

• The multiplication $\ast$ is bilinear, in particular,

$$\left(\sum_{j=0}^{N-1} c_j x_j\right) \ast \left(\sum_{k=0}^{N-1} d_k x_k\right) = \sum_{j=0}^{N-1} \sum_{k=0}^{N-1} c_j d_k x_j \ast x_k.$$

There exist tight frames satisfying these assumptions, e.g., DFT frames. We shall characterize such tight frames and multiplications in Sections 5, 6, and 7.

A reason we developed our vector-valued DFT theory of Section 3 was to verify, not just motivate, that $A_d^p(u)$ is a STFT in the case $\{x_k\}_{k=0}^{N-1}$ is a DFT frame for $\mathbb{C}^d$. Let $X = \{x_n\}_{n=0}^{N-1}$ be a DFT frame for $\mathbb{C}^d$. We can leverage the relationship between the bilinear product pointwise multiplication and the operation of addition on the indices of $X$, i.e., $x_m x_n = x_{m+n}$, to define the periodic vector-valued ambiguity function $A_d^p(u)$ as in Equation (21). In this case, the DFT frame is acting as a high dimensional analog to the roots of unity $\{\omega_n = e^{2\pi i n/N}\}_{n=0}^{N-1}$, that appear in the definition of the usual periodic ambiguity function.

Example 4.1 (Multiplication problem). Given $u : \mathbb{Z}_N \longrightarrow \mathbb{C}^d$. If $d = 1$ and $x_n = e^{2\pi i n/N}$, then Equations (2) and (19) can be written as

$$A_p(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} \langle u(m+k), u(k) x_n \rangle.$$

The multiplication problem for $A_k^1(u)$ is to characterize sequences $\{x_k\} \subseteq \mathbb{C}^d$ and multiplications $\ast$ so that

$$A_k^1(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} \langle u(m+k), u(k) \ast x_n \rangle \in \mathbb{C}$$

is a meaningful and well-defined ambiguity function. This formula is clearly motivated by the STFT. It is for this reason that we made the frame multiplication assumptions.

In fact, suppose $\{x_j\}_{j=0}^{N-1} \subseteq \mathbb{C}^d$ satisfies the three frame multiplication assumptions. If we are given $u, v : \mathbb{Z}/NZ \longrightarrow \mathbb{C}^d$ and $m, n \in \mathbb{Z}/NZ$, then we can make the calculation,

$$u(m) \ast v(n) = \frac{d}{N} \sum_{j=0}^{N-1} \langle u(m), x_j \rangle x_j \ast \frac{d}{N} \sum_{s=0}^{N-1} \langle v(n), x_s \rangle x_s$$

(23)

$$= \frac{d^2}{N^2} \sum_{j=0}^{N-1} \sum_{s=0}^{N-1} \langle u(m), x_j \rangle \langle v(n), x_s \rangle x_j \ast x_s$$

$$= \frac{d^2}{N^2} \sum_{j=0}^{N-1} \sum_{s=0}^{N-1} \langle u(m), x_j \rangle \langle v(n), x_s \rangle x_{j+s}.$$
4.2. $A_{1}^{d}(u)$ and $A_{p}^{d}(u)$ for DFT frames.

Example 4.2 (STFT formulation of $A_{1}^{d}(u)$). Given $u, v : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^{d}$, and let $X = \{x_k\}_{k=0}^{N-1} \subseteq \mathbb{C}^{d}$ be a DFT frame for $\mathbb{C}^{d}$. Suppose $\ast$ denotes pointwise (coordinatewise) multiplication times a factor of $\sqrt{d}$. Then, the frame multiplication assumptions are satisfied. To see this, and without loss of generality, choose the first $d$ columns of the $N \times N$ DFT matrix, and let $r$ designate a fixed column. Then, we can verify the first of the frame multiplication assumptions by the following calculation, where the first step is a consequence of Equation (23):

$$x_{m} \ast x_{n}(r) = \frac{d^{2}}{N^{2}} \sum_{j=0}^{N-1} \sum_{s=0}^{N-1} \langle x_{m}, x_{j} \rangle \langle x_{n}, x_{s} \rangle x_{j+s}(r).$$

$$= \frac{1}{N^{2} \sqrt{d}} \sum_{j=0}^{N-1} \sum_{s=0}^{N-1} \sum_{t=0}^{d-1} \sum_{k=0}^{d-1} x^{(m-j)t}x^{(n-s)k}x^{(j+s)r}$$

$$= \frac{1}{N^{2} \sqrt{d}} \sum_{t=0}^{d-1} \sum_{k=0}^{d-1} x_{mt+nk} \sum_{j=0}^{N-1} x^{(r-t)j} \sum_{s=0}^{N-1} x^{(r-k)s}$$

$$= \frac{1}{N^{2} \sqrt{d}} \sum_{t=0}^{d-1} \sum_{k=0}^{d-1} x_{mt+nk}N\delta(r-t)N\delta(r-k)$$

$$= \frac{x^{(m+n)r}}{\sqrt{d}} = x_{m+n}(r).$$

The second and third frame multiplication assumptions follow since $X$ is a DFT frame and by a straightforward calculation (already used in Equation (23)), respectively.

Thus, in this case, $A_{1}^{d}(u)$ is well-defined for $u : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^{d}$ by Equation (24) since its right side exists:

$$A_{1}^{d}(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} \langle u(m+k), u(k) \ast x_{nk} \rangle$$

$$= \frac{1}{N} \sum_{k=0}^{N-1} \left( \frac{d}{N} \sum_{j=0}^{N-1} \langle u(k), x_{j} \rangle x_{j} \ast x_{nk} \right)$$

$$= \frac{d}{N^{2}} \sum_{k=0}^{N-1} \sum_{j=0}^{N-1} \langle x_{j}, u(k) \rangle \langle u(m+k), x_{j+nk} \rangle.$$

Example 4.3 (STFT formulation of $A_{p}^{d}(u)$). Given $u, v : \mathbb{Z}/N\mathbb{Z} \to \mathbb{C}^{d}$, and let $X = \{x_k\}_{k=0}^{N-1} \subseteq \mathbb{C}^{d}$ be a DFT frame for $\mathbb{C}^{d}$. Suppose $\ast$ denotes pointwise (coordinatewise) multiplication with a factor of $\sqrt{d}$. Then, the frame multiplication assumptions are satisfied. Utilizing the modulation functions, $e^{j}$, defined in Definition 3.4, we compute the right side of Equation (21) to obtain

$$A_{p}^{d}(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} \tau_{-m}u(k)\overline{u(k)}e^{jn}(k).$$
Furthermore, the modulation and translation properties of the vector-valued DFT allow us to write Equation (25) as

\[ A^d_p(u)(m, n) = \frac{1}{N} \sum_{k=0}^{N-1} (\tau_m u(k)) \ast \tilde{F}^{-1}(\tau_n \hat{u})(k); \]

and, notationally, we write the right side as the generalized inner product,

\[ \frac{1}{N} \sum_{k=0}^{N-1} \{\tau_m u(k), \tilde{F}^{-1}(\tau_n \hat{u})(k)\}, \]

where \( \{u, v\} = uv \) is coordinatewise multiplication for \( u, v \in \mathbb{C}^d \). Because of the form of Equation (21), we reiterate that \( A^d_p(u) \) is compatible with the point of view of defining a vector-valued ambiguity function in the context of the STFT.

### 4.3. A generalization of the frame multiplication assumptions.

In the previous DFT examples, \( \ast \) is intrinsically related to modular addition defined on the indices of the frame elements, viz., \( x_m \ast x_n = x_{m+n} \). Suppose we are given \( X \) and \( \ast \), that satisfy the frame multiplication assumptions. It is not pre-ordained that the operation on the indices of the frame \( X \), induced by the bilinear vector multiplication, be addition mod \( N \), as is the case for DFT frames. We are interested in finding tight frames whose behavior is similar to that of DFT frames and whose index sets are Abelian groups, non-Abelian groups, or more general non-group sets and operations.

Hence, and being formulaic, we could have \( x_m \ast x_n = x_{m \bullet n} \) for some function \( \bullet : \mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/N\mathbb{Z} \rightarrow \mathbb{Z}/N\mathbb{Z} \), and, thereby, we could use non-DFT frames or even non-FUNTFs for \( \mathbb{C}^d \). Further, \( \bullet \) could be defined on index sets, that are more general than \( \mathbb{Z}/N\mathbb{Z} \). Thus, a particular case could have the setting of bilinear mappings of frames for Hilbert spaces that are indexed by groups.

For the purpose of Subsection 4.4, we continue to consider the setting of \( \mathbb{Z}/N\mathbb{Z} \) and \( \mathbb{C}^d \), but replace the first frame multiplication assumption, Equation (22), by the formula,

\[ \forall m, n \in \mathbb{Z}/N\mathbb{Z}, \quad x_m \ast x_n = x_{m \bullet n}, \]

where \( \{x_k\}_{k=0}^{N-1} \) is still a tight frame for \( \mathbb{C}^d \) and where \( \ast \) continues to be bilinear.

The formula, Equation (26), not only hints at generalization by the cross-product example of Subsection 4.4, but is the formal basis of the theory of frame multiplication in Sections 5, 6, and 7.

### 4.4. Frame multiplication assumptions for cross product frames.

Let \( \ast : \mathbb{C}^3 \times \mathbb{C}^3 \rightarrow \mathbb{C}^3 \) be the cross product on \( \mathbb{C}^3 \) and let \( \{i, j, k\} \) be the standard basis, e.g., \( i = (1, 0, 0) \in \mathbb{C}^3 \).

Therefore, we have

\[ \begin{align*}
i \ast j &= k, \quad j \ast i = -k, \quad k \ast i = j, \quad i \ast k = -j, \quad j \ast k = i, \quad k \ast j = -i, \\
i \ast i &= j \ast j = k \ast k = 0.
\end{align*} \]

The union of two tight frames and the zero vector is a tight frame, so if we let \( X = \{x_n\}_{n=0}^6 \), where \( x_0 = 0, x_1 = i, x_2 = j, x_3 = k, x_4 = -i, x_5 = -j, x_6 = -k \), then it is straightforward to check that \( X \) is a tight frame for \( \mathbb{C}^3 \) with frame bound 2.

The index operation corresponding to the frame multiplication is

\[ \bullet : \mathbb{Z}/7\mathbb{Z} \times \mathbb{Z}/7\mathbb{Z} \rightarrow \mathbb{Z}/7\mathbb{Z}, \]
where $\bullet$ is the non-Abelian, non-group operation defined by the following table:

\[
\begin{align*}
1 \bullet 2 &= 3, & 1 \bullet 3 &= 5, & 1 \bullet 4 &= 0, & 1 \bullet 5 &= 6, & 1 \bullet 6 &= 2, \\
2 \bullet 1 &= 6, & 2 \bullet 3 &= 1, & 2 \bullet 4 &= 3, & 2 \bullet 5 &= 0, & 2 \bullet 6 &= 4, \\
3 \bullet 1 &= 2, & 3 \bullet 2 &= 4, & 3 \bullet 4 &= 5, & 3 \bullet 5 &= 1, & 3 \bullet 6 &= 0, \\
4 \bullet 1 &= 7, & 4 \bullet 3 &= 8, & 4 \bullet 4 &= 9, & 4 \bullet 5 &= 10, & 4 \bullet 6 &= 11, \\
5 \bullet 1 &= 12, & 5 \bullet 2 &= 13, & 5 \bullet 3 &= 14, & 5 \bullet 4 &= 15, & 5 \bullet 5 &= 16, & 5 \bullet 6 &= 17, \\
6 \bullet 1 &= 18, & 6 \bullet 2 &= 19, & 6 \bullet 3 &= 20, & 6 \bullet 4 &= 21, & 6 \bullet 5 &= 22, & 6 \bullet 6 &= 23.
\end{align*}
\]

$n \bullet n = 0, \quad n \bullet 0 = 0 \bullet n = 0.$

We have chosen this definition of $\bullet$ for the following reasons. As we saw in Example 4.1, the three frame multiplication assumptions are essential for defining a meaningful ambiguity function. In Subsection 4.1, these assumptions were based on the formula, $x_m \ast x_n = x_{m+n}$, used in Equation (22). However, in order to generalize this point of view, we shall consider the formula, $x_m \ast x_n = x_{m\bullet n}$, as indicated in Subsection 4.3. provided the corresponding three frame multiplication assumptions can be verified. In fact, for this cross product example, it is easily checked that the frame multiplication assumptions of Equation (22) are valid when $+$ is replaced by the $\bullet$ operation defined above in (28) and the corresponding table.

