Stuck walks: a conjecture of Erschler, Tóth and Werner

Daniel Kious

Université Paul Sabatier

Abstract: In this paper, we work on a class of self-interacting nearest neighbor random walks, introduced in [10], for which there is competition between repulsion at small scale and attraction at large scale. Erschler, Tóth and Werner proved in [10] that, for any $L \geq 1$, if the parameter $\alpha$ belongs to a certain interval $(\alpha L + 1, \alpha L)$, then such random walks localize on $L + 2$ sites with positive probability. They also conjectured that it is the almost sure behavior. We prove this conjecture partially, stating that the walk localizes on $L + 2$ or $L + 3$ sites almost surely, under the same assumptions. We also prove that, if $\alpha > 1$, then the walk localizes a.s. on 3 sites.

Keywords and phrases: Stuck Walks, reinforced random walks, localization, Rubin, time-line construction, martingale.

1. Introduction

Let $X := (X_n)_{n \geq 0}$ be a nearest neighbor walk on the integer lattice $\mathbb{Z}$. Let $l_k(j)$ be the local time on the non-oriented edge $(j-1, j)$ up to time $k$:

$$l_k(j) = \sum_{m=1}^{k} \mathbb{1}_{\{X_{m-1}, X_m = (j-1, j)\}}.$$

Define the filtration $(\mathcal{F}_k)_{k \in \mathbb{N}}$ generated by the process, i.e., for all $k \in \mathbb{N}$, $\mathcal{F}_k = \sigma(X_0, ..., X_k)$.

Fix a real parameter $\alpha$ and define the following linear combination of local times on neighboring and next-to-neighboring edges of a site $j$:

$$\Delta_k(j) = -\alpha l_k(j-1) + l_k(j) - l_k(j+1) + \alpha l_k(j+2), \quad (1)$$

and, with a slight abuse of notation,

$$\Delta_k := \Delta_k(X_k).$$

Fix another real parameter $\beta > 0$. In this paper, we consider the walk introduced in [10], defined by $X_0 = 0$ and the following conditional transition probability:

$$\mathbb{P}(X_{k+1} = X_k \pm 1 | \mathcal{F}_k) = \frac{e^{k\beta \Delta_k}}{e^{-\beta \Delta_k} + e^{\beta \Delta_k}}. \quad (2)$$
The linear combination $\Delta_k$ can be seen as the local stream felt by the walker. When this stream is positive (resp. negative), the walk bends toward the right (resp. toward the left). The value of the parameter $\beta$ does not affect very much the behavior of the walk, whereas the value of $\alpha$ plays a crucial role, as we explain below.

This model is a generalization of the true self-repelling walk (TSRW) in one dimension. We can recover the TSRW with edge repulsion, by choosing $\alpha = 0$, as well as the TSRW with site repulsion, by choosing $\alpha = -1$. In the case of edge repulsion, some non-degenerate scaling limits for $X_k/k^{2/3}$ are proved in [19] and the same scaling limit is conjectured for site repulsion, we refer the reader to [1, 20] for more details. Some interesting work has also been done concerning the continuous-time true self-repelling motion, see for instance [6, 7, 21]. A scaling behavior similar to the one of the edge-repelled TSRW is expected for $\alpha \in [-1, 1/3]$. Roughly speaking, $\alpha$ is then sufficiently close to 0 and this can be seen as a perturbation of the TSRW. For $\alpha \in (-\infty, -1)$, the walker is repelled by its neighboring edges and even more strongly by its next-to-neighboring edges. In this case, it seems that the walk self-builds trapping environments, which causes a slowing down of the walk. We refer the reader to [9] for more detailed discussions and arguments.

In [10], Erschler, Tóth and Werner focus on the case where $\alpha > 1/3$. In particular, the walker is repelled by its neighboring edges and attracted by its next-to-neighboring edges. Therefore, there is competition between repulsion and attraction: the last one might win, resulting in localization of the walk on an arbitrarily large interval depending on $\alpha$.

More precisely, let us define subintervals of $(1/3, +\infty)$ corresponding, as we will see later, to different possible features of the walk.

Define the sequence $(\alpha_L)_{L \geq 1}$ by $\alpha_1 = +\infty$ and for all $L \geq 2$:

$$\alpha_L = \frac{1}{1 + 2 \cos\left(\frac{2\pi}{L+2}\right)}, \quad (3)$$

so that this sequence decreases from $+\infty$ to $1/3$.

Define, for all $k \in \mathbb{N}$ and $j \in \mathbb{Z}$, the number of visits to the site $j$, up to time $k$:

$$Z_k(j) = \sum_{m=1}^{k} \mathbb{1}_{\{X_m = j\}} = \frac{l_k(j) + l_k(j + 1) + \mathbb{1}_{\{X_k = j\}} - \mathbb{1}_{\{j = 0\}}}{2}.$$

Let $R$ (resp. $R'$) be the set of points that are visited at least once (resp. infinitely often), i.e.,

$$R = \{j \in \mathbb{Z} : Z_{\infty}(j) > 0\},$$

$$R' = \{j \in \mathbb{Z} : Z_{\infty}(j) = \infty\}.$$

In [10], the authors prove the following result:
Theorem 1.1 (Erschler, Tóth and Werner, [10]). Suppose that $L \geq 1$. We have:
- If $\alpha < \alpha_L$, then, almost surely, $|R'| \geq L + 2$, or $R' = \emptyset$;
- If $\alpha \in (\alpha_{L+1}, \alpha_L)$, then the probability that $|R'| = L + 2$ is positive.
Moreover, there exists a deterministic real valued vector $(l_1, \ldots, l_{L+1})$, such that, on the event \{\(R' = \{x, x+1, \ldots, x+L+1\}\)}, we almost surely have the following law of large numbers:

$$\lim_{k \to +\infty} \frac{1}{k}(l_k(x+1), \ldots, l_k(x+L+1)) = (l_1, \ldots, l_{L+1}).$$

Remark 1.2. As in [10], we will give an explicit form for the vector $(l_1, \ldots, l_{L+1})$ later in this paper, see Proposition 4.1.

Erschler, Tóth and Werner also propose the following conjecture:

Conjecture 1.3 (Erschler, Tóth and Werner, [10]). If $\alpha \in (\alpha_{L+1}, \alpha_L)$, then $|R'| = L + 2$ almost surely.

The main goal of this paper is to prove the following result, which partially settles the conjecture.

Theorem 1.4. Assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$, then the walk localizes on $L + 2$ or $L + 3$ sites almost surely, i.e. $|R'| \in \{L + 2, L + 3\}$ a.s.

We also give, in both cases, the asymptotic behavior of the local times, which correspond to those obtained in [10], see Proposition 4.1.

When $\alpha > 1$, i.e. $\alpha \in (\alpha_2, \alpha_1)$, we can improve this result and prove the conjecture in this case, which is done in Section 7.

Theorem 1.5. Assume that $\alpha \in (1, +\infty)$, then the walk localizes on 3 sites almost surely, i.e. $|R'| = 3$ a.s.

Besides, we also believe that, for general $\alpha > 1/3$, $|R'| = L + 3$ does not occur as it corresponds to an unstable limiting behavior. So, we are looking forward to prove that, once the walk visits only $L + 3$ sites, one of the boundary site is not visited anymore after some time.

Another problem is the one of the critical values of $\alpha$, that is not treated here, neither in [10]. Nevertheless, Erschler, Tóth and Werner give good arguments to make us believe that, if $\alpha = \alpha_{L+1}$, then the walk will almost surely not be stuck on $L + 2$ sites. We encourage the reader to reach the concluding remarks of [10].

Note also that it is usually quite challenging to obtain an almost sure behavior for a reinforced random walk and let us mention some interesting results. Tarrès proved in [18] the localization on 5 sites of the vertex-reinforced random walk (VRRW) with linear reinforcement, which is an important result in the field of reinforced random walks. In [17], Tarrès proposed another proof of this result, introducing a variant of the so-called Rubin’s construction, allowing powerful couplings. This variant was also used by Basdevant, Schapira and Singh who
proved in [2] a phase transition of the behavior of VRRWs, for non-decreasing weight functions of order $n \log \log n$. The same authors, in [3], characterize sub-linear non-decreasing weight functions thanks to an index and they prove an a.s. lower bound for the size of the localization set (which is not sharp), depending on this index. They propose a conjecture with better bounds, which they prove with positive probability. In particular, they exhibit walks that localize on arbitrarily large intervals, as we do in the present paper. The major difference between the behaviors of Stuck walks and VRRWs is that in the case of VRRWs on $\mathbb{Z}$, only 3 vertices are visited during a positive proportion of the total time, and the other infinitely visited sites are seldom visited.

2. Sketch of the proof of Theorem 1.4

Let us describe the techniques used to prove Theorem 1.4. First, as in [10], we compare the local times of the walk to the solutions of a linear system. This linear system is not easy to handle generally but we prove further results on the solutions of this system, in order to generalize some results of [10] and to emphasize, through trigonometric identities, instability properties of some vertices that will force the walk to localize on one of their sides. Finally, we adapt a variant of the so-called Rubin’s construction, introduced in [17], to a class of non-monotonic weight functions.

Fix $L \geq 1$, and assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$. Let us first state the following proposition, proved in Section 5. In its proof, we compare the local times to the solutions of a linear system, as we will see below.

**Proposition 2.1.** The walk almost surely visits finitely many sites, i.e. $|R| < +\infty$ a.s.

Note that this last proposition discard the transience of the walk, i.e. $R' \neq \emptyset$ a.s.

Knowing from [10] that $|R'| \geq L + 2$ a.s., our next goal is to prove that $|R'| \leq L + 3$. Then, let $x \in \mathbb{Z}$ be the leftmost infinitely visited site, and let $K \in \mathbb{N} \cup \{0\}$ be the number of interior lattice sites of $R'$, i.e.

$$
\begin{align*}
x &= \inf \{y \in \mathbb{Z} : y \in R'\}, \\
K &= |R'| - 2,
\end{align*}
$$

Note that $x$ and $K$ are random variables but that they can take only countably many values, so we can fix $x \in \mathbb{Z}$ and $K \in \mathbb{N} \cup \{0\}$ and work on the event \{ $R' = \{x, x + 1, ..., x + K + 1\}$ = \{ $x = \inf R'$} \cap \{|R'| = K + 2\}. The following result, proved in Section 6, is crucial. It allows us to compare the asymptotic local streams and local times to the solutions of a particular linear system, as we will see below.
Proposition 2.2. Let \( x \in \mathbb{Z} \) and let \( K \in \mathbb{N} \). Almost surely, we have:

\[
\{ R' = \{ x, \ldots, x + K + 1 \} \} \subset \bigcap_{j=x+1}^{x+K} \left\{ \lim_{k \to +\infty} \frac{\Delta_k(j)}{j} = 0 \right\}.
\]

The last Proposition is a generalization of Proposition 2 of [10], which would only give us this result for \( K \leq L \), which is not sufficient. Hence, Proposition 2.2 requires a more technical proof, which needs, in particular, results of Section 4.4.

From Proposition 2.2, we know that the renormalized local times eventually approach the set of solutions \( (l_0, \ldots, l_{K+2}) \) of the linear system defined by:

\[
d_1 = d_2 = \ldots = d_K = 0 \quad \text{and} \quad \sum_{j=1}^{K+1} l_j = 1,
\]

where, for all \( j \in \{1, \ldots, K\} \), \( d_j = -\alpha l_{j-1} + l_j - l_{j+1} +\alpha l_{j+2} \), and with the extra conditions \( l_0 = l_{K+2} = 0 \).

So, all the information we can get about this system gives us information about the asymptotic behavior of the local times. All the purpose of Section 4 is to study this generalized Fibonacci sequence and its solutions. In fact, we also use some properties of the solutions of this system to prove Proposition 2.1 and Proposition 2.2.

Let us roughly describe the solutions of such a system, which is detailed in Section 4. First, define \( d_0 = -l_1 + \alpha l_2 \) and \( d_{K+1} = -\alpha l_K + l_{K+1} \).

If \( K < L \), then the solution to the system is unique, all the \( l_j \)'s are positive, \( d_0 \) is negative and, by symmetry, \( d_{K+1} = -d_0 > 0 \). As \( \Delta_k(x)/k \) and \( \Delta_k(x + K + 1)/k \) respectively approach \( d_0 \) and \( d_{K+1} \) as \( k \) goes to infinity, it gives us the intuition that we cannot have \( |R'| < L + 2 \), since otherwise the local streams at the bounds would strongly push the walker out of this interval.

If \( K = L \), then the solution is still unique, with all the \( l_j \)'s positive, and we have \( d_0 = -d_{L+1} > 0 \). So, we guess that \( |R'| = L + 2 \) is a good candidate, as the local streams on the bounds would keep the walker inside the interval.

If \( K = L + 1 \), the unique solution is similar to the previous one, which makes \( |R'| = L + 3 \) another good candidate.

Otherwise, if \( K > L + 1 \), the solutions of the system are not necessarily unique, and we cannot define \textit{a priori} the sign of \( d_0 \) nor \( d_{K+1} \). Moreover, as it is noticed in [10], see also Remark 4.4, we could find many \( K \)'s for which the set of solutions to the system is such that all the \( l_j \)'s are non-negative, \( d_0 > 0 \) and \( d_{K+1} < 0 \), i.e. that the local streams on the bounds push the walker inward. In other words, we could find many good candidates for the size of \( R' \). The goal is then to exclude these larger values of \( K \).

Remind that \( L \geq 1 \) and that \( \alpha \in (\alpha_{L+1}, \alpha_L) \). The following lemma is a bit less general than Proposition 4.7 which we state and prove in Section 4.4. As we have already noticed, the linear system is quite difficult to handle when \( K \) is large, but we can prove some useful results under some convenient assumptions.
Lemma 2.3. Assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$ and $K \geq L$. If $(l_0, \ldots, l_{K+2})$ satisfies the previous system and if $l_1, \ldots, l_{K+1} \geq 0$, then:

(i) $d_0 \geq c(K)$ and $d_{K+1} \leq -c(K)$, where $c(K)$ is a positive constant depending only on $\alpha$ and $K$.

(ii) for the same positive constant $c(K)$, we have

\[
l_{L+2} - \alpha l_{L+1} = -\frac{\sin(L+\frac{1}{2}\omega)}{\sin(L\frac{1}{2} \omega)} l_1 + 2\alpha \frac{\cos(L+\frac{3}{2}\omega)}{\sin(L\frac{3}{2} \omega)} l_{L+1} \leq -c(K).
\]

The first point is used to prove Proposition 2.2, whereas the second point is used to prove the following series convergence.