Consequently, we can write the cross product as

\[
\forall u, v \in \mathbb{C}^3, \quad u \times v = u \ast v = \frac{1}{2^2} \sum_{s=1}^{6} \sum_{t=1}^{6} \langle u, x_s \rangle \langle v, x_t \rangle x_{s\bullet t}.
\]

\[
= \frac{1}{4} \sum_{n=1}^{6} \left( \sum_{j \bullet k = n} \langle u, x_j \rangle \langle v, x_k \rangle \right) x_n.
\]

One possible application of the above is that, given frame representations for $u, v \in \mathbb{C}^3$, Equation (29) allows us to compute the frame representation of $u \times v$ without the process of going back and forth between the frame representations and their standard orthogonal representations.

There are five non-isomorphic groups of order 8: the Abelian (\(\mathbb{Z}/8\mathbb{Z}, \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}\)), the dihedral, cf. Example 6.10, and the quaternion group $Q = \{\pm 1, \pm i, \pm j, \pm k\}$. The unit of $Q$ is 1, the products $ij$, etc. are the cross product as in Equation (27), and $ii = jj = kk = 1$. Clearly, $Q$ is closely related to $X = \{x_n\}_{n=0}^6$.

5. Frame multiplication

We now define the notion of a frame multiplication, that is connected with a bilinear product on the frame elements, and we analyze its properties.

**Definition 5.1 (Frame multiplication).** Let $X = \{x_j\}_{j \in J}$ be a frame for a separable Hilbert space $H$ over $\mathbb{F}$, and let $\bullet : J \times J \to J$ be a binary operation. The mapping $\bullet$ is a **frame multiplication** for $X$ or, by abuse of language, a frame multiplication for $H$, if it extends to a bilinear product $\ast$ on all of $H$, i.e., if there exists a bilinear product $\ast : H \times H \to H$ such that

\[
\forall j, k \in J, \quad x_j \ast x_k = x_{j \bullet k}.
\]

If $(G, \bullet)$ is a group, where $G = J$ and $\bullet$ is a frame multiplication for $X$, then we shall also say that $G$ **defines a frame multiplication** for $X$.

To fix ideas, we shall generally but not always deal with frame multiplication for $H = \mathbb{C}^d$. Our theory clearly extends, and many of the results are valid for infinite dimensional Hilbert spaces. Further, in light of the importance of finite dimensional spaces, that are not Hilbert spaces, e.g., in compressed sensing, we intend to extend our theory to such spaces.
Therefore, using (33) and (32), we obtain
\[ \forall (33) \]
\[ \sum \sum \]
Similarly, by multiplying on the left by \( x \), we have
\[ \sum \sum \]
Suppose \( \text{Proof.} \) \[ \sum \sum \]
for multi-sets of vectors that is independent of the index set.
Definitions and later theorems, we make no attempt to define a notion of frame multiplication not just on the elements of the frame but on the indexing of the frame. For clarity of Remark 5.2. Whether or not a particular binary operation is a frame multiplication depends not just on the elements of the frame but on the indexing of the frame. For clarity of definitions and later theorems, we make no attempt to define a notion of frame multiplication for multi-sets of vectors that is independent of the index set.
A distinction that must be kept in mind is that \( \bullet \) is a set operation on the indices of a frame while \( \ast \) is a bilinear vector product defined on all of \( \mathbb{C}^d \).
We shall investigate the interplay between bilinear vector products on \( \mathbb{C}^d \), frames for \( \mathbb{C}^d \) indexed by \( J \), and binary operations on \( J \). For example, if we fix a binary operation \( \bullet \) on \( J \), then for what sort of frames indexed by \( J \) do we obtain a frame multiplication? Conversely, if we fix a frame \( X = \{x_j\}_{j \in J} \) for \( \mathbb{C}^d \), then what sort of binary operations on \( J \) are frame multiplications for \( \mathbb{C}^d \)?
Proposition 5.3 (Binary operations for frame multiplication). Let \( X = \{x_j\}_{j \in J} \) be a frame for \( H = \mathbb{C}^d \), and let \( \bullet : J \times J \to J \) be a binary operation. Then, \( \bullet \) is a frame multiplication for \( X \) if and only if
\[ \forall \{a_i\}_{i \in J} \subseteq \mathbb{F} \text{ and } \forall j \in J, \sum_{i \in J} a_i x_i = 0 \text{ implies } \sum_{i \in J} a_i x_{i \bullet j} = 0 \text{ and } \sum_{i \in J} a_i x_{j \bullet i} = 0. \]
Proof. Suppose \( \ast \) is the bilinear product defined by \( \bullet \) and \( \{a_i\}_{i \in J} \) is a sequence of scalars. If \( \sum_{i \in J} a_i x_i = 0 \), then
\[ \sum_{i \in J} a_i x_{i \bullet j} = \sum_{i \in J} a_i (x_i \ast x_j) = \left( \sum_{i \in J} a_i x_i \right) \ast x_j = 0 \ast x_j = 0. \]
Similarly, by multiplying on the left by \( x_j \), we see that \( \sum_{i \in J} a_i x_{j \bullet i} = 0. \)
For the converse, suppose that statement (31) holds and
\[ x = \sum_i a_i x_i = \sum_i c_i x_i, \quad y = \sum_j b_j x_j = \sum_j d_j x_j \in H. \]
By (31), we have
\[ \forall j \in J, \sum_{i \in J} (a_i - c_i) x_{i \bullet j} = 0 \]
and
\[ \forall i \in J, \sum_{j \in J} (b_j - d_j) x_{i \bullet j} = 0. \]
Therefore, using (33) and (32), we obtain
\[ \sum_{i \in J} \sum_{j \in J} a_i b_j x_{i \bullet j} = \sum_{i \in J} a_i \sum_{j \in J} b_j x_{i \bullet j} = \sum_{i \in J} a_i \sum_{j \in J} d_j x_{i \bullet j} \]
Second, \( x(34) \) shall obtain a contradiction. Operations on \( C \) \( \emptyset \), \( t \) \( \text{mult}() \) \( \text{multiplications of} \) \( \text{Example 5.7} \) between. \( \text{Definition 5.6} \) (Multiplications of a frame) \( + \) \( \alpha \) \( \cdot \) \( A \) \( \text{Applying} \) \( \text{frame multiplication for} \) \( X \) \( \text{and since} \) \( \text{Proposition 5.5} \) \( A \) \( \text{if there exists an invertible linear operator} \) \( A \in L(H) \) (see Appendix 9) such that

\[
\forall j \in J, \quad Ax_j = y_j.
\]

**Proposition 5.5** (Frame multiplications for \( X \) an \( Y \)). Suppose \( X = \{x_j\}_{j \in J} \) and \( Y = \{y_j\}_{j \in J} \) are frames for \( H = \mathbb{C}^d \), and that \( X \) is similar to \( Y \). Then, a binary operation \( \bullet : J \times J \to J \) is a frame multiplication for \( X \) if and only if it is a frame multiplication for \( Y \).

**Proof.** Because \( A^{-1}y_j = x_j \) and \( A^{-1} \) is also an invertible operator, we need only prove one direction of the proposition. Suppose \( \bullet \) is a frame multiplication for \( X \) and that \( \sum_i a_i y_i = 0 \). We have

\[
0 = \sum_{i \in J} a_i y_i = \sum_{i \in J} a_i Ax_i = A \left( \sum_{i \in J} a_i x_i \right),
\]

and since \( A \) is invertible it follows that \( \sum_i a_i x_i = 0 \). By Proposition 5.3, and because \( \bullet \) is a frame multiplication for \( X \), we can assert that

\[
\forall j \in J, \quad \sum_{i \in J} a_i x_i \cdot j = 0 \quad \text{and} \quad \sum_{i \in J} a_i x_j \cdot i = 0.
\]

Applying \( A \) to both of these equations yields:

\[
\forall j \in J, \quad \sum_{i \in J} a_i y_i \cdot j = 0 \quad \text{and} \quad \sum_{i \in J} a_i y_j \cdot i = 0.
\]

Therefore, by Proposition 5.3, \( \bullet \) is a frame multiplication for \( Y \). \( \square \)

**Definition 5.6** (Multiplications of a frame). Let \( X = \{x_j\}_{j \in J} \) be a frame for \( H = \mathbb{C}^d \). The **multiplications** of \( X \) are defined and denoted by

\[\text{mult}(X) = \{\text{frame multiplications} \bullet : J \times J \to J \text{for} X\}.\]

\( \text{mult}(X) \) can be all functions (for example when \( X \) is a basis), empty, or somewhere in-between.

**Example 5.7** (The possibility for no frame multiplications). Let \( \alpha, \beta > 0 \), \( \alpha \neq \beta \), and \( \alpha + \beta < 1 \). Define \( X_{\alpha, \beta} = \{x_1 = (1,0)^t, x_2 = (0,1)^t, x_3 = (\alpha, \beta)^t\} \). Notationally, the superscript \( t \) denotes the transpose of a vector. Then, \( X_{\alpha, \beta} \) is a frame for \( \mathbb{C}^2 \) and \( \text{mult}(X_{\alpha, \beta}) = \emptyset \). A straightforward way to prove that \( \text{mult}(X_{\alpha, \beta}) = \emptyset \) is to show that there are no bilinear operations on \( \mathbb{C}^2 \) which leave \( X_{\alpha, \beta} \) invariant. Suppose \( \ast \) were such a bilinear operation. We shall obtain a contradiction.

First, we have the linear relation \( x_3 = \alpha x_1 + \beta x_2 \). Hence, by the bilinearity of \( \ast \),

\[
(34) \quad x_1 \ast x_3 = \alpha x_1 \ast x_1 + \beta x_1 \ast x_2.
\]

Second, \( \|x_1\|_2 = \|x_2\|_2 = 1 \) and \( \|x_3\|_2 < 1 \), where the inequality follows from the facts that \( \|x_3\|_2 = (\alpha^2 + \beta^2)^{1/2} \) and

\[
0 < \alpha^2 + \beta^2 = (\alpha + \beta)^2 - 2\alpha\beta < (\alpha + \beta)^2 < 1.
\]
By the properties of $\alpha$, $\beta$, and using Equation (34), we have that

\begin{equation}
\exists m, n \text{ such that } \|x_1 * x_3\|_2 = \|\alpha x_1 * x_1 + \beta x_1 * x_2\|_2
\end{equation}

\begin{equation*}
= \|\alpha x_m + \beta x_n\|_2 \leq \alpha \|x_m\|_2 + \beta \|x_n\|_2 < 1.
\end{equation*}

Thus, since $*$ leaves $X_{\alpha,\beta}$ invariant, we obtain that $x_1 * x_3 = x_3$ by (35). Furthermore, substituting $x_3$ for $x_1 * x_3$ in Equation (34) and using the assumption that $\alpha \neq \beta$, yield $x_1 * x_1 = x_1$ and $x_1 * x_2 = x_2$. Performing the analogous calculation on $x_3 * x_2$, in place of $x_1 * x_3$ above, shows that $x_2 * x_2 = x_2$ and $x_1 * x_2 = x_1$, the desired contradiction.

**Figure 1.** The frame $X_{\alpha,\beta}$ from Example 5.7 for $\alpha = 1/2$ and $\beta = 1/4$. This frame has no frame multiplications.

Of particular interest, Proposition 5.5 tells us that the canonical dual frame $\{S^{-1}x_j\}_{j \in J}$ and the canonical tight frame $\{S^{-1/2}x_j\}_{j \in J}$ share the same frame multiplications as the original frame $X$. Because of this, we shall focus our attention on tight frames. An invertible element $V \in \mathcal{L}(H)$ mapping an $A$-tight frame $X = \{x_j\}$ (frame constant $A$) to an $A'$-tight frame $Y = \{y_j\}$, as in Proposition 5.5, is a positive multiple of some $U \in \mathcal{U}(H)$, the space of unitary operators on $H$, see Appendix 9. Indeed, we have

\begin{equation*}
A \|V^*x\|^2 = \sum_{j \in J} |\langle V^*x, x_j \rangle|^2 = \sum_{j \in J} |\langle x, Vx_j \rangle|^2 = \sum_{j \in J} |\langle x, y_j \rangle|^2 = A' \|x\|^2.
\end{equation*}

This leads us to a notion of equivalence for tight frames that sounds stronger than similarity but is actually just the restriction of similarity to the class of tight frames.

**Definition 5.8** (Equivalence of tight frames). Tight frames $X = \{x_j\}_{j \in J}$ and $Y = \{y_j\}_{j \in J}$ for a separable Hilbert space $H$ are unitarily equivalent if there is $U \in \mathcal{U}(H)$ and a positive constant $c$ such that

\begin{equation*}
\forall j \in J, \quad x_j = cUy_j.
\end{equation*}

Whenever we speak of equivalence classes for tight frames we shall mean under unitary equivalence. For finite frames unitary equivalence can be stated in terms of Gramians:

**Proposition 5.9** (Unitary equivalence in terms of Gramians, [120]). Let $H = \mathbb{C}^d$ and let $X = (x_1, \ldots, x_N)$ and $Y = (y_1, \ldots, y_N)$ be sequences of vectors. Suppose $\text{span}(X) = H$, and
so $X$ is a frame for $H$. There exists $U \in U(H)$ such that $Ux_i = y_i$, for every $i = 1, \ldots, n$, if and only if
\[ \forall i, j \in \{1, \ldots, N\} \quad \langle x_i, x_j \rangle = \langle y_i, y_j \rangle, \]
i.e., the Gram matrices of $X$ and $Y$ are equal.

Thus, from Proposition 5.9, tight frames $X$ and $Y$ are unitarily equivalent if and only if one of their Gramians is a scaled version of the other. In the case where both $X$ and $Y$ are equivalent Parseval frames their Gramians are equal.

We are using Han and Larson’s [69] definition of similarity and unitary equivalence. In particular, the ordering of the frame, and not just the unordered set of frame elements, is important. This choice is in concert with the way in which we have defined frame multiplication, i.e., with a fixed index for our frame. Also, we have made no attempt to define equivalence for frames indexed by different sets. This can be done, and results can then proven about the correspondence of frame multiplications between similar or equivalent frames under this new definition. However, allowing frames with two different index sets of the same cardinality to be considered similar only obfuscates our results.

**Theorem 5.10** (Multiplications of equivalent frames). Let $X = \{x_j\}_{j \in J}$ and $Y = \{y_j\}_{j \in J}$ be finite tight frames for $H = \mathbb{C}^d$. If $X$ is unitarily equivalent to $Y$, then $\text{mult}(X) = \text{mult}(Y)$.

**Proof.** Since $X$ and $Y$ are unitarily equivalent they are similar. Therefore, by Lemma 5.5, $\bullet : J \times J \rightarrow J$ defines a frame multiplication on $X$ if and only if it defines a frame multiplication on $Y$, that is, $\text{mult}(X) = \text{mult}(Y)$. \hfill $\square$

The converse of Theorem 5.10 is not valid. The multiplications of a tight frame provide a coarser equivalence relation than unitary equivalence. In fact, as Example 5.11 demonstrates, we may have uncountably many equivalence classes of tight frames, that have the same multiplications.

**Example 5.11** (Equivalence and an empty set of frame multiplications). Let $\{\alpha_j\}_{j=1}^2$ and $\{\beta_j\}_{j=1}^2$ be real numbers such that $\alpha_1 > \beta_1 > \alpha_2 > \beta_2 > 0$, $\alpha_1 + \beta_1 < 1$, and $\alpha_2 + \beta_2 < 1$. Define $X_{\alpha_1,\beta_1}$ and $X_{\alpha_2,\beta_2}$ as in Example 5.7. Then $\text{mult}(X_{\alpha_1,\beta_1}) = \text{mult}(X_{\alpha_2,\beta_2}) = \emptyset$. It can be easily shown, by checking the six cases of where to map $(1,0)^t$ and $(0,1)^t$, that there is no invertible operator $A$ such that $AX_{\alpha_1,\beta_1} = X_{\alpha_2,\beta_2}$ as sets. Therefore, there are no $c > 0$ and $U \in U(\mathbb{R}^2)$ such that $cU$ maps between the canonical tight frames $S_1^{-1/2}X_{\alpha_1,\beta_1}$ and $S_2^{-1/2}X_{\alpha_2,\beta_2}$ (for any reordering of the elements) and $S_1^{-1/2}X_{\alpha_1,\beta_1}$ and $S_2^{-1/2}F_{\alpha_2,\beta_2}$, are not unitarily equivalent. Hence, there are uncountably many equivalence classes of tight frames, that have the same empty set of frame multiplications.

In contrast to Example 5.11, we shall see in Section 7 that if a tight frame has a particular frame multiplication in terms of a group operation, then it belongs to one of only finitely many equivalence classes of tight frames, that share the same group operation as a frame multiplication. With this goal, we close this subsection with a characterization of bases in terms of their multiplications, once we exclude the degenerate one case where one can have a frame consisting of a single repeated vector).

**Proposition 5.12** (Bases and frame multiplications). Let $X = \{x_j\}_{j \in J}$ be a finite frame for $H = \mathbb{C}^d$, and suppose $d > 1$. If $\text{mult}(X) = \{\text{all functions} \bullet : J \times J \rightarrow J\}$, then $X$ is a basis for $H$. If, in addition, $X$ is a tight, respectively, Parseval frame for $H$, then $X$ is an orthogonal, respectively, orthonormal basis for $H$. 

Proof. Suppose that \( \sum_i a_i x_i = 0, \) \( j_0 \in J, \) and \( x_{j_1}, x_{j_2} \in X \) are linearly independent. Let \( \bullet : J \times J \to J \) be the function sending all products to \( j_2 \) except that \( \forall j \in J, \ j_0 \bullet j = j_1. \)

By assumption, \( \bullet \in \text{multi}(X). \) Therefore, by Proposition 5.3, we have

\[
\forall j \in J, \quad 0 = \sum_{i \in J} a_i x_{i \bullet j} = a_{j_0} x_{j_1} + \sum_{i \neq j_0} a_i x_{j_2}.
\]

Since \( x_{j_1} \) and \( x_{j_2} \) are linearly independent, \( a_{j_0} = 0, \) and since \( j_0 \) was arbitrary, \( X \) is a linearly independent set. The last statement of the proposition follows from the elementary fact that a basis, that satisfies Parseval’s identity or a scaled version of it, is an orthogonal set. \( \square \)

6. Harmonic frames and group frames

6.1. Harmonic frames. The central part of our theory in Section 7 depends on the well-established setting of harmonic frames and group frames. We review that material here. We shall see that harmonic frames are group frames.

These are two of several related classes of frames and codes, including Grassmannian frames, that have been the object of recent and intense study. Bölcskei and Eldar [28] (2003) define geometrically uniform frames as the orbit of a generating vector under an Abelian group of unitary matrices. A signal space code was called geometrically uniform by Forney [56] (1991) or a group code by Slepian [107] (1968) if its symmetry group (a group of isometries) acts transitively. Harmonic frames are projections of the rows or columns of the character table (DFT matrix) of an Abelian group. See Definition 6.1 for a precise definition of character table and harmonic frame. Zimmermann [132] and Pfander [unpublished] independently introduced and provided substantial properties of harmonic frames at Bommerholz in 1999.

It is well known that the rows and columns of the character table of an Abelian group are orthogonal. This fact combined with the direction of Naimark’s theorem, Theorem 2.7, asserting that the orthogonal projection of an orthogonal basis is a tight frame, motivates considering the class of equal-norm frames \( X \) of \( N \) vectors for a \( d \)-dimensional Hilbert space \( H \) that arise from the character table of an Abelian group, i.e., equal norm frames given by the columns of a submatrix obtained by taking \( d \) rows of the character table of an Abelian group of order \( N. \)

Definition 6.1 (Harmonic frame for an Abelian group). Let \((G, \bullet) = \{g_1, \ldots, g_N\}\) be a finite Abelian group with dual group \( \{\gamma_1, \ldots, \gamma_N\}. \) The \( N \times N \) matrix with \((j, k)\) entry \( \gamma_k(g_j) \) is the character table of \( G. \) Let \( K \subseteq \{1, \ldots, N\}, \) where \(|K| = d \leq N, \) and with columns indexed by \( k_1, \ldots, k_d. \) Let \( U \in U(C^d). \) The harmonic frame \( X = X_{G,K,U} \) for \( C^d \) is

\[
X = \{U(\gamma_{k_1}(g_j), \ldots, \gamma_{k_d}(g_j)) : j = 1, \ldots, N\}.
\]

Given \( G, K, \) and \( U = I. \) Then, \( X \) is the DFT - FUNTF on \( G \) for \( C^d. \) In this case, if \( G = \mathbb{Z}/NZ, \) then \( X \) is the usual DFT - FUNTF for \( C^d. \)

A fundamental characterization of harmonic frames is due to Vale and Waldron [120] (2005); and they proved that harmonic frames and geometrically uniform tight frames are equivalent, e.g., [125], pages 247–248, and can be characterized by their Gramian. The intricate evaluation of the number of harmonic frames of prime order is due to Hirn [77] (2010).
6.2. Group frames. We begin with the first definition of a group frame from Han [66] (1997), where the associated representation \( \pi \) is called a frame representation, also see [57, 67–70, 122, 125].

**Definition 6.2** (Group frame – Han). Let \((G, \bullet)\) be a finite group. A finite frame \(X\) for \(H = \mathbb{C}^d\) is a group frame if there exists \(\pi : G \to \mathcal{U}(H)\), a unitary representation of \(G\), and \(x \in H\) such that

\[
X = \{\pi(g)x\}_{g \in G}.
\]

If \(X\) is a group frame, then \(X\) is generated by the orbit of any one of its elements under the action of \(G\), and if \(X\) contains \(N\) unique vectors, then each element of \(X\) is repeated \(|G|/N\) times. If \(e\) is the group identity, then we fix an “identity” element \(x_e\) of \(X\), and write \(X = \{x_g\}_{g \in G}\), where \(x_g = \pi(g)x_e\). From this we see that group frames are frames for which there exists an indexing by the group \(G\) such that

\[
\pi(g)x_h = \pi(g)\pi(h)x_e = \pi(g \bullet h)x_e = x_{gh}.
\]

This leads to a second, essentially equivalent, definition of a group frame for a frame already indexed by \(G\). This is the definition used by Vale and Waldron in [121].

**Definition 6.3** (Group frame – Vale and Waldron). Let \((G, \bullet)\) be a finite group, and let \(H = \mathbb{C}^d\). A finite tight frame \(X = \{x_g\}_{g \in G}\) for \(H\) is a group frame if there exists

\[
\pi : G \to \mathcal{U}(H),
\]

a unitary representation of \(G\), such that

\[
\forall g, h \in G, \quad \pi(g)x_h = x_{gh}.
\]

**Example 6.4** (Comparison of definitions of group frames). The difference between Definitions 6.2 and 6.3 is that in Definition 6.3 we begin with a frame as a sequence indexed by \(G\), and then ask whether a particular type of representation exists. In the first definition we began with only a multi-set of vectors and asked whether an indexing exists such that the second definition holds. For example, let \(G = \mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}, +\) and consider the frame \(X = \{x_0 = 1, x_1 = -1, x_2 = i, x_3 = -i\}\) for \(\mathbb{C}\). \(X\) would be a group frame under Definition 6.2, because there are two one-dimensional representations of \(G\) that generate \(X\). This is clear from the Fourier matrix of \(\mathbb{Z}/4\mathbb{Z}\). However, it would not qualify as a group frame under Definition 6.3, because the representation \(\pi\) would have to satisfy \(\pi(1)x_0 = x_1\), i.e., \(\pi(1)1 = -1\). There is one one-dimensional representation of \(\mathbb{Z}/4\mathbb{Z}\) which satisfies this, but it does not generate \(X\). Indeed, it is defined by \(\pi(0) = 1, \pi(1) = -1, \pi(2) = 1, \pi(3) = -1\).

In keeping with our view that a frame is a sequence with a fixed index set, we shall use the second definition.