Lemma 2.4. Let $x, K \in \mathbb{Z}$ such that $K \geq L$, and fix $a > 0$. Then, almost surely,

\[
\{R' = \{x, \ldots, x + K + 1\} \} \subset \left\{ \sum_{k=1}^{+\infty} e^{a|\alpha_l(x+L+2)-\alpha l_k(x+L+1)|} < +\infty \right\}.
\]

Its proof is simple but needs several technical details to be rigorous, so we just give here an idea of the complete proof which is set forth in Section 6.2. By Proposition 2.2, we know that, on the event $\{R' = \{x, \ldots, x + K + 1\}\}$, for all $j \in \{1, \ldots, K\}$, the local stream $\Delta_k(x+j)/k$ converges to 0. Hence, the vector of local times $(l_k(x+1), \ldots, l_k(K+1))/k$ approaches, as $k$ goes to infinity, the set of solutions to the linear system introduced in the previous paragraph. Then, Lemma 2.3 implies that $(l_k(x+L+2) - \alpha l_k(x+L+1))/k$ is asymptotically smaller than some negative constant. Lemma 2.4 is then no more surprising. Let us explain later in this section how we use this result: we will consider the series as a sum of means of exponential clocks.

To prove Theorem 1.4 we adapt a variant of the so-called Rubin’s construction, which consists in a coupling between the original walk and continuous time-lines. It was first used by Davis in [5] and Sellke in [16]. Tarrès introduced a variant of this time-line construction in [17], involving powerful couplings, that seems to be efficient for a large class of reinforced random walks. It has been mostly used so far for nearest-neighbor reinforced random walks on the integer lattice $\mathbb{Z}$, with transition probabilities given by

\[
P(X_{k+1} = X_k - 1 | \mathcal{F}_k) = \frac{w(Z_k(X_k - 1))}{w(Z_k(X_k - 1)) + w(Z_k(X_k + 1))},
\]

namely vertex-reinforced random walks (VRRW), with a positive non-decreasing weight function $w$. Particularly, by a result of [17], this construction yields, for any $y \in \mathbb{Z}$, a.s.,

\[
\left\{ \sum_{k=0}^{+\infty} \frac{\mathbb{I}\{X_k=y, X_{k+1}=y+1\}}{w(Z_k(y+1))} < +\infty \right\} = \left\{ \sum_{k=0}^{+\infty} \frac{\mathbb{I}\{X_k=y, X_{k+1}=y-1\}}{w(Z_k(y-1))} < +\infty \right\} = \left\{ Z_\infty(y-1) \wedge Z_\infty(y+1) < \infty \right\}.
\]
Here, the transition probabilities do not fulfill these conditions. In particular, we do not have any monotonicity. But we take advantage of some different ways to write the probability for the walker to jump on his left when he is on a certain vertex:

\[
P(X_{k+1} = X_k - 1 | F_k) = \frac{1}{1 + e^{2\beta \Delta_k}} \quad (4)
\]

\[
= \frac{e^{2\beta[-l_k(X_k) + \alpha l_k(X_k-1)]}}{e^{2\beta[-l_k(X_k) + \alpha l_k(X_k-1)]} + e^{2\beta[-l_k(X_k+1) + \alpha l_k(X_k+2)]}}. \quad (5)
\]

The important fact is that (5) makes occur two terms: one depending only on the local times on edges on the left of the considered vertex and the second one depending only on the local times on edges on the right of it. Hence, after one excursion on the right, or on the left, of this vertex, only one of the two terms would have changed. Note that we still do not have any monotonicity, but, as we will see, we can construct time-lines corresponding to a continuous-time version of the walk and we will be able to generalize some results of Tarrèes to a class of non-monotonic weight functions.

Before making this construction more precise, let us introduce some definitions. First, for all \(y \in \mathbb{Z}\) and \(k \in \mathbb{N}\), define the number of times the oriented edge \((y, y \pm 1)\) has been crossed, up to time \(k\):

\[
N_k(y, y \pm 1) = \sum_{n=0}^{k-1} \mathbb{1}_{\{X_n = y, X_{n+1} = y \pm 1\}},
\]

and notice that if \(X_k = y\) then we have:

\[
Z_k(y \pm 1) = \frac{l_k(y + \frac{y \pm 1}{2}) + l_k(y + \frac{y \pm 3}{2}) - \mathbb{1}_{\{y \pm 1 = 0\}}}{2},
\]

\[
N_k(y, y \pm 1) = \frac{l_k(y + \frac{y \pm 1}{2}) - \mathbb{1}_{\{\pm y < 0\}}}{2}.
\]

Define two functions \(f^+\) and \(f^-\) from \(\mathbb{Z} \times \mathbb{N} \cup \{0\}\) to \(\mathbb{R}^+\), and a function \(w\) from \(\mathbb{N} \cup \{0\}\) to \(\mathbb{R}^+\), such that, for all \(n \in \mathbb{N} \cup \{0\}\) and \(y \in \mathbb{Z}\),

\[
f^\pm(y, n) = \exp\left(2\beta \left[2(1 + \alpha) n - \alpha \mathbb{1}_{\{y \pm 1 = 0\}} + (1 + \alpha) \mathbb{1}_{\{\pm y < 0\}} \right]\right), \quad (6)
\]

\[
w(n) = \exp(2\beta \times 2\alpha \times n). \quad (7)
\]

Then, if \(X_k = y\), we have

\[
e^{2\beta[-l_k(y+1) + \alpha l_k(y+2)]} = \frac{w(Z_k(y+1))}{f^+(y, N_k(y, y + 1))}, \quad (8)
\]

\[
e^{2\beta[-l_k(y) + \alpha l_k(y-1)]} = \frac{w(Z_k(y-1))}{f^-(y, N_k(y, y - 1))}. \quad (9)
\]
hence, using (5),
\[
\mathbb{P}(X_{k+1} = X_k - 1|\mathcal{F}_k) = \frac{w(Z_k(X_k-1))}{f^{-1}(X_k, N_k(X_k, X_k-1)) + w(Z_k(X_k+1))}.
\]
(10)
for the rest of the argument. Note that, on this event, $|R'| \geq L + 4$, and $\{x, x+1, ..., x+L+3\} \subset R'$.

Now, we are going to use the Rubin’s construction, which is the following. Remind that, in our case, the function $w$ is defined as in (7), but this construction can be done for any non-decreasing weight function. This variant was introduced in [17] but the way we present this construction is very similar to the one in [2], as it is more appropriate to the present problem. We will couple the walk with continuous time-lines corresponding to sequences of clocks. More precisely, fix a collection of positive real numbers:
\[
\xi := (\xi_k^+(y), \xi_k^-(y), y \in \mathbb{Z}, k \geq 0) \in \mathbb{R}_+^\mathbb{N}.
\]
We call $\mathcal{M}$ the function which maps a collection of positive real numbers $\xi$ to a continuous-time walk $\tilde{X} = (\tilde{X}_t)_{t \in \mathbb{R}_+} := \mathcal{M}(\xi)$ on $\mathbb{Z}$, constructed as follows. $\{y-1, y\}$ has been crossed and the number of visits to $y$ up to time $t > 0$. We define $\tilde{I}_t(y)$ and $\tilde{Z}_t(y)$ as right-continuous on $t$. We adopt also the natural notation $\tilde{R}'$.

For each $y \in \mathbb{Z}$ and $k \in \mathbb{N} \cup \{0\}$, the value $\xi_k^+(y)$ (resp. $\xi_k^-(y)$) will be related to the duration of a clock attached to the oriented edge $(y, y+1)$ (resp. $(y, y-1)$), and given the collection $\xi$, the evolution of the walk is deterministic, created as follows:

- Set $\tilde{X}_0 = 0$ and attach two clocks to the oriented edges $(0, -1)$ and $(0, 1)$ ringing respectively at times $\xi_0^-(0)/w(0)$ and $\xi_0^+(0)/w(0)$.
- At time $\tau_1 := (\xi_0^-(0)/w(0)) \land (\xi_0^+(0)/w(0))$, one of the alarms rings, then the walker crosses instantaneously the corresponding edge and both clocks are stopped. Then, we have set $\tilde{X}_{\tau_1} = \pm 1$ depending on which clock has rung first. If both clocks ring at the same time, then $\tilde{X}$ stays at 0 forever and we say that the construction fails.

Now, assume that we have constructed $\tilde{X}$ up to some time $t > 0$ at which time the process makes a right jump from $y-1$ to $y$, for some vertex $y \in \mathbb{Z}$. Denote by $k$ the number of jumps from $y$ to $y-1$ and by $n$ the number of visits to $y-1$ before time $t$. We continue the construction according to the following procedure:

- Start a new clock attached to the oriented edge $(y, y-1)$, which will ring after a time $\xi_k^-(y)/w(n)$.
- If the walk has already been in $y$ previously, then restart the clock attached to the oriented edge $(y, y+1)$ that has been stopped (without ringing) the
last time the process left $y$. Otherwise, start a new clock for $(y, y+1)$ which will ring after a time $\xi_0^+(y)/w(0)$.

- When one of the alarms rings, the walker crosses instantaneously the corresponding edge, and both clocks are stopped. If both alarms ring simultaneously, then $\tilde{X}$ stays at $y$ forever and we say that the construction fails.

We follow the symmetric procedure when the process jumps from $y+1$ to $y$.

\end{figure}

Let us naturally adopt the notations $\tilde{F}_t$, $I_k(y)$, $\tilde{N}_k(y, y, y \pm 1)$, $\tilde{Z}_t(y)$ inherited from $F_k$, $I_k(y)$, $N_k(y, y, y \pm 1)$, $Z_k(y)$.

Let us define $\tau_0 := 0$ and $\tau_k$ the time of the $k$-th jump of $\tilde{X}$. Then, define the discrete-time embedded walk $(\tilde{X}_{\tau_k})_k$.

As it is noticed in [17] we can recover, from this construction, the law of a VRRW with weight $w$ by choosing $\xi$ to be a collection of independent exponential random variables with mean 1.

Here, the dynamics are different from those of a VRRW, but reminding the definitions (6) of $f^\pm$, (7) of $w$, and the transition probability (10), we prove the following proposition.

**Proposition 2.5.** Choose $\xi$ to be such that, for all $y \in \mathbb{Z}$ and $k \in \mathbb{N} \cup \{0\}$, $\xi_k^\pm(y)$ are exponential random variables, independent from each other, and with mean $f^\pm(y, k)$. Define the continuous-time walk $\tilde{X} := \mathcal{M}(\xi)$ and its embedded walk $(\tilde{X}_{\tau_k})_k$.

Then the construction of $\tilde{X}$ does not fail with probability 1. Moreover, the processes $(\tilde{X}_{\tau_k})_{k \geq 0}$ and $(X_k)_{k \geq 0}$ have the same distribution.

**Proof.** Remind that if $U$ and $V$ are two independent exponential random variables of parameter $u$ and $v$ (i.e. with mean $1/u$ and $1/v$), then $\mathbb{P}(U < V) = u/(u+v)$ and $\mathbb{P}(U = V) = 0$.

Then, it suffices to remind (10) and to notice that, conditionally on $\tilde{F}_{\tau_k}$, the quantities $\xi_{N_k^\pm}(\tilde{X}_{\tau_k}, \tilde{X}_{\tau_k, y \pm 1})/(w(\tilde{Z}_{\tau_k}(\tilde{X}_{\tau_k} \pm 1)))$ are independent exponential random variables with respective means

\[
\frac{f^+(\tilde{X}_{\tau_k}, \tilde{N}_{\tau_k}(\tilde{X}_{\tau_k}, \tilde{X}_{\tau_k} + 1))}{w(\tilde{Z}_{\tau_k}(\tilde{X}_{\tau_k} + 1))} \quad \text{and} \quad \frac{f^-(\tilde{X}_{\tau_k}, \tilde{N}_{\tau_k}(\tilde{X}_{\tau_k}, \tilde{X}_{\tau_k} - 1))}{w(\tilde{Z}_{\tau_k}(\tilde{X}_{\tau_k} - 1))}.
\]
Until the end of this section, we work with \( \xi \) defined as in this last Proposition, which then implies that \((\tilde{X}_k)_{k}, (\tilde{Z}_{\tau_k}(y))_{k,y}, (\tilde{I}_{\tau_k}(y))_{k,y}\) and \(\tilde{R}'\) have the same laws as \((X_k), (Z_k(y)), (I_k(y))\) and \(R'\).

The following results were introduced in [17]. Define, for each \(y \in \mathbb{Z}\), the total time consumed by the clocks attached to the oriented edge \((y, y \pm 1)\):

\[
T_{y}^{\pm} : = \sum_{k \geq 0} 1_{\{\tilde{X}_{\tau_k} = y, \tilde{X}_{\tau_k+1} = y \pm 1\}} \frac{\xi_{N_{\tau_k}(y,y \pm 1)}(y)}{w(Z_{\tau_k}(y \pm 1))},
\]

\((11)\)

From the time-line construction, it is clear that

\[
\{\tilde{Z}_\infty(y-1) = \infty\} \cap \{\tilde{Z}_\infty(y+1) = \infty\} \cap \{T_y^+ \wedge T_y^- < \infty\} \
\subset \{T_y^+ = T_y^- < \infty\} \quad (12)
\]

since otherwise, after a certain time, the walk would jump infinitely many times on one side of \(y\) before performing one more jump on the other side.

Section 3.1 is dedicated to proving the next Proposition, using monotonicity properties of the time-line construction, emphasized in [17], which fit here too.

**Proposition 2.6.** If \(\tilde{X}\) is a continuous-time process defined as in Proposition 2.5, then, for any \(y \in \mathbb{Z}\),

\[
P \left( T_y^+ = T_y^- < \infty, \tilde{Z}_\infty(y-1) = \tilde{Z}_\infty(y+1) = \infty \right) = 0.
\]

The following Proposition is proved in Section 3.2, using martingale arguments.

**Proposition 2.7.** If \(\tilde{X}\) is a continuous-time process defined as in Proposition 2.5, then, for any \(y \in \mathbb{Z}\),

\[
\left\{ \sum_{k=0}^{+\infty} e^{2j[\tilde{I}_{\tau_k}(y) - \tilde{I}_{\tau_k}(y-1)]} < \infty, j \in \{1, 2\} \right\} \subset \{T_y^- < \infty\}.
\]

Now, fix \(x \in \mathbb{Z}\) and fix \(K \geq L + 2\), then \(\{\tilde{R}' = \{x, ..., x + K + 1\}\} \subset \{|\tilde{R}'| \geq L + 4\}\).

Using the series convergence of Lemma 2.4 and Proposition 2.7, we deduce

\[
\{\tilde{R}' = \{x, ..., x + K + 1\}\} \subset \{T_{x+L+2}^- < +\infty\}.
\]

Hence, using the inclusion (12),

\[
\{\tilde{R}' = \{x, ..., x + K + 1\}\} \subset \{T_{x+L+2}^- = T_{x+L+2}^+ < +\infty\}.
\]

Therefore, using Proposition 2.6, it implies that

\[
P \left( \tilde{R}' = \{x, ..., x + K + 1\} \right) = 0.
\]
Taking finally the union over $x \in \mathbb{Z}$ and $K \geq L + 2$, and using Proposition 2.5, we conclude that
\[ P(|R'| \geq L + 4) = P(|\tilde{R}'| \geq L + 4) = 0. \]

3. Monotonicity of the time-line construction and martingale arguments

In Section 3.1, we prove Proposition 2.6 by taking advantage of some monotonicity properties occurring in the time-line construction. The whole proof is due to Tarrès, [17], but we use, at the end of this proof, a more convenient argument, due to Basdevant, Schapira and Singh, [2].

In Section 3.2, we use martingale arguments to prove Proposition 2.7.