**Remark 6.5.** From Definitions 6.1 and 6.3, we see that harmonic frames are group frames.

Vale and Waldron noted in [121] that if \(X = \{x_g\}_{g \in G}\) is a group frame, then its Gramian matrix \((G_{g,h}) = (\langle x_h, x_g \rangle)\) has a special form:

\[
\langle x_h, x_g \rangle = \langle \pi(h)x_g, \pi(g)x_g \rangle = \langle x_g, \pi(h^{-1} \bullet g)x_g \rangle,
\]

i.e., the \(g-h\)-entry is a function of \(h^{-1} \bullet g\).
Definition 6.6 (G-matrix). Let $G$ be a finite group. A matrix $A = (a_{g,h})_{g,h \in G}$ is called a G-matrix if there exists a function $\nu : G \to \mathbb{C}$ such that 

$$\forall g, h \in G, \quad a_{g,h} = \nu(h^{-1} \cdot g).$$

Vale and Waldron [121] were then able to prove essentially the following theorem using an argument that hints at a connection to frame multiplication. We include a version of their proof and highlight the connections to our theory.

Theorem 6.7 (Group frames and G-matrices). Let $G$ be a finite group. A frame $X = \{x_g\}_{g \in G}$ for $H = \mathbb{C}^d$ is a group frame if and only if its Gramian is a G-matrix.

Proof. If $X$ is a group frame, then Equation (36) implies its Gramian is the G-matrix defined by $\nu(g) = \langle x_e, \pi(g)x_e \rangle$.

For the converse, suppose the Gramian of $X$ is a G-matrix. Let $S$ be the frame operator, and let $\tilde{x}_g = S^{-1}x_g$ be the canonical dual frame elements. Each $x \in H$ has the frame decomposition

$$x = \sum_{h \in G} \langle x, \tilde{x}_h \rangle \tilde{x}_h. \quad (37)$$

For each $g \in G$, define a linear operator $U_g : H \to H$ by

$$\forall x \in H, \quad U_g(x) = \sum_{h \in G} \langle x, \tilde{x}_h \rangle \tilde{x}_{gh}. \quad (38)$$

Since the Gramian of $X$ is a G-matrix, we have

$$\forall g, h, k \in G, \quad \langle x_{gh}, x_{gk} \rangle = \nu((g \cdot h)^{-1}g \cdot k) = \nu(h^{-1} \cdot k) = \langle x_h, x_k \rangle. \quad \text{The following calculation shows that } U_g \text{ is unitary, and the calculation itself follows from (37) and (38)}.$$ 

Also, for every $h, k \in G$, we compute

$$\langle U_g(x_h) - x_{gh}, x_{gk} \rangle = \langle U_g(x_h), x_{gk} \rangle - \langle x_{gh}, x_{gk} \rangle = \langle \sum_{m \in G} \langle x_h, \tilde{x}_m \rangle x_{gm}, x_{gk} \rangle - \langle x_{gh}, x_{gk} \rangle = \sum_{m \in G} \langle x_h, \tilde{x}_m \rangle \langle x_m, x_k \rangle - \langle x_{gh}, x_{gk} \rangle = \sum_{m \in G} \langle x_h, \tilde{x}_m \rangle x_m, x_k \rangle - \langle x_h, x_k \rangle = \langle \sum_{m \in G} \langle x_h, \tilde{x}_m \rangle x_m, x_k \rangle - \langle x_h, x_k \rangle - \langle x, x_k \rangle = 0.$$ 

Letting $k$ vary over all of $G$, it follows that $U_g(x_h) = x_{gh}$. This implies that $\pi : g \mapsto U_g$ is a unitary representation, since

$$\forall g_1, g_2, h \in G, \quad U_{g_1g_2}x_h = x_{g_1g_2h} = U_{g_1}x_{g_2h} = U_{g_1}U_{g_2}x_h.$$
and since \( \{x_h\}_{h \in G} \) spans \( H \). Hence, \( \pi \) is a unitary representation of \( G \) for which \( \pi(g)x_h = x_{g \bullet h} \), i.e., \( X \) is a group frame for \( H \).

Remark 6.8. The operators \( U_g, g \in G \), defined in the proof of Theorem 6.7 are essentially frame multiplication on the left by \( x_g \), but there may not exist a bilinear product on all of \( \mathbb{C}^d \) which agrees with or properly joins the sequence \( \{U_g\}_{g \in G} \). We shall prove in Proposition 7.1 that when these operators do arise from a frame multiplication defined by \( G \), then they are unitary when the Gramian is a G-matrix. In fact, we shall see in Section 7 that, if \( G \) is an Abelian group and if the Gramian of \( X = \{x_g\}_{g \in G} \) is a G-matrix, or by Theorem 6.7 if \( X \) is a group frame for \( \mathbb{C}^d \), then \( G \) defines a frame multiplication for \( X \).

Example 6.9 (Cyclic G-matrices are circulant). If \( G \) a cyclic group, a G-matrix is a circulant matrix. To illustrate this, we consider \( G = \mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}, + \) with the natural ordering. Then all G-matrices, corresponding to this choice of \( G \), are of the form

\[
\begin{pmatrix}
\nu(0) & \nu(3) & \nu(2) & \nu(1) \\
\nu(1) & \nu(0) & \nu(3) & \nu(2) \\
\nu(2) & \nu(1) & \nu(0) & \nu(3) \\
\nu(3) & \nu(2) & \nu(1) & \nu(0)
\end{pmatrix}
\]

for some \( \nu : G \to \mathbb{C} \), and this is a 4 \( \times \) 4 circulant matrix.

Example 6.10 (The dihedral group). For a non-circulant example of a G-matrix, let \( G = D_3 \), the dihedral group of order 6. If we use the presentation,

\[D_3 = \langle r, s : r^3 = e, s^2 = e, rs = sr^2 \rangle,\]

and order the elements \( e, r, r^2, s, sr, sr^2 \), then every G-matrix has the form

\[
\begin{pmatrix}
e & r & r^2 & s & sr & sr^2 \\
e & \nu(e) & \nu(r^2) & \nu(r) & \nu(s) & \nu(sr) & \nu(sr^2) \\
r & \nu(r) & \nu(e) & \nu(r^2) & \nu(sr) & \nu(sr^2) & \nu(s) \\
r^2 & \nu(r^2) & \nu(r) & \nu(e) & \nu(sr^2) & \nu(s) & \nu(sr) \\
s & \nu(s) & \nu(sr) & \nu(sr^2) & \nu(e) & \nu(r^2) & \nu(r) \\
sr & \nu(sr) & \nu(sr^2) & \nu(s) & \nu(r) & \nu(e) & \nu(r^2) \\
sr^2 & \nu(sr^2) & \nu(s) & \nu(sr) & \nu(r^2) & \nu(r) & \nu(e)
\end{pmatrix}
\]

for some \( \nu : D_3 \to \mathbb{C} \).

Example 6.11 (Group and Grassmannian frames – perspective). a. (ETFs) In its most down to earth form, a finite tight frame \( X \) is a group frame for \( \mathbb{C}^d \) if it is the orbit of an element \( x \in \mathbb{C}^d \) under the linear action of some finite group \( G \) of linear transformations. As noted in Remark 6.5, harmonic frames are an example,

With regard to our goals of Subsection 1.2, we say that a FUNTF \( X = \{x_j\}_{j=1}^N \) for \( \mathbb{C}^d \) is an equiangular tight frame (ETF) for \( \mathbb{C}^d \) if

\[\exists \alpha \geq 0 \quad \text{such that} \quad \forall j \neq k, \quad |\langle x_j, x_k \rangle| = \alpha,\]

see Remark 2.6, where it was noted that equiangular Parseval frames (tight and frame constant \( A = 1 \)) are not unit norm. It is well known and elementary to show that for any \( d \geq 1 \) the simplex consisting of \( N = d + 1 \) elements is an ETF and that such ETFs are group frames.
On the other hand, if \( N > d^2 \), then there is no ETF for \( \mathbb{C}^d \) consisting of \( N \) elements; and these values of \( N \) can be viewed as a natural regime for the Grassmannian frames defined in part c. Further, if \( N < d^2 \), then there are known cases for which there are no ETFs, e.g., \( d = 3, N = 8 \) [115]. Determining compatible values of \( d, N \) for which there are ETFs is a subtle, unresolved, and highly motivated problem, see, e.g., [51–53,125].

b. (ETFs and the Welch bound) The coherence or maximum correlation \( \mu(X) \) of a set \( X = \{x_j\}_{j=1}^N \subseteq \mathbb{C}^d \) of unit norm elements is defined as

\[
\mu(X) = \max_{j \neq k} |\langle x_j, x_k \rangle|.
\]

Welch (1974) [126] proved the fundamental inequality,

\[
\mu(X) \geq \sqrt{\frac{N - d}{d(N - 1)}},
\]

that itself is important in understanding the behavior of the narrow band ambiguity function defined in Subsection 1.2, see [10,74]. In the case that \( X \) is a FUNTF for \( \mathbb{C}^d \), then equality holds in (40) if and only if \( X \) is an ETF with constant \( \alpha = \sqrt{\frac{N - d}{d(N - 1)}} \), see [112], Theorem 2.3, as well as [22], Theorem IV.2 (Theorem 3) for a modest but useful generalization. Because of the importance of Gabor frames in this topic, we note that if \( N = d^2 \), then \( \alpha = \sqrt{\frac{1}{d+1}} \).

c. (Grassmannian frames) If an ETF does not exist for a given \( N \geq d+2 \), then a reasonable substitute is to consider \((N,d)\)-Grassmannian frames. Grassmannian frames were mentioned in Subsection 2.2 and at the beginning of Subsection 6.1. Let \( X = \{x_j\}_{j=1}^N \subseteq \mathbb{C}^d \) be a set of unit norm elements. \( X \) is an \((N,d)\)-Grassmannian frame for \( \mathbb{C}^d \) if it is a FUNTF and if

\[
\mu(X) = \inf_{Y} \mu(Y),
\]

where the infimum is taken over all FUNTFs \( Y \) for \( \mathbb{C}^d \) consisting of \( N \) elements. A compactness argument shows that \((N,d)\)-Grassmannian frames exist, see [22], Appendix. Also, ETFs are a subclass of Grassmannian frames, see [27, 124]. Further, as noted in [112], Grassmannian frames have significant applicability, including spherical codes and designs, packet based communication systems such as the internet, and geometrically uniform codes in information theory, and these last are essentially group frames [56] (1991), cf. [28].

One of the major mathematical challenges is to construct Grassmannian frames. see [22,125].

d. (Zauner’s conjecture) Zauner’s conjecture is that for any dimension \( d \geq 1 \) there is a FUNTF \( X = \{x_j : j = 1, \ldots, d^2\} \) for \( \mathbb{C}^d \) such that

\[
\forall j \neq k, \quad |\langle x_j, x_k \rangle| = \frac{\sqrt{1}}{d+1}.
\]

The problem can be restated by asking if for each \( d \geq 1 \) there are \((d^2, d)\)-Grassmannian frames that achieve equality with the Welch bound. This is an open problem in quantum information theory, and the conjecture by Zauner [131] was motivated by issues dealing with quantum measurement, cf. [102]. There are solutions for some values of \( d \), and solutions are referred to as symmetric, informationally complete, positive operator valued measures (SIC-POVMs). POVMs not only arise in quantum measurement and detection, e.g., [21], Definition A.1, but also draw on issues dealing with coherent states [2]. Further, they have a mathematical foundation in the area of vector-valued measures since they typically are functions defined
on a Borel algebra with range $\mathcal{L}(H)$, noting that $\mathcal{L}(H)$ is a non-commutative $\ast$-Banach algebra with unit, see Subsection 9.1. In this regard and by comparison, in Example 3.12 we could let $V$ be the commutative Banach algebra of bounded Radon measures on a locally compact Abelian group. A major recent contribution to Zauner’s conjecture is [4].

Zauner’s conjecture is also related to frame potential energy in the following way. In [17] FUNTFs were characterized as the minimizers of the $\ell^2$- frame potential energy functional motivated by Coulomb’s law. The $\ell^p$-version, merely defined in [22], was developed deeply by Ehler and Okoudjou, see [45, 46]. The main theorem in [17] proves the existence of so-called Welch bound equality (WBE) sequences used for code-division multiple-access (CDMA) systems in communications, see [91, 124]. In fact, the essential inequality asserted in the WBE setting of Massey and Mittelholzer [91] is an $\ell^2$-version of the $\ell^\infty$ inequality (40); and the relevant equations in [91] are (3.4) – (3.6). With this backdrop, there is a compelling case relating solutions of Zauner’s conjecture, as well as Grassmannians, in terms of minimizers of all $\ell^p$-frame potentials, see [94].

e. (CAZAC sequences) Given a function $u : \mathbb{Z}/d\mathbb{Z} \rightarrow \mathbb{C}$. For any such $u$ we can define a Gabor FUNTF $U = \{u_j : j = 1, \ldots, d^2\}$, where each $u_j$ consists of translates and modulations of $u$. e.g., see [97].