Remark 3.1. In this article, we generalize some results of Tarrès, [17], to a class of dynamics involving non-monotonic weight function. More precisely, all the results of this Section hold for any positive functions $f^\pm(.,.)$, and any positive non-decreasing function $w(.)$. Notice that $w/f^\pm$ can be non-monotonic. But note that one could prove a generalized version of the forthcoming Lemma 3.3 of Tarrès,[17], and prove that all these results hold as soon as a process $X'$ is described by the following transition probability:

\[
P(X'_{k+1} = X'_k - 1|F_k) = \frac{\tilde{w}(Z_k(X'_k - 1),...,Z_k(X'_k - n_0))}{f^-(X'_k,N_k(X'_k,X'_k - 1))} + \frac{w(Z_k(X'_k + 1),...,Z_k(X'_k + n_0))}{f^+(X'_k,N_k(X'_k,X'_k + 1))},
\]

for some $n_0 \in \mathbb{N}$ and for any $k \in \mathbb{N}$, where the functions $f^\pm$ are positive and where $\tilde{w}$ is positive and non-decreasing with respect to each variable. Note that the resulting term $\tilde{w}/f^\pm$ can be non-monotonic.

3.1. Proof of Proposition 2.6

Remind the time-line construction introduced in the previous Section, in which we have defined the function $M$ which maps a collection $\xi$ of positive real numbers to a continuous-time walk $M(\xi)$.

We are here going to couple and compare a family of continuous-time walks with convenient monotonicity properties, highlighted by Tarrès, [17]. We will be able to use these results because we use the same time-line construction, with the particular weight function $w : n \mapsto \exp(4\alpha\beta n)$, except that we choose the clocks with different laws (defined in Proposition 2.5).

Let us first introduce a definition.
Definition 3.2. Given \( \xi^1 = ((\xi^1_k(y))_{y \in \mathbb{Z}, k \geq 0} \) and \( \xi^2 = ((\xi^2_k(y))_{y \in \mathbb{Z}, k \geq 0} \) two collections of random variables on \( \mathbb{R}_+ \), we say that \( \xi^1 \gg \xi^2 \) if, for all \( k \geq 0 \) and \( y \in \mathbb{Z} \), we have that \( (\xi^1_k(y)) \leq (\xi^2_k(y)) \) and \( (\xi^1_k(y)) \geq (\xi^2_k(y)) \) almost surely.

Before citing the next Lemma due to Tarrès, let us define two continuous-time walks \( \widetilde{X}^1 := \mathcal{M}(\xi^1) \) and \( \widetilde{X}^2 := \mathcal{M}(\xi^2) \), adopting the natural notations \( \widetilde{Z}^1_y(y) \) and \( \widetilde{Z}^2_y(y) \), for any \( y \in \mathbb{Z} \). For any \( i \in \mathbb{N} \) and any \( y \in \mathbb{Z} \), let \( n_{(y,y+1)}^1(i) \) (resp. \( n_{(y,y+1)}^2(i) \)) be the time of the \( i \)-th visit of \( \widetilde{X}^1 \) (resp. \( \widetilde{X}^2 \)) to the non-oriented edge \( \{y, y+1\} \), with the convention that \( n_{(y,y+1)}^1(0) = n_{(y,y+1)}^2(0) = 0 \).

Lemma 3.3 (Tarrès, [17]). Assume that \( \xi^1 \gg \xi^2 \) and that the constructions of \( \widetilde{X}^1 \) and \( \widetilde{X}^2 \) do not fail, then, for any \( i \in \mathbb{N} \) and \( y \in \mathbb{Z} \), we almost surely have that

\[
\widetilde{Z}^1_{n_{(y,y+1)}^1(i)}(y+1) \geq \widetilde{Z}^2_{n_{(y,y+1)}^2(i)}(y+1) \text{ and } \widetilde{Z}^1_{n_{(y,y+1)}^1(i)}(y) \leq \widetilde{Z}^2_{n_{(y,y+1)}^2(i)}(y).
\]

Arguments from [17] could allow us to conclude, but we will follow those of [2], which are a bit different and slightly shorter.

Proof of Proposition 2.6. In order to apply the last Lemma, fix \( y \in \mathbb{Z} \) and define the collection:

\[
\mathcal{H}_y := \left( (\xi^1_k(x), k \geq 0, x \neq y), (\xi^1_k(y), k \geq 0), (\xi^1_k(y), k \geq 1) \right),
\]

where the \( \xi^1 \)'s are independent and defined as in Proposition 2.5, i.e. \( \xi^1_k(x) \) is an exponential random variable with mean \( f^\pm(x,k) \).

Then, note that the process \( \widetilde{X} \) defined in Proposition 2.5 has the same law as \( \mathcal{M}(\mathcal{H}_y, \xi^1_0(y)) \), where \( \xi^1_0(y) \) is an exponential random variable with mean 1, independent from \( \mathcal{H}_y \). This means that \( X \) has the same law as the embedded walk of \( \mathcal{M}(\mathcal{H}_y, \xi^1_0(y)) \).

Moreover, we can create a family of walks \( \widetilde{X}^{(u)} := \mathcal{M}(\mathcal{H}_y, u), u > 0 \), which correspond to continuous-time walks defined according to the time-line construction, with \( \xi^1_0(y) = u \).

For all \( u > 0 \), in a way similar to (11), define:

\[
T^\pm_y(\mathcal{H}_y, u) = \sum_{k \geq 0} \mathbb{1}_{\{ X_{n_k}^{(u)} = y, X_{n_k+1}^{(u)} = y \pm 1 \}} \frac{\xi^\pm_{N_k^{(u)}}(y, y \pm 1)}{w(\widetilde{Z}_k^{(u)}(y \pm 1))},
\]

\[
= \sum_{k=0} \frac{\xi^\pm_{k}(y)}{w(\widetilde{Z}_k^{(u)}(y \pm 1))},
\]

which is the total time consumed by the clocks attached to the oriented edge \( (y, y \pm 1) \) for the walk \( X^{(u)} \).
Then, Lemma 3.3 implies that, for any \( u, u' > 0 \) such that \( u > u' \), almost surely on the event \( \{ T_y^+(H_y, u), T_y^+(H_y, u') < \infty \} \cap \{ \tilde{Z}_\infty^{(u)}(y\pm1) = \infty \} \), we have that

\[
T_y^+(H_y, u) > T_y^+(H_y, u') \quad \text{and} \quad T_y^-(H_y, u) \leq T_y^-(H_y, u').
\]

Thus, it implies that, given \( H_y \), there exists at most one value \( u_0 = u_0(H_y) \) of \( \xi_0^+(y) \) such that the event \( \{ T_y^+ = T_y^- < \infty \} \cap \{ \tilde{Z}_\infty(y+1) = \tilde{Z}_\infty(y-1) = \infty \} \) occurs. If such a value does not exist, then we use the convention \( u_0 = \infty \).

Note that \( \{ \tilde{Z}_\infty(y+1) = \tilde{Z}_\infty(y-1) = \infty \} \) implies that the construction succeed, which is already proved to happen a.s.

Then we conclude with

\[
\mathbb{P} \left( T_y^+ = T_y^- < \infty, \tilde{Z}_\infty(y+1) = \tilde{Z}_\infty(y-1) = \infty \right) \leq \mathbb{E} \left( \mathbb{P} \left( \xi_0^+(y) = u_0(H_y) \right) \right) = 0.
\]

\[\square\]

3.2. Proof of Proposition 2.7

The following arguments are similar to those of [17] and the notations are those of [2].

Fix \( y \in \mathbb{Z} \) and assume for simplicity that \( y > 0 \) (but similar arguments holds whenever \( y \leq 0 \)). Let \( \theta_k \) be the time of the \( k \)-th jump from \( y-1 \) to \( y \), and let \( i_k \) be the local time at site \( y-1 \), at time \( \theta_k \). Define a new filtration \( \mathcal{G} \) such that, for all \( n \geq 0 \), we have

\[
\mathcal{G}_n = \sigma \left( \left( \xi_k^+(x), k \geq 0, x \neq y \right), \left( \xi_k^-(y), k \geq 0 \right), (\xi_k^-(y), 0 \leq k \leq n) \right),
\]

and recall that the \( \xi \)'s are exponential clocks defined as in Proposition 2.5. For any \( n \geq 0 \), define

\[
Y_y^-(n) := \sum_{k=0}^n \mathbb{1}_{\{ \theta_{k+1} < \infty \}} \frac{f^-(y, k)}{w(i_{k+1})},
\]

\[
T_y^-(n) := \sum_{k=0}^n \mathbb{1}_{\{ \theta_{k+1} < \infty \}} \frac{\xi_k^-(y)}{w(i_{k+1})},
\]

\[
M_n := T_y^-(n) - Y_y^-(n),
\]

\[
\langle M \rangle_n := \sum_{k=0}^n \mathbb{E} \left( \left( M_{k+1} - M_k \right)^2 \mid \mathcal{G}_k \right).
\]

Notice that, given \( \mathcal{G}_n \), we know the duration of the \( n + 1 \) first clocks attached to the oriented edge \((y, y-1)\), and the duration of any other clock attached to any other edge.
Then, as $y > 0$, $\theta_{n+2}$ and thus $i_{n+2}$ are $G_n$-measurable, whereas $\xi_{n+1}(y)$ is independent of $G_n$. We have:

$$
E(M_{n+1} - M_n | G_n) = \frac{\mathbb{1}_{\{\theta_{n+2} < \infty\}}}{w(i_{n+2})} E\left(\xi_{n+1}(y) - f^{-}(y, n + 1)\right) = 0,
$$

$$
E((M_{n+1} - M_n)^2 | G_n) = \frac{\mathbb{1}_{\{\theta_{n+2} < \infty\}}}{w(i_{n+2})} E\left((\xi_{n+1}(y) - f^{-}(y, n + 1))^2\right) = \frac{\mathbb{1}_{\{\theta_{n+2} < \infty\}} (f^{-}(y, n + 1))^2}{(w(i_{n+2}))^2}.
$$

hence, $M_n$ is a square integrable $G$-martingale. By a result of Doob, we know that $M_n$ converges a.s. to a finite limit on the event $\{\langle M \rangle_\infty < \infty\}$, see [13], Proposition VII-2.3. Thus, on the event $\{\langle M \rangle_\infty < \infty\} \cap \{Y_{\infty}^- < \infty\}$, we have a.s. $T_y^- = \lim_n T_y^- (n) < \infty$.

Besides, (9) implies:

$$
Y_{\infty}^- \leq \sum_{k=0}^{+\infty} e^{2\beta[I_{\infty}(y) - \alpha I_{\infty}(y-1)]},
$$

$$
\langle M \rangle_\infty \leq \sum_{k=0}^{+\infty} e^{4\beta[I_{\infty}(y) - \alpha I_{\infty}(y-1)]}.
$$

Thus, the following inclusion holds a.s.

$$
\left\{\sum_{k=0}^{+\infty} e^{2j\beta[I_{\infty}(y) - \alpha I_{\infty}(y-1)]} < \infty, j \in \{1, 2\}\right\} \subset \{T_y^- < \infty\}.
$$

**Remark 3.4.** Note that, in fact, we do not need the explicit form of $f^\pm$ and $w$. More generally, for any positive function $f^\pm$ and $w$, the inclusions $\{Y_{\infty}^- < \infty\} \subset \{\langle M \rangle_\infty < \infty\}$ and consequently $\{Y_{\infty}^- < \infty\} \subset \{T_y^- < \infty\}$ hold.

4. Trigonometric results

4.1. Definition of the linear system

Fix $L \geq 1$ and assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$, where $(\alpha_L)_{L \geq 1}$ is defined in (3). We will describe some properties of the set of possible solutions $(l_0, ..., l_{K+2})$ to linear equations that are part of a bi-infinite Fibonacci-type sequence. First, we introduce this linear system, then we distinguish between three cases, depending on the size of the system.

For all $K \in \mathbb{N}$ and for all $j \in \{1, ..., K\}$, let

$$
d_0 = l_0 - l_1 + \alpha l_2,
$$

$$
d_j = -\alpha l_{j-1} + l_{j} - l_{j+1} + \alpha l_{j+2},
$$

$$
d_{K+1} = -\alpha l_k + l_{K+1} - l_{K+2}.
$$

(15)
For all \( K \in \mathbb{N} \), define the linear system:

\[
d_1 = d_2 = ... = d_K = 0, \quad l_0 = 0 \quad \text{and} \quad \sum_{j=1}^{K+1} l_j = 1. \quad (E_K)
\]

Let \( \omega \in (0, \pi) \) be the unique real number such that:

\[
\cos(\omega) = \frac{1 - \alpha}{2\alpha},
\]

then, using (3),

\[
\frac{2\pi}{L+3} < \omega < \frac{2\pi}{L+2}.
\]

In Section 4.2, we describe the unique solution of the linear system \((E_K)\) with the extra condition \(l_{K+2} = 0\), when \( K \) is small, namely \( K \in \{0, ..., L+1\} \). In Section 4.3, we prove some properties of an associated affine system when \( K = L \). In other words, we consider the same system, but with general \( d_j \)'s (i.e. not necessarily equal to 0), and we emphasize some identities. In Section 4.4, we describe some properties of the solutions of the linear system \((E_K)\), with the conditions \(l_1, ..., l_{K+2} \geq 0\), when \( K \) is large, i.e. \( K \geq L \). We also prove Lemma 2.3. We refer the reader to [11], for instance, for known properties of these solutions.

### 4.2. Small-size system: \( K \in \{0, ..., L+1\} \)

The following Proposition gives an explicit form for the solution of \((E_K)\), with \( l_{K+2} = 0 \), when \( K \) is small, i.e. \( K \in \{0, ..., L+1\} \). As we prove in Section 6, these solutions correspond to the asymptotic renormalized local times of the walk, on the corresponding events.

**Proposition 4.1.** If \( \alpha \in (\alpha_{L+1}, \alpha_L) \) and \( K \in \{0, ..., L+1\} \), then the solution of \((E_K)\), with the extra condition \(l_{K+2} = 0\), is unique and satisfies:

\[
l_j = \sin\left(\frac{K+2-j}{2}\omega\right) \sin\left(\frac{j\omega}{2}\right) \quad \text{for all} \quad j \in \{0, ..., K+2\},
\]

where \( Z \) is a normalization constant. Moreover,

\[
d_0 = -d_{K+1} = -\alpha \frac{\sin((K+3/2)\omega) \sin\left(\frac{3\omega}{2}\right)}{Z}.
\]

The same conclusions hold when \( \alpha = \alpha_L \) and \( K \in \{1, ..., L-1\} \).

Note that \( l_1, ..., l_{K+1} \) are positive. Moreover, if \( K \in \{0, ..., L-1\} \) (resp. \( K \in \{L, L+1\} \)), then \( d_0 < 0 \) (resp. \( d_0 > 0 \)).

**Remark 4.2.** We will later deal with two different systems \((E_K)\) and \((E_{K'})\) together, with \( K \neq K' \). We will then use the notations \( d_0(K) \), \( d_{K+1}(K) \) and \( d_0(K') \), \( d_{K'+1}(K') \) in order to avoid any confusion.
Proof. All the arguments in the beginning of this proof, until (20), hold for any $K \in \mathbb{N}$ and will be used later.