The discrete periodic ambiguity function of $u$ was defined by (2) in Subsection 1.2. In the notation of this example, that formula becomes:

$$\forall (m, n) \in \mathbb{Z}/d\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}, \quad A(u)(m, n) = \frac{1}{d} \sum_{k=0}^{d-1} u(m+k) \overline{u(k)} e^{-2\pi i kn/d}.$$  

The function $u$ is a constant amplitude 0-autocorrelation (CAZAC) sequence if

$$\forall m \in \mathbb{Z}/d\mathbb{Z}, \quad |u(m)| = 1, \quad (CA)$$

and

$$\forall m \in \mathbb{Z}/d\mathbb{Z} \setminus \{0\}, \quad \frac{1}{d} \sum_{k=0}^{d-1} u(m+k) \overline{u(k)} = 0. \quad (ZAC).$$  

A recent survey on the theory and applicability of CAZAC sequences is [11]. The construction of all CAZAC sequences remains a tantalizing and applicable venture.

A fundamental fact is the following theorem [10], Theorem 3.8. Let $d = p$ be prime. There are explicit CAZAC sequences $u : \mathbb{Z}/p\mathbb{Z} \rightarrow \mathbb{C}$ (due to Björck) with the property that if $(m, n) \in (\mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}) \setminus \{(0, 0)\}$, then

$$|A(u)(m, n)| \leq \frac{2}{\sqrt{p}} + \begin{cases} \frac{4}{p} & \text{if } p \equiv 1 \ (\text{mod } 4) \\ \frac{4}{p^{7/2}} & \text{if } p \equiv 3 \ (\text{mod } 4). \end{cases}$$

In particular, $|A(u)(m, n)| \leq 3/\sqrt{p}$.

This implies that the coherence $\mu(U)$ of $U$ satisfies the inequalities,

$$(41) \quad \frac{1}{\sqrt{p}+1} \leq \mu(U) \leq \frac{3}{\sqrt{p}},$$

even though $|A(u)(m, n)|$ can have significantly smaller values than $3/\sqrt{p}$ for various $(m, n)$. This latter property hints at the deeper applicability of CAZAC sequences such as the Björck sequence.

Because of the 0-autocorrelation property, CAZAC sequences are the opposite of what candidates for Zauner’s conjecture should be. On the other hand, the inequality (41) gives
perspective with regard to Zauner’s conjecture. Further, these CAZAC sequences are an essential component of the background and goals dealing with phase-coded waveforms that were the driving force leading to the role of group frames in our vector-valued theory, see Subsections 1.1 and 1.2.

7. FRAME MULTIPLICATION FOR GROUP FRAMES

7.1. Frame multiplication defined by groups. We now deal with the special case of frame multiplications defined by binary operations $\bullet : J \times J \to J$ that are group operations, i.e., when $J = G$ is a group and $\bullet$ is the group operation. Recall that if $X = \{x_g\}_{g \in G}$ is a frame for $H = \mathbb{C}^d$ and the group operation of $G$ is a frame multiplication for $X$, then we say that $G$ defines a frame multiplication for $X$.

We state and prove Proposition 7.1 in some generality to illustrate the basic idea and its breadth. We use it to prove Theorem 7.3.

Proposition 7.1 (Frame multiplications and canonical unitary operators). Let $(G, \bullet)$ be a countable group, and let $H$ be a complex separable Hilbert space. Assume $X = \{x_g\}_{g \in G}$ is a tight frame for $H$. If $G$ defines a frame multiplication for $X$ with continuous extension $\ast$ to all of $H$, then the functions $L_g : H \to H$, defined by

$$L_g(x) = x \ast x,$$

and $R_g : H \to H$, defined by

$$R_g(x) = x \ast x_g,$$

are unitary linear operators for every $g \in G$.

Proof. Let $x \in H$, $g \in G$, and $A$ be the frame constant for $X$. Linearity and continuity of $L_g$ follow from the bilinearity and continuity of $\ast$. To show that $L_g$ is unitary, we first compute

$$A \|L_g^\ast(x)\|^2 = \sum_{h \in G} |\langle L_g^\ast(x), x_h \rangle|^2 = \sum_{h \in G} |\langle x, L_g(x_h) \rangle|^2$$

$$= \sum_{h \in G} |\langle x, x_g \ast x_h \rangle|^2 = \sum_{h \in G} |\langle x, x_{gh} \rangle|^2 = \sum_{h \in G} |\langle x, x_h \rangle|^2 = A \|x\|^2.$$

Therefore, $L_g^\ast$ is an isometry. If $H = \mathbb{C}^d$, then this is equivalent to $L_g^\ast$ and $L_g$ being unitary.

For the infinite dimensional case, we also need that $L_g$ is an isometry, this being one of the equivalent characterizations of unitary operators.

To prove that $L_g$ is an isometry, we first show it is invertible and that $L_g^{-1} = L_{g^{-1}}$. To this end, we begin by defining

$$D = \left\{ \sum_h a_h x_h : |\{a_h : a_h \neq 0\}| < \infty \right\},$$

i.e., $D$ is the set of all finite linear combinations of frame elements from $X$. It follows from the frame reconstruction formula that $D$ is dense in $H$. Now, for any $g \in G$, $L_g$ maps $D$ onto $D$, and for every $x = \sum_{h \in G} a_h x_h \in D$, we compute

$$L_g^{-1} L_g(x) = L_g^{-1} L_g \left( \sum_{h \in G} a_h x_h \right).$$
and of the fact that the DFT diagonalizes circulant matrices is that the columns of $X$ are in the nullspace of the circulant matrix $A$. A consequence of this and of the fact that the DFT diagonalizes circulant matrices is that the columns of $X$ are equalities.

In short, $L^{-1} \cdot L$ is linear, bounded, and is the identity on a dense subspace of $H$. Therefore, $L^{-1} \cdot L$ is the identity on all of $H$.

We can now verify that $L_g$ is an isometry. From general operator theory, we have the equalities

$$\|L_g^{-1}\|_{op} = \|L_g^{-1}\|_{op} = \|L_g^*\|_{op} = 1,$$

and

$$\|L_g\|_{op} = \|L_g^*\|_{op} = 1.$$

Invoking these and the definition of the operator norm, we obtain

$$\|L_g(x)\| \leq \|x\| \quad \text{and} \quad \|x\| = \|L_g^{-1}L_g(x)\| \leq \|L_g^{-1}\|_{op} \|L_g(x)\| = \|L_g(x)\|.$$

Therefore, $\|L_g(x)\| = \|x\|$, the desired isometry.

The same calculations prove that $R_g$ is unitary.

In contrast to the generality of Proposition 7.1, we next give a specific example providing direction that led to our main results in Subsection 7.2.

**Example 7.2** (Frame multiplication and the DFT). Let $X = \{x_k\}_{k=0}^{N-1} \subseteq \mathbb{C}^d$ be a linearly dependent frame for $\mathbb{C}^d$, and so $N > d$. Suppose $\ast : \mathbb{C}^d \times \mathbb{C}^d \rightarrow \mathbb{C}^d$ is a bilinear product such that $x_m \ast x_n = x_{m+n}$, i.e., $\mathbb{Z}/N\mathbb{Z}$ defines a frame multiplication for $X$. By linear dependence, there exists a sequence $\{a_k\}_{k=0}^{N-1} \subseteq \mathbb{C}$ of coefficients, not all zero, such that

$$\sum_{k=0}^{N-1} a_k x_k = 0.$$

Multiplying on the left by $x_m$ and utilizing the aforementioned properties of $\ast$ yield

$$\forall m \in \mathbb{Z}/N\mathbb{Z}, \quad 0 = x_m \ast \left( \sum_{k=0}^{N-1} a_k x_k \right) = \sum_{k=0}^{N-1} a_k \left( x_m \ast x_k \right) = \sum_{k=0}^{N-1} a_k x_{m+k}. \quad (42)$$

It is convenient to rewrite (42) with the index on the coefficients varying with $m$:

$$\forall m \in \mathbb{Z}/N\mathbb{Z}, \quad \sum_{k=0}^{N-1} a_{k-m} x_k = 0. \quad (43)$$

Let $a = (a_k)_{k=0}^{N-1}$, let $A$ be the $N \times N$ circulant matrix generated by the vector $a$ and with eigenvalues $\lambda_j, j = 0, \ldots, N - 1$, and let $X$ be the $N \times d$ matrix with vectors $x_k$ as its rows. In symbols,

$$A = \begin{pmatrix} a_0 & a_1 & a_2 & \cdots & a_{N-1} \\ a_{N-1} & a_0 & a_1 & \cdots & a_{N-2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_1 & a_2 & a_3 & \cdots & a_0 \end{pmatrix} \quad \text{and} \quad X = \begin{pmatrix} x_0 \\ x_1 \\ \vdots \\ x_{N-1} \end{pmatrix}.$$

In matrix form, Equation (43) is

$$AX = 0.$$

Thus, the columns of $X$ are in the nullspace of the circulant matrix $A$. A consequence of this and of the fact that the DFT diagonalizes circulant matrices is that the columns of $X$ are...
linear combinations of some subset of at least \( d \) (the rank of \( X \) is \( d \)) columns of the DFT matrix. Further, if \( \omega_j = e^{2\pi ij/N} \), then

\[
a_0 + a_{N-1}\omega_j + a_{N-2}\omega_j^2 + \ldots + a_1\omega_j^{N-1} = \lambda_j,
\]
is zero for at least \( d \) choices of \( j \in \{0, 1, \ldots, N-1\} \). Hence, assuming that \( \mathbb{Z}/N\mathbb{Z} \) defines a frame multiplication for a frame \( X \) for \( \mathbb{C}^d \), we obtain a condition involving the DFT.

7.2. Abelian frame multiplications.

**Theorem 7.3** (Abelian frame multiplications for group frames). Let \((G, \bullet)\) be a finite Abelian group, and assume that \( X = \{x_g\}_{g \in G} \) is a tight frame for \( H = \mathbb{C}^d \). \( G \) defines a frame multiplication for \( X \) if and only if \( X \) is a group frame.

**Proof.** i. Suppose \( G \) defines a frame multiplication for \( X \) and the bilinear product given on \( H \) is \( \ast \). For each \( g \in G \) define an operator \( U_g : H \to H \) by the formula

\[
U_g(x) = x_g \ast x.
\]

By Proposition 7.1, \( \{U_g\}_{g \in G} \) is a family of unitary operators on \( H \). Define the mapping \( \pi : g \mapsto U_g \). \( \pi \) is a unitary representation of \( G \) because

\[
U_g U_h x_k = U_g(x_h \ast x_k) = U_g(x_h \ast k) = x_g \ast x_h = x_{gh} = U_{gh} x_k,
\]

and since \( \{x_k\}_{k \in G} \) spans \( H \). Further, we have \( \pi(g)x_h = x_{gh} \), thereby proving \( X \) is a group frame.

ii. Conversely, suppose \( X = \{x_g\}_{g \in G} \) is a group frame. Then, there exists a unitary representation \( \pi \) of \( G \) such that \( \pi(g)x_h = x_{gh} \). It follows from the facts, \( \pi(g) \) is unitary and \( G \) is Abelian, that

\[
\forall g, h_1, h_2 \in G, \quad \langle x_{h_1}, x_{h_2} \rangle = \langle \pi(g)x_{h_1}, \pi(g)x_{h_2} \rangle = \langle x_{gh_1}, x_{gh_2} \rangle = \langle x_{h_1 \bullet g}, x_{h_2 \bullet g} \rangle.
\]

iii. If \( \sum_{g \in G} a_g x_g = 0 \), then for any \( j, k \in G \) we have

\[
0 = \sum_{g \in G} a_g x_g, x_j = \sum_{g \in G} a_g \langle x_g, x_j \rangle = \sum_{g \in G} a_g \langle x_{g \bullet k}, x_{j \bullet k} \rangle.
\]

Allowing \( j \) to vary over all of \( G \) shows that \( \sum_{g \in G} a_g x_{g \bullet k} = 0 \). Similarly, we can use the fact that \( \langle x_g, x_j \rangle = \langle x_{h \bullet g}, x_{h \bullet j} \rangle \) to show \( \sum_{g \in G} a_g x_{h \bullet g} = 0 \). Hence, by Proposition 5.3, \( \bullet \) is a frame multiplication for \( X \).