Let us first emphasize the fact that the set of solutions of the system $d_1 = \ldots = d_K = 0$ is 3-dimensional. Indeed, let $(l_0, \ldots, l_{K+2})$ be a real-valued vector satisfying $d_1 = \ldots = d_K = 0$. If we fix $l_0$, $l_1$ and $l_2$, then it is easy to see that, by induction, we can find a unique solution. It implies that the set of solutions is 3-dimensional.

Moreover, these solutions satisfy linear recurrence relations with characteristic polynomial $P(X) = \alpha X^3 - X^2 + X - \alpha = \alpha(X-1)(X-e^{i\omega})(X-e^{-i\omega})$, hence the general solutions to $(E_0)$ are such that:

$$l_j = A + Be^{ij\omega} + Ce^{-ij\omega}, \quad \text{for all } j \in \{0, \ldots, K+2\},$$

for some constants $A, B, C \in \mathbb{C}$. Recall that $\omega$ is such that $\cos(\omega) = (1 - \alpha)/2\alpha$

Then, using the conditions $l_0 = 0$, $l_{K+2} = 0$ and $\sum l_j = 1$, we can compute $A$, $B$ and $C$, which will imply the uniqueness of the solution $(l_0, \ldots, l_{K+2})$ of $(E_K)$ with $l_{K+2} = 0$.

First, the condition $l_0 = A + B + C = 0$ implies

$$l_j = A(1 - e^{ij\omega}) + C(e^{ij\omega} - e^{-ij\omega}).$$

(19)

Now, let us write $l_j$ as a function of $A$ and $l_{j_0}$, for some $j_0 \in \{1, \ldots, (L+3) \land (K+2)\}$.

As $2\pi/(L+3) < \omega < 2\pi/(L+2)$, we have $e^{ij_0\omega} - e^{-ij_0\omega} \neq 0$, for any $j_0 \in \{1, \ldots, (L+3) \land (K+2)\}$. Now fix $j_0 \in \{1, \ldots, (L+3) \land (K+2)\}$, then (19) applied to $j = j_0$ implies that:

$$C = \frac{A(1 - e^{ij_0\omega}) - l_{j_0}}{e^{ij_0\omega} - e^{-ij_0\omega}},$$

and, for all $j \in \{1, \ldots, K+2\}$, we have:

$$l_j = A \left(1 - e^{ij\omega}\right) + \left(A \left(e^{ij_0\omega} - 1\right) + l_{j_0}\right) \frac{e^{ij\omega} - e^{-ij\omega}}{e^{ij_0\omega} - e^{-ij_0\omega}}$$

$$= \frac{\sin(j\omega)}{\sin(j_0\omega)} l_{j_0} + A \frac{\sin(j_0\omega) - \sin((j_0 - j)\omega) - \sin(j_0\omega)}{\sin(j_0\omega)}$$

$$= \frac{\sin(j\omega)}{\sin(j_0\omega)} l_{j_0} + A \frac{\cos\left(\frac{j_0}{2}\omega\right) - \cos\left(\frac{(j_0 - j)}{2}\omega\right)}{\cos\left(\frac{j_0}{2}\omega\right)}$$

$$= \frac{\sin(j\omega)}{\sin(j_0\omega)} l_{j_0} - 2A \frac{\sin\left(\frac{j_0 - 2}{2}\omega\right) \sin\left(\frac{j_0}{2}\omega\right)}{\cos\left(\frac{j_0}{2}\omega\right)}. \quad (20)$$

The previous arguments hold for any $K \in \mathbb{N}$, but we now focus on the case $K \in \{0, \ldots, L + 1\}$ in order to prove the Proposition. We can apply (20) to
\[ j_0 = K + 2, \text{ and use the conditions } l_{K+2} = 0 \text{ and } \sum l_j = 1. \] This yields:

\[
l_j = \frac{\sin \left( \frac{K+2-j}{2} \omega \right) \sin \left( \frac{\omega}{2} \right)}{\sum_{i=1}^{K+1} \sin \left( \frac{K+2-i}{2} \omega \right) \sin \left( \frac{i}{2} \omega \right)} - \frac{\cos \left( \frac{K+2}{2} - j \omega \right) - \cos \left( \frac{K+2}{2} \omega \right)}{\sum_{i=1}^{K+1} \cos \left( \frac{K+2-i}{2} \omega \right) - \cos \left( \frac{K+2}{2} \omega \right)}. \tag{21}
\]

Notice that, if \( \alpha \in (\alpha_{L+1}, \alpha_{L}) \) and \( K \in \{0, ..., L+1\} \), then for all \( j \in \{1, ..., K+1\} \):

\[
\sin \left( \frac{K+2-j}{2} \omega \right) > 0 \text{ and } \sin \left( \frac{j}{2} \omega \right) > 0.
\]

We have now proved (16).

Let us compute \( d_0 = l_0 - l_1 + \alpha l_2 \). As the solution is symmetric, i.e. \( l_j = l_{K+2-j} \), we have that \( d_{K+1} = -d_0 \).

There is an easy way to compute \( d_0 \). Indeed, let us extend the definition (16) of \( l_j \) to \( j = -1 \), then, using the fact that the system is a part of a bi-infinite Fibonacci-type sequence (for which \( d_j = 0 \) for all \( j \in \mathbb{Z} \)), one can show that \(-\alpha l_{-1} + l_0 - l_1 + \alpha l_2 = 0 \). Then, it implies

\[
d_0 = \alpha l_{-1} = -\alpha \frac{\sin \left( \frac{K+2+1}{2} \omega \right) \sin \left( \frac{\omega}{2} \right)}{\sum_{i=1}^{K+1} \sin \left( \frac{K+2-i}{2} \omega \right) \sin \left( \frac{i}{2} \omega \right)},
\]

which finishes the proof.

\[ \square \]

**Remark 4.3.** The critical case \( \alpha = \alpha_L \) is more difficult to describe. When \( K = L \), then the conditions \( l_0 = 0 \) and \( l_{L+2} = 0 \) are equivalent, hence the solution is not unique anymore, and the set of solutions is in fact 1-dimensional. More generally, the solution is not unique as soon as \((K+2)/2\) is a multiple of \(2\pi\).

**Remark 4.4.** If \( \alpha \in (\alpha_{L+1}, \alpha_L) \) is such that \( w/\pi \) is irrational, then the solution of the system, with extra condition \( l_{K+2} = 0 \), is unique for any \( K \). Moreover, we can find infinitely many \( K \)'s such that \( l_1, ..., l_{K+1}, d_0 \) are positive and \( d_{K+1} \) is negative. Indeed, this occurs when the distance between \((K+2)\omega/2\) and \((2\mathbb{Z}+1)\pi\) is smaller than the distance between \(j\omega/2\) and \((2\mathbb{Z}+1)\pi\), for all \( j \in \{1, ..., K, K+4\} \). One can believe that by using (21) and drawing a picture of the unit circle. We refer the reader to [10] for more details.

Nevertheless, generally when \( K \geq L \), there can be more than one solution, some \( l_j \)'s can be nonpositive and \( d_0, d_{K+1} \) take arbitrary signs.

### 4.3. Associated affine medium-size system: \( K = L \)

The main purpose of this section is to prove the following Proposition and its corollary, which will be used to prove Proposition 2.1.
Let us first define the affine version of the system $(E_L)$.

Fix $L \geq 1$ and assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$, where $(\alpha_L)_{L \geq 1}$ is defined in (3). Fix also $L$ real numbers $d_j$, for $j \in \{1, \ldots, L\}$. Then, consider the following system on $(l_0, \ldots, l_{L+2})$:

$$AS(d_1, \ldots, d_L) \begin{cases} l_0 = l_{L+2} = 0 \\ d_j = -\alpha l_{j-1} + l_j - l_{j+1} + \alpha l_{j+2}, \text{ for all } j \in \{1, \ldots, L\} \\ \sum_{j=1}^{L+1} l_j = 1. \end{cases}$$

Define also the quantities:

$$d_0 := l_1 - \alpha l_2,$$
$$d_{L+1} := -\alpha l_{L+1} + l_{L+2}.$$

**Proposition 4.5.** Assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$. There exists a unique solution $(l_0, \ldots, l_{L+2})$ of $AS(d_1, \ldots, d_L)$, and there exist positive constants $c_1, \ldots, c_L$, that do not depend on $d_1, \ldots, d_L$, such that:

$$d_{L+1} = -d_0(L) - \sum_{k=1}^L c_k d_k,$$
$$d_0 = d_0(L) - \sum_{j=k}^L c_{L+1-k} d_k,$$

where $d_0(L)$ is a positive constant defined in Remark 4.2.

**Corollary 4.6.** Assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$, and that $(l_0, \ldots, l_{L+2})$ is a solution of the system:

$$l_0 = 0, \quad l_{L+2} \geq 0,$$
$$d_j = -\alpha l_{j-1} + l_j - l_{j+1} + \alpha l_{j+2}, \text{ for all } j \in \{1, \ldots, L\},$$
$$\sum_{j=1}^{L+1} l_j = 1.$$

Then the following inequality holds:

$$d_0 \geq d_0(L) - \sum_{j=k}^L c_{L+1-k} d_k.$$

**Proof of Corollary 4.6.** Define $\tilde{l}_j = l_j$ for $j \in \{0, \ldots, L+1\}$, and $\tilde{l}_{L+2} = 0$. Then, $\tilde{d}_0 = d_0$, and notice that $(\tilde{l}_0, \ldots, \tilde{l}_{L+2})$ is a solution of $AS(d_1, \ldots, d_{L-1}, d_L - \alpha l_{L+2})$, hence

$$d_0 = d_0(L) - \sum_{j=k}^L c_{L+1-k} d_k + \alpha c_1 l_{L+2},$$

which enables us to conclude, using that $l_{L+2} \geq 0$. \qed
**Proof of Proposition 4.5.** First, notice that the matrix associated to the system $A_S(d_1, ..., d_L)$ can be written as:

$$M := \begin{pmatrix}
1 & 0 & \ldots & \ldots & \ldots & \ldots & 0 \\
0 & \ldots & \ldots & \ldots & \ldots & \ldots & 0 \\
0 & 1 & \ldots & \ldots & \ldots & \ldots & 1 \\
-\alpha & 1 & -1 & \alpha & 0 & \ldots & 0 \\
\ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\
0 & \ldots & 0 & -\alpha & 1 & -1 & \alpha \\
\end{pmatrix},$$

where the size of $M$ is $(L + 3)^2$, and $A_S(d_1, ..., d_L)$ is then re-written as:

$$M \begin{pmatrix}
l_0 \\
l_1 \\
l_{L+2} \\
\end{pmatrix} = \begin{pmatrix}
0 \\
0 \\
1 \\
\ldots \\
d_1 \\
\ldots \\
d_L \\
\end{pmatrix}.$$

By Proposition 4.1, there exists a unique solution to $(E_L)$ with $l_{L+2} = 0$, which is equivalent to $A_S(0, ..., 0)$. Therefore $M$ has a nonzero determinant, thus it is invertible.

Now, we first want to prove that, for some constants $c_1, ..., c_L$,

$$d_{L+1} = -d_0(L) - \sum_{k=1}^{L} c_k d_k,$$

which, by symmetry, will imply:

$$d_0 = d_0(L) - \sum_{j=k}^{L} c_{L+1-k} d_k,$$

and we will then prove that these constants are positive. Notice that

$$d_{L+1} = -\alpha l_L + l_{L+1} = \begin{pmatrix}
0 \\
0 \\
1 \\
\ldots \\
d_L \\
\end{pmatrix} M^{-1} \begin{pmatrix}
0 \\
0 \\
1 \\
\ldots \\
d_L \\
\end{pmatrix} = \begin{pmatrix}
0 \\
0 \\
-\alpha \\
\ldots \\
0 \\
\end{pmatrix} M^{-1} \left( v_3 + \sum_{k=1}^{L} \frac{d_k v_{3+k}}{v_3} \right),$$
where \((v_k)_k\) is the canonical basis of \(\mathbb{R}^{L+3}\). Then, using Proposition 4.1 and the notations of Remark 4.2, the vector \(M^{-1}v_3\) is the solution to \((E_L)\) with \(l_{L+2} = 0\), which yields

\[
d_0(L) = - (0 \ldots 0 -\alpha 1 0) M^{-1}v_3,
\]

and we prove (22) by defining, for all \(k \in \{1, \ldots, L\}\),

\[
c_k = - (0 \ldots 0 -\alpha 1 0) M^{-1}v_{3+k}.
\]

It remains to prove that, for all \(k \in \{1, \ldots, L\}\), \(c_k > 0\). Remind that these constants do not depend on \(d_1, \ldots, d_L\). We proceed by induction on \(k = 1, \ldots, L\).

First, for \(k = 1\), choose \(d_2 = \ldots = d_L = 0\), and instead of fixing \(d_1\) let us fix \(l_1 = 0\). Then, the shifted vector \((\tilde{l}_0, \ldots, \tilde{l}_{(L-1)+2}) := (l_1, \ldots, l_{L+2})\) is the unique solution of \((E_{L-1})\) with \(\tilde{l}_{(L-1)+2} = 0\). Therefore, using Proposition 4.1 and the notations of Remark 4.2, the solution is unique, \(d_1 = d_0(L-1) < 0\) and \(d_{L+1} = -d_0(L-1) > 0\). On the other hand, (22) implies that \(c_1 = (-d_0(L) - d_{L+1})/d_1 > 0\), which finishes the case \(k = 1\).

Now, assume that, for some \(k \in \{2, \ldots, L\}\), \(c_1, \ldots, c_{k-1} > 0\), and let us prove that \(c_k > 0\). As previously, fix \(d_{k+1} = \ldots = d_L = 0\) (except if \(k = L\)), and fix \(l_1 = \ldots = l_k = 0\). Then the shifted vector \((\tilde{l}_0, \ldots, \tilde{l}_{(L-k)+2}) := (l_k, \ldots, l_{L+2})\) is the unique solution of \((E_{L-k})\) with \(\tilde{l}_{(L-k)+2} = 0\). Thus, \(d_1 = \ldots = d_{k-2} = 0\) (if \(k \geq 3\)), \(d_{k-1} = \alpha l_{k+1} > 0\), \(d_k = d_0(L-k) < 0\) and \(d_{L+1} = -d_0(L-k) > 0\). On the other hand, (22) implies that \(c_k = (-d_0(L) - d_{L+1} - c_{k-1}d_{k-1})/d_k > 0\), which finishes the proof.

\[\square\]

### 4.4. Non-negative solutions of the large-size system, i.e. \(K \geq L\), and proof of Lemma 2.3

Recall the definition of the system \((E_K)\) introduced in Section 4.1. When \(K \geq L\), as it is noticed in Remarks 4.3 and 4.4, the set of solutions can be 1-dimensional, and \textit{a priori} we cannot determine the signs of \(d_0\) nor \(d_{K+1}\).

But, the following result, which implies Lemma 2.3, is helpful in order to understand the behavior of the solutions, even without uniqueness.

**Proposition 4.7.** (i) Assume that \(\alpha \in (\alpha_{L+1}, \alpha_L)\) and \(K \geq L\). Then, if some real-valued vector \((l_0, \ldots, l_{K+2})\) satisfies \((E_K)\) and if \(l_1, \ldots, l_{K+2} \geq 0\), then \(d_0 \geq c(K) > 0\), where \(c(K)\) is a positive constant depending only on \(\alpha\) and \(K\). It implies that if \(l_{K+2} = 0\), then, by symmetry, we have \(d_{K+1} \leq -c(K)\).

(ii) Assume that \(\alpha \in (\alpha_{L+1}, \alpha_L]\) If \(K \geq L\) and if \((l_0, \ldots, l_{K+2})\) satisfies \((E_K)\), then:

\[
l_{L+2} - \alpha l_{L+1} = - \frac{\sin(L+2\omega)}{\sin(2\omega)} l_1 + 2\alpha \frac{\cos(\frac{L+3}{2}\omega)}{\sin(\frac{L+3}{2}\omega)} l_{L+1}.
\]  

Moreover, if \(\alpha \in (\alpha_{L+1}, \alpha_L)\) and if \(l_1, \ldots, l_{K+2} \geq 0\), then \(l_{L+2} - \alpha l_{L+1} < -c(K)\), where \(c(K)\) is the same positive constant as in (i).
Proof. Let us prove the first point:

(i) Remind that $\alpha \in (\alpha_{L+1}, \alpha_L)$. Let us first prove that $\sum_{k=1}^{L+1} l_k > c$, for some positive constant $c$.
Recall that $l_0 = 0$ and $d_1 = ... = d_K = 0$. If $l_1 < c$ and $l_2 < c$, we can prove, by induction, that

$$l_j \leq 6^{j-1} c$$

for all $j \in \{1, ..., K+2\}$, which implies, as soon as $c$ is small enough, that $\sum_{j=1}^{K+1} l_j < 1$ which contradicts the weight condition. In order to prove (24) by induction, recall that $\alpha > 1/3$ and notice that, for all $j \in \{2, ..., K+1\}$, $d_{j-1} = -\alpha l_{j-2} + l_{j-1} - l_j + \alpha l_{j+1} = 0$ and $l_{j-1} \geq 0$, which implies that

$$l_{j+1} \leq l_{j-2} + l_j / \alpha.$$  

Now, define, for all $j \in \{0, ..., L+2\}$,

$$\tilde{l}_j := \frac{l_j}{\sum_{k=1}^{L+1} l_k}.$$  

Now, we use Corollary 4.6 with $(\tilde{l}_0, ..., \tilde{l}_{L+2})$, which enables us to conclude:

$$d_0 \geq d_0(L) \times \sum_{k=1}^{L+1} l_k > d_0(L) \times c > 0.$$  

(ii) Here, we assume $\alpha \in (\alpha_{L+1}, \alpha_L]$. To prove (ii), we consider the system $(E_K)$, together with the conditions $l_1, ..., l_{K+2} \geq 0$ and let $l_{L+1}$ be a parameter in order to explicit the $l_j$’s in terms of $l_{L+1}$.

We can use the arguments at the beginning of the proof of Proposition 4.1. In particular, noticing that $\sin((L+1)\omega) \neq 0$, we can apply (20) to $j_0 = L + 1$, which yields, for all $j \in \{1, ..., K+2\}$, and for some constant $A$,

$$l_j = \frac{\sin(j_0 \omega)}{\sin((L+1)\omega)} l_{L+1} - 2A \frac{\sin(L+1-l_j) \sin(\frac{\omega}{2})}{\cos(\frac{L+1}{2} \omega)}.$$  

Then, we can explicit $A$ in terms of $l_{L+1}$ and $l_1$:

$$2A \frac{\sin(\frac{\omega}{2}) \sin(\frac{\omega}{2})}{\cos(\frac{L+1}{2} \omega)} = \frac{\sin(\omega)}{\sin((L+1)\omega)} l_{L+1} - l_1,$$  

and compute

$$l_{L+2} - \alpha l_{L+1} = \left(\frac{\sin((L+2)\omega)}{\sin((L+1)\omega)} - \alpha\right) l_{L+1} + 2A \frac{\sin(\frac{L+2}{2} \omega) \sin(\frac{\omega}{2})}{\cos(\frac{L+1}{2} \omega)} l_{L+1}$$

$$= \left(\frac{\sin((L+2)\omega)}{\sin((L+1)\omega)} - \alpha + \frac{\sin(\omega) \sin(\frac{L+2}{2} \omega)}{\sin((L+1)\omega) \sin(\frac{\omega}{2})}\right) l_{L+1}$$

$$- \frac{\sin(\frac{L+2}{2} \omega)}{\sin(\frac{\omega}{2})} l_1.$$
Now, in order to prove (23), define $E$ such that:
\[
\frac{\sin((L + 2)\omega)}{\sin((L + 1)\omega)} - \alpha + \frac{\sin(\omega) \sin\left(\frac{L+2}{2}\omega\right)}{\sin((L + 1)\omega) \sin\left(\frac{L}{2}\omega\right)} = -\frac{\alpha E}{4 \sin\left(\frac{L}{2}\omega\right) \sin((L + 1)\omega)},
\]
then, using that $\alpha^{-1} = 1 + 2 \cos(\omega)$ and the exponential forms of $\sin$ and $\cos$, we have:
\[
E = (e^{i\frac{L}{2}\omega} - e^{-i\frac{L}{2}\omega})(e^{i(L+2)\omega} - e^{-i(L+2)\omega})(1 + e^{i\omega} + e^{-i\omega}) \\
- (e^{i\frac{L}{2}\omega} - e^{-i\frac{L}{2}\omega})(e^{i(L+1)\omega} - e^{-i(L+1)\omega}) \\
+ (e^{i\frac{L+2}{2}\omega} - e^{-i\frac{L+2}{2}\omega})(e^{i\omega} - e^{-i\omega})(1 + e^{i\omega} + e^{-i\omega}) \\
= e^{\frac{3}{2}L\omega}(e^{i2\omega} + e^{i3\omega}) + e^{-\frac{3}{2}L\omega}(e^{-i2\omega} + e^{-i3\omega}) \\
- e^{\frac{5}{2}L\omega}(1 + e^{-i\omega}) - e^{-\frac{5}{2}L\omega}(1 + e^{i\omega}) \\
= 4 \cos\left(\frac{\omega}{2}\right)\left(\cos\left(\frac{3}{2}L + \frac{5}{2}\right)\omega\right) - \cos\left(\frac{L - 1}{2}\omega\right) \\
= -8 \cos\left(\frac{\omega}{2}\right) \sin\left(\frac{L + 3}{2}\omega\right) \sin\left((L + 1)\omega\right),
\]
which proves (23).

Let us prove the second part of (ii). Assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$, and recall that it is equivalent to $2\pi/(L + 3) < \omega < 2\pi/(L + 2)$. Here, we use the notation $\text{Cst}(\alpha, K)$ to denote a positive constant, depending on $\alpha$ and $K$, which can be different from line to line or between two (in-)equalities.

Let us show that, there exists a constant $\tilde{c}$ such that $l_1 + l_{L+1} \geq \tilde{c}$. It will imply the conclusion, using (23), i.e. $l_{L+2} - \alpha l_{L+1} \leq -\text{Cst}(\alpha, K)(l_1 + l_{L+1}) \leq -\text{Cst}(\alpha, K)$.

By contradiction, assume that $l_1 + l_{L+1} < \tilde{c}$, then we obviously have $l_1 < \tilde{c}$ and $l_{L+1} < \tilde{c}$. The formula (26) implies that
\[
0 \leq 2A < \text{Cst}(\alpha, K) \times \tilde{c},
\]
then (25) implies that
\[
\sum_{j=1}^{K+1} l_j < (K + 1)\text{Cst}(\alpha, K) \times \tilde{c}.
\]
Now $\tilde{c}$ small enough would imply $\sum_{j=1}^{K+1} l_j < 1$, and thus contradicts the weight condition. \qed

5. The walk has finite range: Proof of Proposition 2.1

In the section, we want to prove Proposition 2.1, which states that the walk has finite range.
The general strategy of the proof is inspired by the one of [15], rewritten in [17]. This proof is quite simple, making use of Corollary 4.6.

**Proof.** Let us prove that there exists a constant \( p > 0 \) such that, for all \( x \in \mathbb{Z} \) such that \( x < -L - 1 \), if the walker visits \( x + L + 1 \), then, with probability at least \( p \), the walker does not visit the site \( x - 1 \), i.e.

\[
\mathbb{P} (x - 1 \in R | x + L + 1 \in R) < 1 - p.
\]

Note that \( p \) will not depend on \( x \).

This will imply that

\[
\mathbb{P} (\inf R = -\infty) = 0.
\]

Then, the symmetric argument will hold and give us the conclusion.

For all \( y \in \mathbb{Z} \) and \( m \in \mathbb{N} \), let \( u_m(y) \) be the first time \( k \) such that \( Z_k(y) = m \).

If \( Z_\infty(y) < m \), then \( u_m(y) = +\infty \).

Now fix \( x \in \mathbb{Z} \) such that \( x < -L - 1 \). For all \( m \in \mathbb{N} \), we have

\[
\mathbb{P} (X_{k+1} = x + L + 1 | \mathcal{F}_k) \geq \frac{\mathbb{1}_{\{u_m(x+L)=k,Z_k(x+L-1)=0\}}}{1 + e^{2(2m-1)\beta}}.
\]

This implies that, for all \( m \in \mathbb{N} \),

\[
\mathbb{P} (Z_{u_m(x+L)}(x + L - 1) = 0 | \mathcal{F}_{u_1(x+L)}) \geq \mathbb{1}_{\{u_1(x+L)<\infty\}} \varepsilon_1,
\]

where \( \varepsilon_1 := \varepsilon_1(m) \) is a constant depending on \( m \), but not on \( x \).

From now on, we work on the event \( \{Z_{u_m(x+L)}(x + L - 1) = 0\} \). Notice that, on this event, for any \( n \in \mathbb{N} \), \( u_n(x) \geq u_1(x) > u_m(x + L) \).

Define, for all \( k \in \mathbb{N} \), the time spent in the interval \([x, x + L + 1]\), i.e.

\[
l^{(x)}_k := l_k(x) + l_k(x + 1) + \ldots + l_k(x + L + 1),
\]

and notice that \( l^{(x)}_{u_m(x+L)} = 2m - 1 \).

Fix \( \varepsilon_2 > 0 \), and define, for all \( n \in \mathbb{N} \), the event \( U_n \) which is such that the walker perform an upstream jump on \([x + 1, \ldots, x + L]\) of intensity at least \( \varepsilon_2 \) between the times \( u_m(x + L) \) and \( u_n(x) \), i.e. there exist \( k \in [u_m(x + L), u_n(x)] \) and \( j \in \{1, \ldots, L\} \) such that \( \Delta_k(x+j)/l^{(x)}_k > \varepsilon_2 \), \( X_k = j \) and \( X_{k+1} = j - 1 \). If we define \( u_\infty(x) = \infty \), then \( \bigcup_n U_n = U_\infty \).

Now, notice that, on the event \( \{Z_{u_m(x+L)}(x + L - 1) = 0\} \), we have:

\[
\{Z_\infty(x - 1) > 0\} \subset \bigcup_{n=1}^{\infty} \{u_1(x - 1) = u_n(x) + 1\} \cap \{u_n(x) < \infty\}
\]

\[
\subset \left( \bigcup_{n=1}^{\infty} \{u_1(x - 1) = u_n(x) + 1\} \cap \{u_n(x) < \infty\} \right) \cap U_n^c \cup U_\infty.
\]

(27)
It is easy to upper-bound the probability of $U_\infty$, then let us focus on the other union of events.

Until the conclusion of the proof, fix $n \in \mathbb{N}$, assume that $u_n(x) < +\infty$ and $l_{u_n}(x) = 0$, which is necessary to have $u_1(x - 1) = u_n(x) + 1$. Moreover, assume that $U_n^c$ holds and let us show that, at time $u_n(x)$, the stream at $x$ is strongly positive, thus the probability for the walker to jump on $x - 1$ is small.

For $j \in \{1, \ldots, L\}$, let $k_j$ the last time before $u_n(x)$ such that $X_{k_j} = x + j$. Then, as $X_{k_j+1} = x + j - 1$ and $U_n^c$ holds, we have $\Delta_{k_j}(x + j)/l_{u_n}^{(x)} \leq \varepsilon_2$. Therefore, we have that, for any $j \in \{1, \ldots, L\}$,

$$\frac{\Delta_{u_n(x)}(x + j)}{l_{u_n}^{(x)}} = \frac{-\alpha \left(l_{u_n}(x)(x + j - 1) - l_{k_j}(x + j - 1)\right) + \Delta_{k_j}(x + j) + 1}{l_{u_n}^{(x)}} \leq 2\varepsilon_2,$$

where the inequality holds as soon as we choose $m > (1 + \varepsilon_2)/(2\varepsilon_2)$.

Moreover, recall that $l_{u_n}(x)(x) = 0$ and notice that

$$\sum_{j=1}^{L+1} \frac{l_{u_n}(x)(x + j)}{l_{u_n}^{(x)}} = 1.$$

Therefore, using Corollary 4.6, with $l_j := l_{u_n(x)}(x+j)/l_{u_n}(x)$ for all $j \in \{0, \ldots, L+2\}$, we obtain:

$$\frac{\Delta_{u_n(x)}(x)}{l_{u_n}^{(x)}} \geq d_0(L) - \sum_{k=1}^{L} \frac{\Delta_{u_n(x)}(x + k)}{l_{u_n}^{(x)}} c_k$$

$$\geq d_0(L) - 2\varepsilon_2 \sum_{k=1}^{L} c_k > \frac{d_0(L)}{2} > 0,$$

as soon as $\varepsilon_2$ is small enough, depending only on the constants $c_k$’s and $d_0(L)$, where the $c_k$’s are positive constants defined in Proposition 4.5 and $d_0(L)$ is defined in Remark 4.2.

Using (27) and using that $l_{u_m(x+L)} = 2m - 1$, we are finally able to conclude, as soon as $m$ is large enough, as we have:

$$\mathbb{P} \left( Z_\infty(x - 1) > 0 \mid \mathcal{F}_{u_m(x+L)} \right) \mathbb{I}\{Z_{u_m(x+L)}(x+L-1) = 0\} \leq \sum_{k=l_{u_m}(x+L)}^{+\infty} e^{-2\beta d_0(L)/2} k + \sum_{k=l_{u_m}(x+L)}^{+\infty} e^{-2\beta \varepsilon_2 k}.$$
6. Asymptotic streams

Given $L \geq 1$, assume that $\alpha \in (\alpha_{L+1}, \alpha_L)$ and fix $x \in \mathbb{Z}$ and $K \in \mathbb{N}$. The goal is here to prove Proposition 2.2 in Section 6.1, and Lemma 2.4 in Section 6.2.