Theorem 7.3 can be refined in the following way. In this regard, it should be pointed out that the theory of group frames is far more extensive than that of harmonic frames, see [125].

**Theorem 7.4** (Abelian frame multiplications for harmonic frames). Let \((G, \bullet)\) be a finite Abelian group. Assume that \( X = \{x_g\}_{g \in G} \) is a tight frame for \( H = \mathbb{C}^d \). If \( G \) defines a frame multiplication for \( X \), then \( X \) is unitarily equivalent to a harmonic frame, and there exists \( U \in \mathcal{U}(\mathbb{C}^d) \) and \( c > 0 \) such that

\[
cU \left( x_g \ast x_h \right) = cU \left( x_g \right) cU \left( x_h \right),
\]

where the product on the right is vector pointwise multiplication and \( \ast \) is the frame multiplication defined by \((G, \bullet)\), i.e., \( x_g \ast x_h = x_{g \bullet h} \).
Proof. i. For each \( g \in G \) define an operator \( U_g : \mathbb{C}^d \to \mathbb{C}^d \) by the formula
\[
U_g(x) = x_g \ast x.
\]
By Theorem 7.3, \( \{U_g\}_{g \in G} \) is an Abelian group of unitary operators, that generates
\[
X = \{U_g(x_e) : g \in G\},
\]
where \( e \) is the unit of \( G \). Furthermore, since the \( U_g \) are unitary, we have
\[
\forall g \in G, \quad \|x_e\|_2 = \|U_g(x_e)\|_2 = \|x_g\|_2,
\]
which shows that \( X \) is equal-norm.

ii. For the next step we use a technique found in the proof of Theorem 5.4 of [120]. A commuting family of diagonalizable operators, such as \( \{U_g\}_{g \in G} \), is simultaneously diagonalizable, i.e., there is a unitary operator \( V \) for which
\[
\forall g \in G, \quad D_g = VU_gV^*
\]
is a diagonal matrix, see [79] Theorem 6.5.8, cf. [80] Theorem 2.5.5.

This is also a consequence of Schur’s lemma and Maschke’s theorem, see Appendix 9. Since \( \{U_g\}_{g \in G} \) is an Abelian group of operators, all the invariant subspaces are one dimensional, and so, orthogonally decomposing \( \mathbb{C}^d \) into the invariant subspaces of \( \{U_g\}_{g \in G} \), simultaneously diagonalizes the operators \( U_g \). The operators \( D_g \) are unitary, and consequently, they have diagonal entries of modulus 1.

iii. Define a new frame, \( Y \), generated by the diagonal operators \( D_g \), as
\[
Y = \{D_gy : g \in G\}, \text{ where } y = V(x_e).
\]
Since \( V^*D_gV = U_g \), we have
\[
X = \{U_g(x_e) : g \in G\} = V^*Y;
\]
or
\[
VX = Y.
\]
Let \((D_g y)_j\) be the \( j \)-th component of the vector \( D_g y \). Form the \( d \times |G| \) matrix with columns the elements of \( Y \), i.e., if we write \( G = \{g_1, \ldots, g_N\} \), then we form
\[
\begin{pmatrix}
(D_{g_1}y)_0 & \cdots & (D_{g_N}y)_0 \\
(D_{g_1}y)_1 & \cdots & (D_{g_N}y)_1 \\
\vdots & \ddots & \vdots \\
(D_{g_1}y)_{d-1} & \cdots & (D_{g_N}y)_{d-1}
\end{pmatrix}
\]  
(46)
Since \( Y \) is the image of \( X \) under \( V \), it is an equal-norm tight frame, and the synthesis operator matrix (46) has orthogonal rows of equal length. We compute the norm of row \( j \) to be
\[
\left( \sum_g |(D_g y)_j|^2 \right)^{1/2} = \sqrt{|G|} |(y)_j|.
\]
Therefore, the components of \( y \) have equal modulus, and, so, if we let \( W^* \) be the diagonal matrix with the entries of \( y \) on its diagonal, then there exists \( c > 0 \) such that \( cW^* \) is a unitary matrix.

iv. Now, we have
\[
X = \frac{1}{c} U^* \{D_g\mathbb{1} : g \in G\}, \quad \text{where } \mathbb{1} = (1, 1, \ldots, 1)^t \text{ and } U^* = cV^*W^* \text{ is unitary.}
\]
It is important to note that we have more than just the equality of sets of vectors as stated above. In fact, the $g$’s on both sides coincide under the transformation, i.e.,

$$\frac{1}{c}U^* (D_g \mathbb{1}) = V^* W^* D_g (\mathbb{1}) = V^* D_g(y)$$

$$= U_g V^*(y) = U_g(x_e) = x_g.$$ 

Thus, we have found a unitary operator $U$ and $c > 0$ such that $cUx_g = D_g \mathbb{1}$.

It remains to show that $\{D_g \mathbb{1} : g \in G\}$ is a harmonic frame and that the product $*$ behaves as claimed. Proving $\{D_g \mathbb{1} : g \in G\}$ is harmonic amounts to showing, for $j = 0, 1, \ldots, d - 1$, that the mapping,

$$\gamma_j : G \to \mathbb{C},$$

defined by

$$\gamma_j(g) = (D_g \mathbb{1})_{j} = (D_g)_{jj}$$

is a character of the group $G$. This follows since

$$\forall j = 0, \ldots, d - 1, \quad \gamma_j(gh) = (D_{gh})_{jj} = (D_g)_{jj}(D_h)_{jj} = \gamma_j(g)\gamma_j(h).$$

and $|(D_g)_{jj}| = 1$.

Finally, because $cU(x_g) = D_g \mathbb{1}$, we can compute

$$cU(x_g * x_h) = cU(x_{gh})$$

$$= D_{gh} \mathbb{1} = (D_g \mathbb{1})(D_h \mathbb{1}) = cU(x_g)cU(x_h).$$

\[\square\]

**Remark 7.5.** Strictly speaking, we could have canceled $c$ from both sides of Equation (45). We left them in place because, as we saw in the proof, $cU$ maps the tight frame $X$ to a harmonic frame. Therefore, it is made clearer what (45) means when each $c$ is in place, i.e., performing the frame multiplication defined by $G$ and then mapping to the harmonic frame is the same as first mapping to the harmonic frame and then multiplying pointwise.

In much of our discussion motivating this material, we assumed there was a bilinear product on $\mathbb{C}^d$ and a frame $X$ such that $x_m * x_n = x_{m+n}$, i.e., our underlying group was $\mathbb{Z}/NZ$. By strengthening our assumptions on $X$ to be a tight frame, we can apply Theorem 7.3 to show that $X$ is a group frame for the Abelian group $\mathbb{Z}/NZ$, and furthermore, by Theorem 7.4, $X$ is unitarily equivalent to a DFT frame, i.e., a harmonic frame with $G = \mathbb{Z}/NZ$. Therefore, we have the following corollary.

**Corollary 7.6** (Frame multiplication and DFT frames). Let $X = \{x_n\}_{n \in \mathbb{Z}/NZ} \subseteq \mathbb{C}^d$ be a tight frame for $\mathbb{C}^d$. If $\mathbb{Z}/NZ$ defines a frame multiplication for $X$, then $X$ is unitarily equivalent to a DFT frame.

**Example 7.7** ($G = \mathbb{Z}/4\mathbb{Z}$, frame multiplication, and a harmonic frame). Consider the group $G = \mathbb{Z}/4\mathbb{Z}$, and let

$$X = \left\{ x_0 = \begin{pmatrix} 1 + i \\ 1 - i \end{pmatrix}, x_1 = \begin{pmatrix} 0 \\ 2 \end{pmatrix}, x_2 = \begin{pmatrix} 1 - i \\ 1 + i \end{pmatrix}, x_3 = \begin{pmatrix} 2 \\ 0 \end{pmatrix} \right\}.$$ 

$X = \{x_g\}_{g \in \mathbb{Z}/4\mathbb{Z}}$ is a tight frame for $\mathbb{C}^2$, and the Gramian of $X$ is

$$G = \begin{pmatrix}
4 & 2 + 2i & 0 & 2 - 2i \\
2 - 2i & 4 & 2 + 2i & 0 \\
0 & 2 - 2i & 4 & 2 + 2i \\
2 + 2i & 0 & 2 - 2i & 4
\end{pmatrix}.$$
It is straightforward to check that $G$ is a $G$-matrix for $\mathbb{Z}/4\mathbb{Z}$, and therefore, by Theorems 6.7 and 7.3, $\mathbb{Z}/4\mathbb{Z}$ defines a frame multiplication for $X$. Hence, by Theorem 7.4, there exists a unitary matrix $U$ and positive constant $c$ such that $cUX$ is a harmonic frame. Indeed, if we let

$$c = \frac{1}{\sqrt{2}}, \quad U = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix},$$

then

$$Y = cUX = \left\{ y_\omega = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, y_\pi = \begin{pmatrix} 1 \\ i \end{pmatrix}, y_{\bar{\omega}} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}, y_{\bar{\pi}} = \begin{pmatrix} 1 \\ -i \end{pmatrix} \right\}$$

is a harmonic frame, and

$$\forall g, h \in \mathbb{Z}/4\mathbb{Z}, \quad cU(x_{gh}) = cU(x_g)cU(x_h).$$

8. Uncertainty Principles

8.1. Background. Uncertainty principle inequalities abound in harmonic analysis, e.g., see [8, 14, 29, 36, 38, 41–43, 47–49, 55, 63, 72, 103, 104, 109]. The classical Heisenberg uncertainty principle is deeply rooted in quantum mechanics, see [58, 73, 123, 127]. The classical mathematical uncertainty principle inequality was first stated and proved in the setting of $L^2(\mathbb{R})$ in 1924 by Norbert Wiener at a Gottingen seminar [5], also see [83]. This is Theorem 8.1.

**Theorem 8.1** (Heisenberg uncertainty principle inequality). If $f \in L^2(\mathbb{R})$ and $x_0, \gamma_0 \in \mathbb{R}$,

\begin{equation}
\| f \|_2^2 \leq 4\pi \left( \int (x - x_0)^2 |f(x)|^2 \, dx \right)^{1/2} \left( \int (\gamma - \gamma_0)^2 |\hat{f}(\gamma)|^2 \, d\gamma \right)^{1/2},
\end{equation}

and there is equality if and only if

$$f(x) = C e^{2\pi i x \gamma_0} e^{-s(x-x_0)^2},$$

for some $C \in \mathbb{C}$ and $s > 0$.

The proof of the basic inequality, (47), in Theorem 8.1 is a consequence of the following calculation for $(x_0, \gamma_0) = (0, 0)$ and for $f \in \mathcal{S}(\mathbb{R})$, the Schwartz class of infinitely differentiable rapidly decreasing functions defined on $\mathbb{R}$.

\begin{equation}
\| f \|^4_2 = \left( \int_\mathbb{R} x |f(x)|^2 \, dx \right)^2 \leq \left( \int_\mathbb{R} |x| \| f(x) \|^2 \, dx \right)^2 \leq 4 \left( \int_\mathbb{R} |xf(x)f'(x)| \, dx \right)^2 \leq 4 \|xf(x)\|_2^2 \|f'(x)\|_2^2 = 16\pi^2 \|xf(x)\|_2^2 \|\gamma \hat{f}(\gamma)\|_2^2.
\end{equation}

Integration by parts gives the first equality and the Plancherel theorem gives the second equality; the third inequality of (48) is a consequence of Hölder’s inequality, cf. the proof of (47) in Subsection 8.2. For more complete proofs, see, for example, [7, 55, 63, 127]. Integration by parts and Plancherel’s theorem can be generalized significantly by means of Hardy inequalities and weighted Fourier transform norm inequalities, respectively, to yield extensive weighted generalizations of Theorem 8.1, see [14] for a technical outline of this.
8.2. The classical uncertainty principle and self-adjoint operators. Let $A$ and $B$ be linear operators on a Hilbert space $H$. The commutator $[A, B]$ of $A$ and $B$ is defined as

$$[A, B] = AB - BA.$$ 

Let $D(A)$ denote the domain of $A$. The expectation or expected value of a self-adjoint operator $A$ in a state $x \in H$ is defined by the expression

$$E_x(A) = \langle A \rangle = \langle Ax, x \rangle;$$

and, since $A$ is self-adjoint, we have

$$\langle A^2 \rangle = \langle Ax, Ax \rangle = \|Ax\|^2.$$ 

The variance of a self-adjoint operator $A$ at $x \in D(A^2)$ is defined by the expression

$$\Delta^2_x(A) = E_x(A^2) - \{E_x(A)\}^2.$$ 

$\langle A \rangle$ and $\langle A^2 \rangle$ depend on a state $x \in H$, but traditionally $x$ is often not explicitly mentioned.