6.1. Proof of Proposition 2.2

Remind that Proposition 2.2 states that, almost surely, we have:

$$\{R' = \{x, \ldots, x+K+1\} \subset \bigcap_{j=x+1}^{x+K} \left\{ \lim_{k \to +\infty} \frac{\Delta_k(j)}{k} = 0 \right\}. \quad (28)$$

Proposition 2.2 extends to general $K \in \mathbb{N}$ the result of Erschler, Tóth and Werner in [10], initially proved for $K < L+1$. Its proof is mainly combinatorial.

Let us first state and prove two Lemmas that will be used several times to prove Proposition 2.2.

The only probabilistic tool of the proof is Borel-Cantelli Lemma, which is used to prove the following result.

**Lemma 6.1.** There exist two random times $N_1$ and $N_2$ such that:

(i) For all $j \in \mathbb{Z}$, and for all $k \geq N_1$, if $\Delta_k(j)/k \geq \varepsilon$ and $X_k = j$, then $X_{k+1} = j+1$, and if $\Delta_k(j)/k \leq -\varepsilon$ and $X_k = j$, then $X_{k+1} = j-1$;

(ii) For all $k \geq N_2$, for all $j \in \mathbb{Z}$, if $X_k < j$, then $\Delta_k(j)/k < 3\varepsilon/2$ and if $X_k > j$, then $\Delta_k(j)/k > -3\varepsilon/2$.

**Proof.** Let us prove the first point.

Recall that, for all $j \in \mathbb{Z}$, we have

$$\mathbb{P}\left( X_{k+1} = X_k + 1 \mid \mathcal{F}_k \right) = \frac{1}{1 + e^{-2\beta \Delta_k(X_k)}},$$

which yields:

$$\mathbb{P}\left( X_k = j, X_{k+1} = j+1, \frac{\Delta_k(j)}{k} \leq -\varepsilon \mid \mathcal{F}_k \right) \leq \frac{\mathbb{I}(X_k=j)}{1 + e^{2\beta \varepsilon k}}.$$

Therefore, we have that

$$\mathbb{P}\left( \bigcup_{j \in \mathbb{Z}} \left\{ X_k = j, X_{k+1} = j \pm 1, \frac{\Delta_k(j)}{k} \geq \varepsilon \right\} \mid \mathcal{F}_k \right) \leq \frac{2}{1 + e^{2\beta \varepsilon k}},$$

which is summable. Then, by Borel-Cantelli Lemma, there exists a random $N_1 \in \mathbb{N}$ such that for all $j \in \mathbb{Z}$, and for all $k \geq N_1$, if $\Delta_k(j)/k \geq \varepsilon$ and $X_k = j$, then $X_{k+1} = j+1$, and if $\Delta_k(j)/k \leq -\varepsilon$ and $X_k = j$, then $X_{k+1} = j-1$.

Let us prove the second point of the Lemma. Let $N_2$ be the smallest integer such that $N_2 > 2(1+\alpha)N_1/3\varepsilon > N_1$ and $N_2 > 4/\varepsilon$. 
Assume that $k \geq N_2$ and $X_k < j$. Recall that, by definition of $N_1$, the walker cannot jump from $j$ to $j-1$ at some time $k \geq N_1$ if $\Delta_k(j)/k \geq \varepsilon$. Recall also the definition of the local time at site $j$ and at time $k$:

$$\Delta_k(j) = -\alpha l_k(j-1) + l_k(j) - l_k(j+1) + \alpha l_k(j+2).$$

First, if the walker has not visited $j$ between $N_1$ and $k$, then $\Delta_k(j) \leq \Delta_{N_1}(j) \leq N_1 \times (1 + \alpha)$, hence

$$\Delta_k(j) \leq \Delta_{N_1}(j) \frac{N_1}{N_2} \times \frac{3\varepsilon}{2}.$$ 

Otherwise, let $k'$ be the last time before $k$ such that $X_{k'} = j$. Then $X_{k'+1} = j-1$, and therefore $\Delta_{k'}(j)/k' < \varepsilon$. Note that $\Delta_k(j) \leq \Delta_{k'}(j) + 1$, hence

$$\frac{\Delta_k(j)}{k} < \frac{3\varepsilon}{2},$$

which proves the first part of $(ii)$ and the second part is proved by the symmetric argument.

Recall that $L \geq 1$, $\alpha \in (\alpha_{L+1}, \alpha_L)$, $K \in \mathbb{N}$ are fixed. The following Lemma uses the results of Section 4 in order to describe the evolutions of the local times at two sites when the wall is stuck between them.

**Lemma 6.2.** Fix $i_1, i_2 \in \mathbb{Z}$ such that $0 < i_2 - i_1 < K$. Fix two times $k$ and $k'$ such that $k < k'$. Assume that the walk remains in $\{i_1, ..., i_2+1\}$ between the time $k$ and $k'$ and define

$$\delta_{\text{max}} := \max \left\{ \frac{\Delta_n(i)}{n} : n \in [k, k'], i \in \{i_1+1, ..., i_2\} \right\}.$$

Then, there exist two positive constants $d$ and $C_1$, depending on $\alpha$ and $K$, such that

$$\Delta_{k'}(i_1 + m(i_2 - i_1)) \geq \Delta_k(i_1 + m(i_2 - i_1)) \frac{k}{k'} \times \frac{k}{k'} + d \times \frac{k' - k}{k'} - 2C_1\delta_{\text{max}},$$

$$\Delta_{k'}(i_2 + 1 - m(i_2 - i_1)) < \Delta_k(i_2 + 1 - m(i_2 - i_1)) \frac{k}{k'} \times \frac{k}{k'} - d \times \frac{k' - k}{k'} + 2C_1\delta_{\text{max}},$$

where $m(k) := (k + 1)I_{\{k \geq L\}}$, for all $k \in \mathbb{N}$.

Before proving this result, let us emphasize two simple consequences. First,
notice that
\[
\frac{\Delta_{k'}(i_1 + m(i_2 - i_1))}{k'} > \min \left( \frac{\Delta_k(i_1 + m(i_2 - i_1))}{k}, d \right) - 2C_1\delta_{\text{max}},
\]
\[
\frac{\Delta_{k'}(i_2 + 1 - m(i_2 - i_1))}{k'} < \max \left( \frac{\Delta_k(i_2 + 1 - m(i_2 - i_1))}{k}, -d \right) + 2C_1\delta_{\text{max}}.
\]
Secondly, if
\[
\frac{k' - k}{k} \geq \frac{2C_1\delta_{\text{max}}}{d},
\]
then
\[
\frac{\Delta_{k'}(i_1 + m(i_2 - i_1))}{k'} > \frac{\Delta_k(i_1 + m(i_2 - i_1))}{k} \times \frac{k}{k'},
\]
\[
\frac{\Delta_{k'}(i_2 + 1 - m(i_2 - i_1))}{k'} < \frac{\Delta_k(i_2 + 1 - m(i_2 - i_1))}{k} \times \frac{k}{k'}.
\]

Proof. Define
\[
\tilde{l}_i = \frac{l_{k'}(i_1 + i) - l_k(i_1 + i)}{k' - k}, \text{ for all } i \in \{0, ..., i_2 - i_1 + 2\},
\]
and \(\tilde{d}_i = -\alpha \tilde{l}_{i-1} + \tilde{l}_i - \tilde{l}_{i+1} + \alpha \tilde{l}_{i+2}, \text{ for all } i \in \{1, ..., i_2 - i_1\}\).
Thus,
\[
\tilde{l}_0 = \tilde{l}_{i_2 - i_1 + 2} = 0, \sum_{i=1}^{i_2 - i_1 + 1} \tilde{l}_i = 1 \text{ and } |\tilde{d}_i| < 2\delta_{\text{max}} \times \frac{k'}{k' - k}, \forall i \in \{1, ..., i_2 - i_1\}.
\]
Define also \(\tilde{d}_0 = -\tilde{l}_1 + \alpha \tilde{l}_2 \text{ and } \tilde{d}_{i_2 - i_1 + 1} = -\alpha \tilde{l}_{i_2} + \tilde{l}_{i_2 + 1}\).
Recall the notations \(d_0(K')\) and \(d_{K' + 1}(K')\) defined in Remark 4.2, \(c(K)\) defined in Proposition 4.7 and define
\[
d := \min \{ |d_0(K')|, d_{K' + 1}(K'), K' = 1, ..., L - 1, c(K) \} > 0. \quad (29)
\]
Let us consider \((\tilde{l}_i)\) as a perturbed solution of the linear system \((E_{i_2 - i_1})\) defined and described in Section 4. Then we have to distinguish two cases: \(j \leq L - 1\) and \(j \geq L\). Indeed, if \(i_2 - i_1 \leq L - 1\), using Proposition 4.1 and using that \((E_{i_2 - i_1})\) is a linear system, there exists a positive constant \(C_1\) such that
\[
\tilde{d}_0 < -d + C_1 \times 2\delta_{\text{max}} \times \frac{k'}{k' - k},
\]
\[
\tilde{d}_{i_2 - i_1 + 1} > d - C_1 \times 2\delta_{\text{max}} \times \frac{k'}{k' - k}.
\]
Otherwise, if \( j \geq L \), using Proposition 4.7, we have similarly
\[
\tilde{d}_0 > d - C_1 \times 2\delta_{\max} \times \frac{k'}{k' - k},
\]
\[
\tilde{d}_{i_{2i+1}} < -d + C_1 \times 2\delta_{\max} \times \frac{k'}{k' - k}.
\]
We can conclude by multiplying these quantities by \((k' - k)/k'\) and noticing that, for \( i \in \{0, i_2 - i_1 + 1\}\),
\[
\tilde{d}_i := \frac{\Delta_{k'}(i_1 + i) - \Delta_k(i_1 + i)}{k' - k}.
\]

Let us now prove Proposition 2.2, i.e. (28).

**Proof of Proposition 2.2.** We assume throughout the proof that the probability event \( \{ R' = \{ x, ..., x + K + 1 \} \} \) holds.

Let us show that there exists a constant \( M := M(\alpha, d, C_1) \) such that, for all \( j \in \{1, ..., K\} \), for all \( \varepsilon > 0 \) small enough, we have
\[
\frac{\Delta_k(x + j)}{k} > -3\varepsilon M^{\frac{j(j-1)}{2}}
\]
as soon as \( k \) is large enough. Then the symmetric argument will hold and enable us to conclude. Note that, in fact, the constant \( M \) depends only on \( \alpha \) and \( K \), since \( d \) and \( C_1 \) depend only on \( \alpha \) and \( K \).

For reasons that will appear later, we can choose \( M \) and \( \varepsilon \) such that
\[
M > \frac{3 \times (d + 8C_1)}{d} \times (3 + \alpha) \text{ and } \varepsilon < \frac{2(1 + \alpha) \land d}{3MK(K+1)}. \tag{31}
\]

As \( R' = \{ x, ..., x + K + 1 \} \), there exists a random \( N_3 \in \mathbb{N} \) such that \( Z_{\infty}(i) = Z_{N_3}(i) \) if \( i \notin R' \).

Finally, recalling the definitions of \( N_1 \) and \( N_2 \) in Lemma 6.1, let us define the time \( N := \max(N_1, N_2, N_3, (1 + \alpha)/\varepsilon) \). We work at large times \( k \geq N \), and the rest of the proof is only logical.

By definition of \( R' \), there exists \( k_1 \geq N \) such that \( X_{k_1} = x + K + 1 \). Therefore, using Lemma 6.1, for all \( j \in \{1, ..., K\} \),
\[
\frac{\Delta_{k_1}(x + j)}{k_1} > -2\varepsilon.
\]

Let us prove by induction on \( j = 1, ..., K \), that, for all \( k \geq k_1 \), we have
\[
\frac{\Delta_k(x + j)}{k} > -3\varepsilon M^{\frac{j(j-1)}{2}}.
\]
(i) The base case: \( j = 1 \). Assume by contradiction that there exists \( \hat{k} \geq k_1 \) such that
\[
\frac{\Delta_{\hat{k}}(x+1)}{\hat{k}} \leq -3\varepsilon,
\]
and define:
\[
\tilde{k} := \max \left\{ k \in [k_1, \hat{k}] : \frac{\Delta_k(x+1)}{k} > -2\varepsilon \right\}.
\]
Hence, using Lemma 6.1 between \( \tilde{k} \) and \( \hat{k} \), the walk remains left-hand from \( x+1 \) and thus confined to \( \{x, x+1\} \), therefore
\[
\frac{\Delta_{\hat{k}}(x+1)}{\hat{k}} = \frac{\Delta_{\tilde{k}}(x+1) + (\hat{k} - \tilde{k})}{\hat{k} + (\hat{k} - \tilde{k})} > -2\varepsilon,
\]
which contradicts our assumption.

(ii) Induction step: Assume that \( j \in \{1, \ldots, K-1\} \), and that, for all \( i \in \{1, \ldots, j\} \) and \( k \geq k_1 \), we have:
\[
\frac{\Delta_k(x+i)}{k} > -3\varepsilon M^\frac{i(i-1)}{2}.
\]
We want to show that, for all \( k \geq k_1 \),
\[
\frac{\Delta_k(x+j+1)}{k} > -3\varepsilon M^\frac{j(j+1)}{2}.
\]
By contradiction, assume that there exists a finite integer \( k^* \) such that
\[
k^* := \min \left\{ k \geq k_1 : \frac{\Delta_k(x+j+1)}{k} \leq -3\varepsilon M^\frac{j(j+1)}{2} \right\} < \infty.
\]
By definition of \( R' \), there exists \( k_2 > k^* \) such that \( X_{k_2} = x + K + 1 \), and, using Lemma 6.1,
\[
\frac{\Delta_{k_2}(x+j+1)}{k_2} > -2\varepsilon.
\]
Define the following times:
\[
k := \max \left\{ k_1 \leq k \leq k^* : \frac{\Delta_k(x+j+1)}{k} > -3\varepsilon M^\frac{j(j+1)}{2} \right\}, \quad (34)
\]
\[
\tilde{k} := \min \left\{ k^* \leq k \leq k_2 : \frac{\Delta_k(x+j+1)}{k} > -3\varepsilon M^\frac{j(j+1)}{2} \right\}. \quad (35)
\]
Note that the definitions of \( k_1, k, k^*, \tilde{k} \) and \( k_2 \) will be kept throughout the proof. All other notations used to define some other times change from part to part.

We need the following lemma, which will be shown right after this proof.
Lemma 6.3. Under the previous assumptions, in particular assuming (32) and (33), for all \(i \in \{1, \ldots, j\}\), and for all \(k\) such that \(k \leq k \leq \bar{k}\), we have:

\[
\left| \frac{\Delta_k(x+i)}{k} \right| < 3\varepsilon M \frac{(j+1)}{2} (j-i).
\]

The strategy to prove this Lemma will be the same as the one to conclude the on-going proof.

Assuming that (33) holds, the times \(\bar{k}, k^*, \bar{k}\) are key-times at which we know the behavior of the local stream at \(x + j + 1\), see Figure 2. Using Lemma 6.3 and Lemma 6.2, we will compare the evolution of the local times on the interval \(\{x, \ldots, x + j + 1\}\) to the solution of the system \((E_j)\), defined in Section 4.1. This will enable us to emphasize some contradictions about the evolution of the local streams and conclude that (33) cannot hold.

Let us distinguish between two cases: \(j \leq L - 1\) and \(j \geq L\).

First, assume that \(j \leq L - 1\). By Lemma 6.1, the walker remains left-hand from \(x + j + 1\) on \([\bar{k}, k^*]\), thus the walk is confined to \(\{x, \ldots, x + j + 1\}\) on this time-span.

Moreover, notice that, at each time-step, \(\Delta_k(x+j+1)\) varies by \(0, \pm 1\) or \(\pm \alpha\).

Using the definitions (34) of \(\bar{k}\) and (33) of \(k^*\), and using (31), this yields:

\[
k^* - \bar{k} > \frac{1}{1 + \alpha} \times \frac{-\Delta_{k^*}(x+j+1) + \Delta_k(x+j+1)}{k^*}
= \frac{1}{1 + \alpha} \left(3\varepsilon M \frac{(j+1)}{2} - 3\varepsilon M \frac{(j+1)}{2} \right) \geq \frac{3\varepsilon M \frac{(j+1)}{2} - 1}{1 + \alpha} (M - 1)
> 6\varepsilon M \frac{(j+1)}{d} (M - 1).
\]

(36)
Hence, using Lemma 6.2 with $i_1 = x$, $i_2 = x + j$, $k = \bar{k}$ and $k' = k^*$, and using Lemma 6.3, this yields

$$\frac{\Delta_{k^*}(x + j + 1)}{k^*} > \frac{\Delta_{\bar{k}}(x + j + 1)}{\bar{k}} \times \frac{\bar{k}}{k^*} > -3\varepsilon M^{\frac{d(i+1)}{2}},$$

where we use the definition (34) of $\bar{k}$ for the last inequality. This contradicts the definition (33) of $k^*$ and concludes the first case $j \leq L - 1$.

Now, assume that $j \geq L$. Similarly, by Lemma 6.1, the walk is confined to $\{x, ..., x + j + 1\}$ on the time-span $[k^*, \bar{k}]$. Recall the definition (33) of $k^*$, (31), and that $d > 3\varepsilon M^{\frac{d(i+1)}{2}}$. Then, using Lemma 6.2 with $i_1 = x$, $i_2 = x + j$, $k = k^*$ and $k' = \bar{k}$, and using Lemma 6.3, this yields

$$\frac{\Delta_{\bar{k}}(x + j + 1)}{\bar{k}} < -3\varepsilon M^{\frac{d(i+1)}{2}} + 6C_1\varepsilon M^{\frac{d(i+1)}{2} - 1}$$

$$< -3\varepsilon M^{\frac{d(i+1)}{2}}.$$

This contradicts the definition (35) of $\bar{k}$ and finishes the second case, the induction step, and the proof of Proposition 2.2.

Proof of Lemma 6.3. By assumption (32), we know that, for all $i \in \{1, ..., j\}$ and for all $k \geq k_1$,

$$\frac{\Delta_k(x + i)}{k} > -3\varepsilon M^{\frac{d(i+1)}{2}} \geq -3\varepsilon M^{\frac{d(i+1)}{2} + (j-i)}.$$

Thus, it remains to prove that, for all $k \in [\bar{k}, k]$,

$$\frac{\Delta_k(x + i)}{k} < 3\varepsilon M^{\frac{d(i+1)}{2} + (j-i)}. \quad (37)$$

We will proceed in the same way as in the previous proof, by induction for $i = j, ..., 1$.

(i) The base case: $i = j$. Notice that $\Delta_{\bar{k}}(x+j)/\bar{k} < 2\varepsilon$ as $\Delta_{\bar{k}+1}(x+j)/(\bar{k}+1) < 0$ by definition (34) of $\bar{k}$.

Now, let us derive this result on the whole time-span $[\bar{k}, \bar{k}]$, by proving that, for all $k \in [\bar{k}, \bar{k}]$, $\Delta_k(x+j)/k < 3\varepsilon$. By contradiction, assume that there exists $\hat{k} \in (\bar{k}, \bar{k}]$, such that

$$\frac{\Delta_{\hat{k}}(x+j)}{\hat{k}} \geq 3\varepsilon,$$

and let $\tilde{k}$ the last time before $\hat{k}$ such that $\Delta_{\tilde{k}}(x+j)/\tilde{k} < 2\varepsilon$, i.e.

$$\tilde{k} := \max \left\{ k \in [\bar{k}, \bar{k}] : \frac{\Delta_k(x+j)}{k} < 2\varepsilon \right\}.$$
Thus, using Lemma 6.1, the walk is confined to \( \{ j, j+1 \} \) on the time-span \( [\hat{k}, \tilde{k}] \).

It implies
\[
\Delta_k(x+j) - \frac{\Delta_k(x+j) - (\hat{k} - \tilde{k})}{\hat{k} + (\hat{k} - \tilde{k})} < 2\varepsilon,
\]
which contradicts our assumptions.

Therefore, for all \( k \in [k, \tilde{k}] \),
\[\Delta_k(x+j) < 3\varepsilon \leq 3\varepsilon M^{\frac{j-i}{2}}.\]

(ii) The induction step: Assume that, for all \( m \in \{ i+1, ..., j \}, i \geq 1 \), and for all \( k \in [k, \tilde{k}] \),
\[
\left| \Delta_k(x+m) \right| < 3\varepsilon M^{\frac{j-i}{2} + (j-m)}.
\]

Let us prove it for \( m = i \). More precisely, using (32), it remains to prove that:
\[
\Delta_k(x+i) < 3\varepsilon M^{\frac{j-i}{2} + (j-i)}, \text{ for all } k \in [k, \tilde{k}].
\]

We will now use Lemma 6.2, distinguishing between two cases: \( j-i \leq L-1 \) and \( j-i \geq L \).

(ii.a) Assume that \( j-i \leq L-1 \).

Let us start by proving that
\[
\Delta_k(x+i) < \frac{3}{2} \varepsilon M^{\frac{j-i}{2} + (j-i)},
\]
and we will then prove (39) by deriving this property on the whole time-span \( [k, \tilde{k}] \).

By contradiction, assume that
\[\Delta_k(x+i) \geq \frac{3}{2} \varepsilon M^{\frac{j-i}{2} + (j-i)}.
\]

Note that, using Lemma 6.1 and recalling the definition (34) of \( \hat{k} \) and (35) of \( \tilde{k} \), the walk is confined to \( \{ x+i, ..., x+j+1 \} \) as long as \( \Delta_k(x+i)/k \geq \varepsilon \) and \( k \leq \tilde{k} \). As \( |\Delta_{k+1}(x+i) - \Delta_k(x+i)| \leq 1 + \alpha, \) the walk is confined at least until the time \( \tilde{k} \), which is the integer defined by
\[
\tilde{k} := \left\lfloor \frac{1 + \alpha + \frac{2}{\varepsilon} M^{\frac{j-i}{2} + (j-i)}}{1 + \alpha + \varepsilon} \right\rfloor .
\]

where \( \lfloor . \rfloor \) is the floor function. Using (36), using that \( k > 1/\varepsilon \) and \( d < 1 \), let us prove that \( \tilde{k} \in (k, k^*) \):
\[
k^* - \tilde{k} = (k^* - k) - (\hat{k} - k) > k \left( 6C_1\varepsilon M^{\frac{j-i}{2} - 1} - \frac{3}{2} \varepsilon M^{\frac{j-i+1}{2}} \right) + \varepsilon k - 1 > 0.
\]
Hence, using Lemma 6.1, the walk is confined to \( \{x + i, \ldots, x + j + 1\} \) on the time-span \([\tilde{k}, \bar{k}]\). Moreover, using (41) and (31),

\[
\frac{\hat{k} - k}{k} > \frac{\frac{3}{2} \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - \varepsilon}{1 + \alpha + \frac{3}{2} \varepsilon M^{\frac{i(i-1)}{2}} + (j-i)} > \frac{\frac{3}{2} \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - \varepsilon}{2(1 + \alpha)} > \frac{6C_1 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - 1}{d} \left( M \times \left( \frac{M \times d}{4C_1(1 + \alpha)} - \frac{d}{12C_1(1 + \alpha)} \right) \right) > \frac{6C_1 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - 1}{d}.
\]

Thus, using Lemma 6.2 with \( i_1 = x + i, i_2 = x + j, k = \tilde{k} \) and \( k' = \bar{k} \), and using the hypothesis (38), we obtain

\[
\frac{\Delta_k(x + j + 1)}{k} > \frac{\Delta_k(x + j + 1)}{k} \times \frac{k}{k} > -3 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i),
\]

which contradicts the definitions (34) of \( \bar{k} \) and (33) of \( k' \), and we can conclude (40).

Now, let us derive (40) for the whole time-span \([\tilde{k}, \bar{k}]\): in other words, let us prove (39), which states that, for all \( k \in [\tilde{k}, \bar{k}] \),

\[
\frac{\Delta_k(x + i)}{k} < 3 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i).
\]

By contradiction, assume that there exists \( \tilde{k} \in [\tilde{k}, \bar{k}] \) such that

\[
\frac{\Delta_k(x + i)}{k} \geq 3 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i),
\]

and define \( \bar{k} \) such that

\[
\bar{k} := \max \left\{ k \in [\tilde{k}, \bar{k}] : \frac{\Delta_k(x + i)}{k} < \frac{3}{2} \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) \right\}.
\]

Using that \( |\Delta_{k+1}(x + i) - \Delta_k(x + i)| \leq 1 + \alpha \), we have that

\[
\frac{\hat{k} - \tilde{k}}{\bar{k}} > \frac{1}{1 + \alpha} \left( 3 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - \frac{3}{2} \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) \right) > \frac{3 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - 1}{2(1 + \alpha) \times \frac{M}{d}} > \frac{6C_1 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i) - 1}{d}.
\]

Using Lemma 6.1, the walk is confined to \( \{x + i, \ldots, x + j + 1\} \) on the time-span \([\tilde{k}, \bar{k}]\). Using again Lemma 6.2, with \( i_1 = x + i, i_2 = x + j, k = \tilde{k} \) and \( k' = \bar{k} \), and using the hypothesis (38), we obtain

\[
\frac{\Delta_k(x + i)}{k} < \frac{\Delta_k(x + i)}{k} \times \frac{\tilde{k}}{k} < 3 \varepsilon M^{\frac{i(i-1)}{2}} + (j-i),
\]
which contradicts the assumption (42), proves (39) and finishes the first case $j - i \leq L - 1$.

(ii.b) Assume that $j - i \geq L$.

Here, we directly prove (39). By contradiction, assume that there exists $k \in [\hat{k}, \bar{k}]$ such that

$$\Delta_k(x + i) \geq 3\varepsilon M^{\frac{i(i-1)}{2} + (j-i)}, \quad (44)$$

which implies, by Lemma 6.1, that $X_k \in \{x + i, \ldots, x + j + 1\}$. Let us prove that the walker stays stuck forever in this interval. In other words, let us prove by induction that $X_k \in \{x + i, \ldots, x + j + 1\}$ for all $\hat{k} \geq \bar{k}$. This would contradict the definition of $R'$ and enable us to conclude.

Assume, for $\hat{k} \geq k$, that $X_m \in \{x + i, \ldots, x + j + 1\}$ for all $m \in [\hat{k}, \bar{k}]$, and let us prove that $X_{\hat{k}+1} \in \{x + i, \ldots, x + j + 1\}$.

On one hand, using that $d > \frac{\varepsilon}{\alpha}M^{K(K+1)}$ by (31), using (44), and applying Lemma 6.2, with $i_1 = x + i$, $i_2 = x + j$, $k = \hat{k}$ and $k' = \bar{k}$, with the hypothesis (38), we obtain

$$\Delta_k(x + i) \geq 3\varepsilon M^{\frac{i(i-1)}{2} + (j-i) - 6C_1\varepsilon M^{\frac{i(i-1)}{2} + (j-i)-1} > \varepsilon. \quad \text{(45)}$$

Thus, using Lemma 6.1, if $X_k = x + i$ then $X_{k+1} = x + i + 1$.

On the other hand, if $\hat{k} \leq k^*$, then $\Delta_k(x + j + 1) / \hat{k} < -\varepsilon$ and, therefore, by Lemma 6.1, if $X_k = x + j + 1$, then $X_{k+1} = x + j$. Otherwise, if $\hat{k} > k^*$, applying Lemma 6.2, with $i_1 = x + i$, $i_2 = x + j$, $k = k^*$ and $k' = \bar{k}$, with the hypothesis (38), and using (33) and (31), we obtain

$$\Delta_k(x + j + 1) \leq -3\varepsilon M^{\frac{(j+1)(j)}{2} + 6C_1\varepsilon M^{\frac{(j+1)(j)}{2} + (j-i)-1} < -3\varepsilon M^{\frac{(j+1)(j)}{2}}. \quad \text{(46)}$$

Thus, again using Lemma 6.1, if $X_k = x + j + 1$ then $X_{k+1} = x + j$. Therefore, by induction, this implies that $X_k \in \{x + i, \ldots, x + j + 1\}$ for all $\hat{k} \geq \bar{k}$, which contradicts the definition of $R'$ and concludes the second case, $j - i \geq L$, and the proof of the lemma.

6.2. Proof of Lemma 2.4

Fix $L \geq 1$ and $\alpha \in (\alpha_{L+1}, \alpha_L)$. Let $x, K \in \mathbb{Z}$ such that $K \geq L$, and fix $a > 0$.

Remind that Lemma 2.4 states that, almost surely,

$$\{R' = \{x, x + 1, \ldots, x + K + 1\} \subset \left\{ \sum_{k=1}^{+\infty} e^{a \beta |k(x+L+2) - a l_k (x+L+1)|} < +\infty \right\}. \quad (47)$$
**Proof of Lemma 2.4.** Let us work on the event \( \{ R' = \{ x, x + 1, ..., x + K + 1 \} \} \), where \( K \geq L \).

First, note that there exists a.s. \( N_1 \in \mathbb{N} \) such that, for all \( k \geq N_1 \), \( X_k \in R' \). Then, we use Proposition 2.2, which implies that for all \( \varepsilon > 0 \), there a.s. exists \( N_2 \in \mathbb{N} \) such that for all \( j \in \{ x + 1, ..., x + K \} \) and for all \( k \geq N_2 \),

\[
\left| \frac{\Delta_k(j)}{k} \right| < \frac{\varepsilon}{4}.
\]

Define \( N := \max (N_1, N_2) \).

We need the results on the linear system presented in Proposition 4.7. Notice that, if \( (\tilde{l}_0, ..., \tilde{l}_{K+2}) \) is such that \( \tilde{l}_0 = 0 \), \( \sum_{j=1}^{K+2} \tilde{l}_j = 1 \), and \( |\tilde{d}_j| < \varepsilon \) for all \( j = 1, ..., K \), where \( \tilde{d}_j \) is defined as in (15), then this vector can be seen as a perturbed solution of the linear system \( (E_K) \). Thus, by Proposition 4.7, \( \tilde{l}_{L+2} - \alpha \tilde{l}_{L+1} < -c(K)/2 \) as soon as \( \varepsilon \) is small enough.