We begin with the following Hilbert space uncertainty principle inequality.

**Theorem 8.2** (A Hilbert space uncertainty principle inequality, [8], Theorem 7.2). Let $A$, $B$ be self-adjoint operators on a complex Hilbert space $H$ ($A$ and $B$ need not be continuous). If

$$x \in D(A^2) \cap D(B^2) \cap D(i[A, B])$$

and $\|x\| \leq 1$, then

$$\{E_x(i[A, B])\}^2 \leq 4 \Delta^2_x(A) \Delta^2_x(B).$$

In the same vein, and with the same dense domain of definition constraints as in Theorem 8.2, we have –

**Theorem 8.3** (A variant on a Hilbert space uncertainty principle inequality). Let $A$ and $B$ be self-adjoint operators on a Hilbert space $H$. Define the self-adjoint operators $T = AB + BA$ (the anti-commutator) and $S = -i [A, B]$. Then, for a given state $x \in H$, we have

$$\langle x, Tx \rangle^2 + \langle x, Sx \rangle^2 \leq 4 \langle A^2 \rangle \langle B^2 \rangle.$$

Equality holds in (50) if and only if there exists $z_0 \in \mathbb{C}$ such that $Ax = z_0 Bx$.

**Proof.** Applying the Cauchy-Schwarz inequality and self-adjointness of $A$ we obtain

$$\langle A^2 \rangle \langle B^2 \rangle = \|Ax\|^2 \|Bx\|^2 \geq |\langle Ax, Bx \rangle|^2 = |\langle A, ABx \rangle|^2.$$ 

By definition of $T$ and $S$, we have $AB = \frac{1}{2} T + \frac{1}{2} S$. Therefore,

$$|\langle x, ABx \rangle|^2 = \frac{1}{4} |\langle x, (T + iS)x \rangle|^2$$

$$= \frac{1}{4} \left| \langle x, Tx \rangle - i \langle x, Sx \rangle \right|^2 = \frac{1}{4} \left( \langle x, Tx \rangle^2 + \langle x, Sx \rangle^2 \right).$$

The final equality holds because $\langle x, Tx \rangle$ and $\langle x, Sx \rangle$ are real, and (50) follows from (51) and (52).

Last, equality holds if and only if we have equality in the application of Cauchy-Schwarz, and this occurs when $Ax$ and $Bx$ are linearly dependent. \qed
Example 8.4 (Comparison of Theorems 8.2 and 8.3). The uncertainty principle inequalities (49) and (50) can be compared quantitatively by substituting the definitions of expected value and variance into the inequalities themselves. As such, (49) becomes

\[(\text{Im}(BA))^2 \leq (\langle A^2 \rangle - \langle A \rangle^2) (\langle B^2 \rangle - \langle B \rangle^2),\]

and (50) becomes

\[(\text{Re}(BA))^2 - (\text{Im}(BA))^2 \leq \langle A^2 \rangle \langle B^2 \rangle.\]

Theorem 8.3 implies the more frequently used inequality for self-adjoint operators $A$ and $B$, viz.,

\[|\langle [A, B|x, x] \rangle| \leq 2 \|Ax\| \|Bx\|.\]

Indeed, dropping the anti-commutator term from the right side of (50) leaves

\[\langle x, Sx \rangle^2 = |\langle [A, B|x, x] \rangle|^2.\]

We have equality in (53) when $Ax$ and $Bx$ are linearly dependent (as above) and $\langle x, Tx \rangle = 0$, i.e., when $\langle Ax, Bx \rangle$ is completely imaginary. This weaker form of (50) is enough to prove Theorem 8.1, and thus the full content of Theorem 8.3 is usually neglected; however, we shall make use of it in Subsection 8.3.

Define the position and momentum operators respectively by

\[Qf(x) = xf(x), \quad Pf(x) = \frac{1}{2\pi i} f'(x).\]

$Q$ and $P$ are densely defined linear operators on $L^2(\mathbb{R})$. When employing Hilbert space operator inequalities, such as (50) and (53), they are valid only for $x \in H$ in the domains of all the operators in question, i.e., $A$, $B$, $AB$, and $BA$. We are now ready to prove Theorem 8.1 using the self-adjoint operator approach of this subsection, see [14] for other examples.

**Proof of Theorem 8.1.** Let $Q$ and $P$ be as defined above. Then, for $f, g \in D(Q)$, we have

\[\langle Qf, g \rangle = \int xf(x) \overline{g(x)} \, dx = \int f(x) \overline{xg(x)} \, dx = \langle f, Qg \rangle,\]

and for $f, g \in D(P)$,

\[\langle Pf, g \rangle = \frac{1}{2\pi i} \int f'(x) \overline{g(x)} \, dx = -\frac{1}{2\pi i} \int f(x) \overline{g'(x)} \, dx = \langle f, Pg \rangle.\]

Therefore $Q$ and $P$ are self-adjoint. The operators $Q - x_0$ and $P - \gamma_0$ are also self-adjoint and $[Q - x_0, P - \gamma_0] = [Q, P]$. Thus, (53) implies that for every $f$ in the domain of $Q$, $P$, $QP$, and $PQ$, e.g., $f$ a Schwartz function,

\[\frac{1}{2} |\langle [Q, P]|f, f \rangle| \leq \|(Q - x_0)f\| \|(P - \gamma_0)f\|.\]

For the commutator term we obtain

\[[Q, P]f(x) = \frac{1}{2\pi i} (xf'(x) - (f'(x) + xf'(x))) = -\frac{1}{2\pi i} f(x).\]

Combining (54) and (55) yields

\[\frac{1}{4\pi} \|f\|^2_2 \leq \|(Q - x_0)f\| \|(P - \gamma_0)f\|.\]
It is an elementary fact from Fourier analysis that \( (d/dx)\hat{f}(\gamma) = 2\pi i \hat{\gamma} \hat{f}(\gamma) \); applying this and Plancherel’s theorem to the second term yields
\[
\| (P - \gamma_0) f \| = \left( \int (\gamma - \gamma_0)^2 |\hat{f}(\gamma)|^2 d\gamma \right)^{1/2},
\]
and Heisenberg’s inequality (47) follows. \( \square \)

8.3. An uncertainty principle for the vector-valued DFT. The uncertainty principle we prove for the vector-valued DFT is an extension of an uncertainty principle inequality proved by Grünbaum for the DFT in [65]. We begin by defining two operators meant to represent the position and momentum operators defined on \( \mathbb{R} \) in Subsection 8.2.

Define
\[
P : \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \rightarrow \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z})
\]
by the formula,
\[
(56) \quad \forall m \in \mathbb{Z}/N\mathbb{Z}, \quad P(u)(m) = i(u(m + 1) - u(m - 1));
\]
and, given a fixed real valued \( q \in \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \), define
\[
Q : \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \rightarrow \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z})
\]
by the formula
\[
(57) \quad \forall m \in \mathbb{Z}/N\mathbb{Z}, \quad Q(u)(m) = q(m)u(m).
\]

**Proposition 8.5** (Position and momentum operators are self-adjoint). The operators \( P \) and \( Q \) defined by (56) and (57) are linear and self-adjoint.

**Proof.** The linearity of \( P \) and \( Q \) and self-adjointness of \( Q \) are clear. To show that \( P \) is self-adjoint, let \( u, v \in \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \). We compute
\[
\langle Pu, v \rangle = \sum_{m=0}^{N-1} \langle P(u)(m), v(m) \rangle = \sum_{m=0}^{N-1} \langle i(u(m + 1) - u(m - 1)), v(m) \rangle
\]
\[
= \sum_{m=0}^{N-1} i\langle u(m + 1), v(m) \rangle - i\langle u(m - 1), v(m) \rangle = \sum_{m=0}^{N-1} i\langle u(m), v(m - 1) \rangle - i\langle u(m), v(m + 1) \rangle
\]
\[
= \sum_{m=0}^{N-1} \langle u(m), i(v(m + 1) - v(m - 1)) \rangle = \langle u, Pv \rangle. \quad \square
\]

Define the anti-commutator \( T = QP + PQ \) and \( S = -i[Q, P] \). Because the Hilbert space \( H = \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \) is finite dimensional, \( T \) and \( S \) are linear self-adjoint operators defined on all of \( H \). Applying Theorem 8.3 gives an uncertainty principle inequality for the operators \( Q \) and \( P \):
\[
(58) \quad \forall u \in \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}), \quad \left( \langle u, Tu \rangle^2 + \langle u, Su \rangle^2 \right) \leq 4\langle Q^2 \rangle \langle P^2 \rangle.
\]
In this form, (58) does not appear to be related to the vector-valued DFT. We shall make the connection by finding appropriate expressions for each of the terms in (58), thereby yielding a form of the Heisenberg inequality for the vector-valued DFT.
The expected values of $Q$ and $P$ are
\[
\langle Q^2 \rangle = \langle Qu, Qu \rangle = \sum_{m=0}^{N-1} \langle Q(u)(m), Q(u)(m) \rangle
\]
\[
= \sum_{m=0}^{N-1} \langle q(m)u(m), q(m)u(m) \rangle = \sum_{m=0}^{N-1} \|q(m)u(m)\|_{\mathcal{E}(\mathbb{Z}/d\mathbb{Z})}^2 = \|qu\|^2
\]
and
\[
\langle P^2 \rangle = \langle Pu, Pu \rangle = \|Pu\|^2 = \|i(\tau_1 u - \tau_1 u)\|^2
\]
\[
= \|\mathcal{F}(\tau_1 u - \tau_1 u)\|^2 = \|e^1 \hat{u} - e^{-1} \hat{u}\|^2 = \|(e^1 - e^{-1}) \hat{u}\|^2.
\]
In the computation of $\langle P^2 \rangle$ we use the unitarity of the vector-valued DFT mapping $\mathcal{F}$ and the fact that $e^1$ and $e^{-1}$ are the modulation functions $e^j(m) = x_{jm}$, for a given DFT frame $\{x_k\}_{k=0}^{N-1}$ for $\mathbb{C}^d$, see Definition 3.4.

We restate these expected values:
\[\langle Q^2 \rangle = \|qu\|^2 \text{ and } \langle P^2 \rangle = \|(e^1 - e^{-1}) \hat{u}\|^2.\]  

We now seek expressions for the terms $\langle u, Tu \rangle^2$ and $\langle u, Su \rangle^2$. Computing the commutator and anti-commutator of $Q$ and $P$ gives
\[i Su(m) = [Q, P]u(m) = i(q(m) - q(m + 1))u(m + 1) - i(q(m) - q(m - 1))u(m - 1)\]
and
\[Tu(m) = (QP + PQ)u(m) = i(q(m) + q(m + 1))u(m + 1) - i(q(m) + q(m - 1))u(m - 1).\]
Therefore,
\[\langle u, Tu \rangle = \sum_{m=0}^{N-1} \langle u(m), T(u)(m) \rangle = \sum_{m=0}^{N-1} \langle u(m), i(q(m) + q(m + 1))u(m + 1) - i(q(m) + q(m - 1))u(m - 1) \rangle\]
\[= \sum_{m=0}^{N-1} \langle u(m), (q(m) + q(m - 1))u(m - 1) \rangle - \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle\]
\[= i \sum_{m=0}^{N-1} \langle (q(m) + q(m - 1))u(m), u(m - 1) \rangle - \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle\]
\[= i \sum_{m=0}^{N-1} \langle (q(m + 1) + q(m))u(m + 1), u(m) \rangle - \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle\]
\[= 2 \sum_{m=0}^{N-1} \text{Im} \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle,
\]
and
\[\langle u, Su \rangle = \sum_{m=0}^{N-1} \langle u(m), S(u)(m) \rangle = \sum_{m=0}^{N-1} \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle.
\]
\[
\sum_{m=0}^{N-1} \langle u(m), (q(m) - q(m + 1))u(m + 1) - (q(m) - q(m - 1))u(m - 1) \rangle
\]

\[
= \sum_{m=0}^{N-1} \langle u(m), (q(m) - q(m + 1))u(m + 1) \rangle - \langle u(m), (q(m) - q(m - 1))u(m - 1) \rangle
\]

\[
= \sum_{m=0}^{N-1} \langle u(m), (q(m) - q(m + 1))u(m + 1) \rangle - \langle (q(m + 1) - q(m))u(m + 1), u(m) \rangle
\]

\[
= 2 \sum_{m=0}^{N-1} \text{Re} \langle u(m), (q(m) - q(m + 1))u(m + 1) \rangle.
\]

Combining (59), (60), and (61) with inequality (58) gives the following general uncertainty principle for the vector-valued DFT.