Then, for any \( k \geq 2N \), define for all \( j \in \{ 0, ..., K+2 \} \),

\[
\tilde{l}_j = \frac{l_k(x + j) - l_N(x + j)}{k - N}.
\]

Then we have \( \tilde{l}_0 = \tilde{l}_{K+2} = 0 \), \( \sum_{j=1}^{K+2} \tilde{l}_j = 1 \) and, for all \( j \in \{ 1, ..., K \} \),

\[
|\tilde{d}_j| \leq \frac{|\Delta_k(x + j)| + |\Delta_N(x + j)|}{k} \times \frac{k}{k - N} < \varepsilon.
\]

This implies, as soon as \( \varepsilon > 0 \) is small enough, that

\[
\frac{(l_k(L+2) - l_N(L+2)) - \alpha (l_k(L+1) - l_N(L+1))}{k - N} < -\frac{c(K)}{2},
\]

therefore, for any \( a > 0 \), we can conclude the proof with

\[
\sum_{k=2N}^{+\infty} e^{a\beta |l_k(L+2) - \alpha l_k(L+1)|} \leq e^{a\beta |l_N(L+2) - \alpha l_N(L+1)|} \times \sum_{k=2N}^{+\infty} e^{-a \frac{c(K)}{2}(k-N)} < +\infty.
\]

\[ \square \]

7. **Proof of Theorem 1.5**

The goal of this section is to prove that if \( \alpha > 1 = \alpha_2 \), then the walk localizes on 3 vertices almost surely.

**Proof.** Fix \( x \in \mathbb{Z} \). We want to prove that \( \mathbb{P}(R' = \{ x, x + 1, x + 2, x + 3 \}) = 0 \). We will then conclude by taking the union over \( x \) and using Theorem 1.4.

Let us first prove the following lemma.
Lemma 7.1. For any constant $C > 0$, on the event $\{R' = x, x+1, x+2, x+3\}$, there a.s. exist infinitely many $k$’s such that one of the following statements holds:

- $X_k = x + 1$, $\Delta_k(x + 1) \leq -C$ and $\Delta_k(x + 1) + \Delta_k(x + 2) \leq -C$;
- $X_k = x + 2$, $\Delta_k(x + 2) \geq C$ and $\Delta_k(x + 1) + \Delta_k(x + 2) \geq C$.

Let $K$ be the set of those $k$’s.

Proof. Let us work on the event $\{R' = \{x, x+1, x+2, x+3\}\}$. Using Lemma 2.2, and solving equation $(E_K)$ in the case $L = 2$, one can deduce that $Z_k(x + 1)/Z_k(x)$ converges to $\alpha + 2$ (see Proposition 4.1).

Using Conditional Borel-Cantelli Lemma (see [8], chapter 4, (4.11)), we have, a.s.,

$$\lim_{m \to \infty} \sum_{k=1}^m 1_{\{X_k = x + 1\}} \mathbb{P}(X_{k+1} = x | F_k) / Z_m(x) = 1.$$ 

This implies that, for any $\varepsilon > 0$, there exist infinitely many $k$’s such that $X_k = x + 1$ and $\mathbb{P}(X_{k+1} = x | F_k) > \frac{1}{\alpha + 2} - \varepsilon$, and there exist infinitely many $k$’s such that $X_k = x + 1$ and $\mathbb{P}(X_{k+1} = x | F_k) < \frac{1}{\alpha + 2} + \varepsilon$. Otherwise, this would contradict Conditional Borel-Cantelli Lemma.

Then, there exists a positive constant $c_{\max}$ (resp. $c_{\min}$), depending only on $\alpha$ and $\beta$, such that $X_k = x + 1$ and $\Delta_k(x + 1) < c_{\max}$ (resp. $\Delta_k(x + 1) > -c_{\min}$) for infinitely many $k$’s.

If $k$ is large enough, then the walk does not leave the set $\{x, ..., x+3\}$. Therefore $\Delta_k(x + 1)$ decreases at most by $2\beta$ between two times where the walker is in $x + 1$. Hence, there exist infinitely many $k$’s such that $X_k = x + 1$ and

$$-c_{\min} \leq \Delta_k(x + 1) \leq c_{\max}.$$ 

Notice that we could give some explicit bounds $c_{\min}$ and $c_{\max}$ but it is not useful.

Now, notice that, on the event $\{R' = \{x, x+1, x+2, x+3\}\}$, $\lim_k \Delta_k(x) = +\infty$. Therefore, on this event, there exist infinitely many $k$’s such that: $-c_{\min} \leq \Delta_k(x + 1) \leq c_{\max}$, $X_k = x + 1$ and $\Delta_k(x) \geq C$, for any constant $C > 0$.

Then, assume that

$$k_0 \in \{k \in \mathbb{N} : -c_{\min} \leq \Delta_k(x + 1) \leq c_{\max}, X_k = x + 1, \Delta_k(x) \geq C\},$$

and let us prove that:

$$\mathbb{P}(\exists k \in [k_0, M + k_0] : k \in K | F_{k_0}) \geq \delta > 0,$$  \hspace{1cm} (45)

where $M := M(C, \alpha)$ and $\delta := \delta(C, \alpha)$ are two positive constants. Then, by Conditional Borel-Cantelli Lemma, this will imply the conclusion.

To finish this proof, let us consider two cases: $\Delta_{k_0}(x + 1) + \Delta_{k_0}(x + 2) < C$ and $\Delta_{k_0}(x + 1) + \Delta_{k_0}(x + 2) \geq C$. Let us show, in each case, that $(45)$ holds. This will imply the conclusion, by applying again Conditional Borel-Cantelli Lemma.
(i) Assume that $\Delta_{k_0}(x+1)+\Delta_{k_0}(x+2) < C$. As $-c_{\min} \leq \Delta_{k_0}(x+1) \leq c_{\max}$, this implies that $\Delta_{k_0}(x+2) < c_{\min} + C$. Then we have some control on the conditional probabilities to go from $x$ to $x+1$, from $x+1$ to $x$ and $x+2$, and to go from $x+2$ to $x+1$. Moreover, notice that, for all $k$,

$$\Delta_k(x+1) + \Delta_k(x+2) = -(\alpha - 1)(l_k(x+1) - l_k(x+3)) - \alpha l_k(x) + \alpha l_k(x+1).$$

(46)

Thus, with lower bounded probability, there exists

$$k_1 \in \left[ k_0, k_0 + c_{\max} + 4 \left( 1 + \frac{C}{\alpha - 1} \right) \right],$$

such that $X_{k_1} = x+1$ and:

$$l_{k_1}(x+1) - l_{k_0}(x+1) \geq 2C/(\alpha - 1),$$

$$l_{k_1}(x+2) - l_{k_0}(x+2) \geq l_{k_1}(x+1) - l_{k_0}(x+1) + c_{\max},$$

$$l_{k_1}(x) - l_{k_0}(x) = l_{k_1}(x+3) - l_{k_0}(x+3) = l_{k_1}(x+4) - l_{k_0}(x+4) = 0,$$

which implies that $\Delta_{k_1}(x+1) \leq -C$ and $\Delta_{k_1}(x+1) + \Delta_{k_1}(x+2) \leq -C$.

(ii) Assume that $\Delta_{k_0}(x+1)+\Delta_{k_0}(x+2) \geq C$ and recall that $-c_{\min} \leq \Delta_{k_0}(x+1) \leq c_{\max}$. Let us prove that, with lower bounded probability, there exists $k_1 \geq k_0$ such that $X_{k_1} = x+2, \Delta_{k_1}(x+2) > C$ and $\Delta_{k_1}(x+1) + \Delta_{k_1}(x+2) \geq C$.

First notice, by (46), that the visits to the edge $\{x+1, x+2\}$ do not change the value of $\Delta_{k_0}(x+1) + \Delta_{k_0}(x+2)$.

If $\Delta_{k_0}(x+2) > C$, then with lower bounded probability $k_1 = k_0 + 1$ because the walker just needs to jump from $x+1$ to $x+2$. Otherwise, $C - c_{\max} \leq \Delta_{k_0}(x+2) \leq C$ and we have some control on the conditional probabilities to jump from $x+1$ to $x+2$ and from $x+2$ to $x+1$, and we can lower-bound the probability to cross only the edge $\{x+1, x+2\}$, at least $c_{\max}$ times. Thus, with lower bounded probability, there exists $k_1 \in [k_0, k_0 + c_{\max} + 4]$ such that $X_{k_1} = x+2, \Delta_{k_1}(x+2) > C$ and $\Delta_{k_1}(x+1) + \Delta_{k_1}(x+2) \geq C$.

\[\square\]

Let us define by induction a non-decreasing sequence of stopping times. First, define the time $\tau_0 := \inf \{ k \geq 0 : k \in K \}$, then define, for all $n \geq 0$:

$$\tau_{2n+1} := \inf \{ k \geq \tau_{2n} : X_k = (x+3) \indic_{\{X_{\tau_{2n}}=x+1\}} + x \indic_{\{X_{\tau_{2n}}=x+2\}} \};$$

$$\tau_{2(n+1)} := \inf \{ k \geq \tau_{2n+1} : X_k \in K \}.$$

Notice that:

$$\{ R' = \{ x, x+1, x+2, x+3 \} \} \subset \bigcap_n \{ \tau_n < +\infty \}.$$
Let us prove that:

\[ P(\tau_{2n+1} < \infty | F_{\tau_{2n}}) 1_{(\tau_{2n} < +\infty)} < 1 - \delta, \]

for some \( \delta > 0 \), which depends only on \( \alpha, \beta \) and \( C \). This will enable us to conclude.

First, assume that some vector \((l_0, l_1, l_2, l_3)\) is such that \( l_0 \geq 0, l_3 = 0, -\alpha l_0 + l_1 - l_2 = d_1 \in \mathbb{R}, \) and \( l_1 + l_2 = 1 \). Define \( d_2 := -\alpha l_1 + l_2 \), then one can easily compute \( d_2 \) as a function of \( d_1 \) and \( l_0 \), and prove that:

\[
d_1 + d_2 = -\frac{\alpha - 1}{2} - \frac{\alpha - 1}{2} d_1 - \alpha \frac{1 + \alpha}{2} l_0. \tag{47}
\]

Note that this is a particular case of Corollary 4.6.

Now, assume that \( \{\tau_{2n} < +\infty\} \), and recall that \( \tau_{2n} \in K \). We will finish the proof assuming that \( X_{\tau_{2n}} = x + 1, \Delta_{\tau_{2n}}(x + 1) \leq -C \) and \( \Delta_{\tau_{2n}}(x + 1) + \Delta_{\tau_{2n}}(x + 2) \leq -C \). The other case, if \( X_{\tau_{2n}} = x + 2 \), is the exact symmetric of this one.

For any \( k \geq \tau_{2n} \), as long as \( l_k(x + 3) - l_{\tau_{2n}}(x + 3) = 0 \), using (47), we have

\[
\Delta_k(x + 1) + \Delta_k(x + 2) = \Delta_k(x + 1) + \Delta_k(x + 2) \\
- \Delta_{\tau_{2n}}(x + 1) - \Delta_{\tau_{2n}}(x + 2) \\
+ \Delta_{\tau_{2n}}(x + 1) + \Delta_{\tau_{2n}}(x + 2) \\
\leq -\frac{\alpha - 1}{2} (l_k(x + 1) + l_k(x + 2)) \\
- \frac{\alpha - 1}{2} (l_{\tau_{2n}}(x + 1) - l_{\tau_{2n}}(x + 2)) \\
- \frac{\alpha - 1}{2} (\Delta_k(x + 1) - \Delta_{\tau_{2n}}(x + 1)) - C.
\]

Thus, if

\[
\Delta_k(x + 1) - \Delta_{\tau_{2n}}(x + 1) > -\frac{1}{2} (l_k(x + 1) + l_k(x + 2) - l_{\tau_{2n}}(x + 1) - l_{\tau_{2n}}(x + 2)),
\]

then

\[
\Delta_k(x + 1) + \Delta_k(x + 2) < -\frac{\alpha - 1}{4} (l_k(x + 1) + l_k(x + 2) - l_{\tau_{2n}}(x + 1) - l_{\tau_{2n}}(x + 2)) - C,
\]

otherwise, as \( \Delta_{\tau_{2n}}(x + 1) \leq -C \),

\[
\Delta_k(x + 1) \leq -\frac{1}{2} (l_k(x + 1) + l_k(x + 2) - l_{\tau_{2n}}(x + 1) - l_{\tau_{2n}}(x + 2)) - C.
\]
To conclude, we just have to notice that

\[ P(\tau_{2n+1} < \infty | F_{\tau_{2n}}) \mathbb{1}_{\{\tau_{2n} < +\infty\}} \leq \sum_{k=\tau_{2n}}^{\infty} \mathbb{E} \left( \frac{\mathbb{1}_{\{X_k=1,l_k(3)=l_{\tau_{2n}}(3)\}}}{1 + e^{-2\beta \Delta_k(1)}} \ 1 + e^{-2\beta \Delta_k(2)}} \right) \]

\[ \leq \sum_{k=\tau_{2n}}^{\infty} \mathbb{E} \left( \mathbb{1}_{\{X_k=1,l_k(3)=l_{\tau_{2n}}(3)\}} e^{2\beta \Delta_k(1)} \land e^{2\beta [\Delta_k(1) + \Delta_k(2)]} \right) \]

\[ \leq \sum_{k=0}^{\infty} e^{-2\beta \left( \frac{\alpha_0}{4} \land \frac{1}{2} \right) k + C} \]

\[ \leq \frac{e^{2\beta \left( \frac{\alpha_0}{4} \land \frac{1}{2} \right)}}{2\beta \left( \frac{\alpha_0}{4} \land \frac{1}{2} \right)} e^{-C} \]

\[ \leq 1 - \delta, \]

choosing \( C = C(\alpha, \beta) \) large enough and for some \( \delta = \delta(\alpha, \beta) > 0 \). This concludes the proof.

\[ \square \]

8. Generalizations

In [10], interesting generalizations are proposed. One of them is the case where the interaction depends on more than the four neighbouring edges, i.e. replacing the definition of \( \Delta_n(j) \) by:

\[ \alpha_0 l_n(j-k) + ... + \alpha_1 l_n(j-1) + \alpha_0 l_n(j) - \alpha_0 l_n(j+1) - ... - \alpha_k l_n(j+1+k), \]

for some \( \alpha_0,...,\alpha_k \). The techniques of [10], as it is noticed therein, seem to be adaptable to derive results about such models, by investigating the behavior of the associated generalized Fibonacci sequence. Moreover, in some cases, we believe that our techniques are also adaptable. In particular, we could adapt the variant of the Rubin’s construction as it is done in the present paper and apply it to these models, as soon as \( \alpha_1,...,\alpha_k \) are nonpositive. The parameter \( \alpha_0 \) could be positive. In these cases, we could recover some sort of weight function, which could be decreasing with respect to the local times on neighbouring edges but non-decreasing with respect to local times on further edges.

Finally, we refer the reader to the concluding remarks of [10], that have been very useful to the author, to learn more about some open problems directly related to the model studied in the current paper.

Acknowledgements. I would like to thank my PhD advisor Pierre Tarrès for introducing me to this problem, for motivating discussions and for uncountably many comments on earlier versions of this work.