**Theorem 8.6** (General uncertainty principle for the vector-valued DFT).

\[
\left( \sum_{m=0}^{N-1} \text{Im} \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle \right)^2
\]

\[
+ \left( \sum_{m=0}^{N-1} \text{Re} \langle u(m), (q(m) - q(m + 1))u(m + 1) \rangle \right)^2 \leq \|q u\|_2^2 \|\hat{e}^1 - \hat{e}^{-1}\| u_2^2.
\]

Theorem 8.6 holds for any real valued \( q \), but, to complete the analogy with that of the classical uncertainty principle, we desire that the operators \( Q \) and \( P \) be unitarily equivalent through the Fourier transform, in this case, the vector-valued DFT. Indeed, setting \( q = i(e^1 - e^{-1}) \), we have \( q(m)(n) = -2 \sin(2\pi ms(n)/N) \) (\( q \) is real-valued) and \( FP = QF \) as desired. With this choice of \( Q \) we have proven the following version of the classical uncertainty principle for the vector-valued DFT.

**Theorem 8.7** (Classical uncertainty principle for the vector-valued DFT). Let \( q = i(e^1 - e^{-1}) \). For every \( u \) in \( \ell^2(\mathbb{Z}/N\mathbb{Z} \times \mathbb{Z}/d\mathbb{Z}) \) we have

\[
\left( \sum_{m=0}^{N-1} \text{Im} \langle u(m), (q(m) + q(m + 1))u(m + 1) \rangle \right)^2
\]

\[
+ \left( \sum_{m=0}^{N-1} \text{Re} \langle u(m), (q(m) - q(m + 1))u(m + 1) \rangle \right)^2 \leq \|(e^1 - e^{-1}) u\|_2^2 \|\hat{e}^1 - \hat{e}^{-1}\| u_2^2.
\]

**Remark 8.8.** It is natural to extend the technique of Theorem 8.6 to vector-valued versions of recent uncertainty principle inequalities for finite frames [86], graphs [24], and cyclic groups and beyond [93, 116].
9. Appendix: Unitary representations of locally compact groups

9.1. Unitary representations. Besides the references cited in Subsection 3.3, fundamental and deep background for this Appendix can also be found in [89, 113, 114].

Let \( H \) be a separable Hilbert space over \( \mathbb{C} \), and let \( \mathcal{L}(H) \) be the space of bounded linear operators on \( H \). \( \mathcal{L}(H) \) is a *-Banach algebra with unit. In fact, one takes composition of operators as multiplication, the identity map \( I \) is the unit, the operator norm gives the topology, and the involution \( * \) is defined by the adjoint operator.

\( \mathcal{U}(H) \subseteq \mathcal{L}(H) \) denotes the subalgebra of unitary operators \( T \) on \( H \), i.e., \( TT^* = T^*T = I \).

**Definition 9.1** (Unitary representation). Let \( G \) be a locally compact group. A *unitary representation* of \( G \) is a Hilbert space \( H \) over \( \mathbb{C} \) and a homomorphism \( \pi : G \to \mathcal{U}(H) \) from \( G \) into the group \( \mathcal{U}(H) \) of unitary operators on \( H \), that is continuous with respect to the strong operator topology on \( \mathcal{U}(H) \). (The strong operator topology is explicitly defined below. It is weaker than the norm topology, and coincides with the weak operator topology on \( \mathcal{U}(H) \).)

We spell-out these properties here for convenience:

1. \( \forall g, h \in G, \pi(gh) = \pi(g)\pi(h) \);
2. \( \forall g \in G, \pi(g^{-1}) = \pi(g)^{-1} = \pi(g)^* \), where \( \pi(g)^* \) is the adjoint of \( \pi(g) \);
3. \( \forall x \in H \), the mapping \( G \to H, g \mapsto \pi(g)(x) \), is continuous.

The dimension of \( H \) is called the *dimension* of \( \pi \). When \( G \) is a finite group, then \( G \) is given the discrete topology and the continuity of \( \pi \) is immediate. We denote a representation by \( (H, \pi) \) or, when \( H \) is understood by \( \pi \).

**Definition 9.2** (Equivalence of representations). Let \( (H_1, \pi_1) \) and \( (H_2, \pi_2) \) be representations of \( G \). A bounded linear map \( T : H_1 \to H_2 \) is an *intertwining operator* for \( \pi_1 \) and \( \pi_2 \) if

\[
\forall g \in G, \quad T\pi_1(g) = \pi_2(g)T.
\]

\( \pi_1 \) and \( \pi_2 \) are said to be *unitarily equivalent* if there is a unitary intertwining operator \( U \) for \( \pi_1 \) and \( \pi_2 \).

More generally, we could consider non-unitary representations, where \( \pi \) is a homomorphism into the space of invertible operators on a Hilbert space. We do not do that here for two reasons. First, we are mainly interested in the regular representations (see Example 9.3) and these are unitary, and, second, every finite dimensional representation of a finite group is unitarizable. That is, if \( (H, \pi) \) is a finite dimensional representation (not necessarily unitary) of \( G \) and \(|G| < \infty\), then there exists an inner product on \( H \) such that \( \pi \) is unitary. See Theorem 1.5 of [84] for a proof of this fact.

**Example 9.3** (Regular representation). Let \( G \) be a finite group, and let \( \ell^2 = \ell^2(G) \). The action of \( G \) on \( \ell^2 \) by left translation is a unitary representation of \( G \). More concretely, let \( \{x_h\}_{h \in G} \) be the standard orthonormal basis for \( \ell^2 \), and define \( \lambda : G \to \mathcal{U}(\ell^2) \) by the formula,

\[
\forall g, h \in G, \quad \lambda(g)x_h = x_{gh}.
\]

\( \lambda \) is called the *left regular representation* of \( G \). The *right regular representation*, which we denote by \( \rho \), is defined as translation on the right, i.e.,

\[
\forall g, h \in G, \quad \rho(g)x_h = x_{hg^{-1}}.
\]

The construction is similar for general locally compact groups and takes place on \( L^2(G) \).
9.2. Irreducible Representations.

**Definition 9.4** (Invariant subspace). An *invariant subspace* of a unitary representation \((H, \pi)\) is a closed subspace \(S \subseteq H\) such that \(\pi(g)S \subseteq S\) for all \(g \in G\). The restriction of \(\pi\) to \(S\) is a unitary representation of \(G\) called a *subrepresentation*. If \(\pi\) has a nontrivial subrepresentation, i.e., nonzero and not equal to \(\pi\), or equivalently, if it has a nontrivial invariant subspace, then \(\pi\) is *reducible*. If \(\pi\) has no nontrivial subrepresentations or, equivalently, has no nontrivial invariant subspaces, then \(\pi\) is *irreducible*.

**Definition 9.5** (Direct sum of representations). Let \((H_1, \pi_1)\) and \((H_2, \pi_2)\) be representations of \(G\). Then,

\[
(H_1 \oplus H_2, \pi_1 \oplus \pi_2),
\]

where \((\pi_1 \oplus \pi_2)(g)(x_1, x_2) = (\pi_1(g)x_1, \pi_2(g)x_2)\), for \(g \in G, x_1 \in H_1, x_2 \in H_2\), is a representation of \(G\) called the *direct sum* of the representations \((H_1, \pi_1)\) and \((H_2, \pi_2)\).

More generally, for a positive integer \(m\), we recursively define the direct sum of \(m\) representations \(\pi_1 \oplus \ldots \oplus \pi_m\). If \((H, \pi)\) is a representation of \(G\), we denote by \(m\pi\) the representation that is the product of \(m\) copies of \(\pi\), i.e.,

\[
(H \oplus \ldots \oplus H, \pi \oplus \ldots \oplus \pi),
\]

where each sum has \(m\) terms. Clearly, a direct sum of nontrivial representations cannot be irreducible, e.g., \((H_1 \oplus H_2, \pi_1 \oplus \pi_2)\) will have invariant subspaces \(H_1 \oplus \{0\}\) and \(\{0\} \oplus H_2\).

**Definition 9.6** (Complete reducibility). A representation \((H, \pi)\) is called *completely reducible* if it is the direct sum of irreducible representations.

Two classical problems of harmonic analysis on a locally compact group \(G\) are to describe all the unitary representations of \(G\) and to describe how unitary representations can be built as direct sums of smaller representations. For finite groups, Maschke’s theorem, Theorem 9.8, tells us that the irreducible representations are the building blocks of representation theory that enable these descriptions.

**Lemma 9.7** (Invariance under unitary representations). Let \((H, \pi)\) be a unitary representation of \(G\). If \(S \subseteq H\) is invariant under \(\pi\), then \(S^\perp = \{y \in H : \forall x \in S, \langle x, y \rangle = 0\}\) is also invariant under \(\pi\).

**Proof.** Let \(y \in S^\perp\). Then, for any \(x \in S\) and \(g \in G\), we have \(\langle x, \pi(g)y \rangle = \langle \pi(g^{-1})x, y \rangle = 0\); and, therefore, \(\pi(g)y \in S^\perp\).

**Theorem 9.8** (Maschke’s theorem). Every finite dimensional unitary representation of a finite group \(G\) is completely reducible.

**Proof.** Let \((H, \pi)\) be a representation of a finite group \(G\) with dimension \(n < \infty\). If \(\pi\) is irreducible, then we are done. Otherwise, let \(S_1\) be a nontrivial invariant subspace of \(\pi\). By Lemma 9.7, \(S_2 = S_1^\perp\) is also an invariant subspace of \(\pi\). Letting \(\pi_1\) and \(\pi_2\) be the restrictions of \(\pi\) to \(S_1\) and \(S_2\) respectively, we have \(\pi = \pi_1 \oplus \pi_2\), \(\dim S_1 < n\), and \(\dim S_2 < n\). Proceeding inductively, we obtain a sequence of representations of strictly decreasing dimension, which must terminate and yield a decomposition of \(\pi\) into a direct sum of irreducible representations.
If \((H, \pi)\) is a unitary representation, we let \(C_\pi \subseteq \mathcal{L}(H)\) denote the algebra of operators on \(H\) such that
\[
\forall g \in G \text{ and } \forall T \in C_\pi, \quad T \pi(x) = \pi(x) T.
\]
\(C_\pi\) is closed under taking weak limits and under taking adjoints, and, hence, it is a von Neumann algebra. \(C_\pi\) is the commutant of \(\pi\), and it is generated by \(\{\pi(g)\}_{g \in G}\). If \(G\) is a finite group, then
\[
C_\pi = \left\{ \sum_g a_g \pi(g) : \{a_g\}_{g \in G} \subseteq \mathbb{C} \right\}.
\]
Schur’s lemma describes the commutants of irreducible unitary representations.

**Lemma 9.9** (Schur’s lemma, e.g., Lemma 3.5 of [54]). Let \(G\) be a locally compact group.

1. Let \((H, \pi)\) be a unitary representation of \(G\). \((H, \pi)\) is irreducible if and only if \(C_\pi\) contains only scalar multiples of the identity.

2. Assume \(T\) is an intertwining operator for irreducible unitary representations \((H_1, \pi_1)\) and \((H_2, \pi_2)\) of \(G\). If \(\pi_1\) and \(\pi_2\) are inequivalent, then \(T = 0\).

3. If \(G\) is Abelian, then every irreducible unitary representation of \(G\) is one-dimensional.
