In this paper, we analyse a curvature- and torsion-square quantum gravity action with an additional Holst term minimally coupled to a massive Dirac field in four dimensions. The main purpose here is to try to estimate and compare the value of the Barbero-Immirzi (BI) parameter with its currently known results. To do that, we work out the physical mass of the fermion as a function of this parameter in a perturbative one-loop calculation, assuming the scenario of a physics at the TeV-scale.

I. INTRODUCTION

It is well-known that the Einstein-Cartan theory represents the simplest extension of General Relativity (GR) in the presence of the torsion field. However, it is a non-renormalizable quantum theory, in spite of describing physics with a very good approximation at the classical level. In view of that, several investigations followed in order to set up approaches to the gravitational interaction that may prove relevant to our understanding of the quantum gravity problem. A fruitful approach has been the theory of higher-order curvature invariants, whose actions contain terms quadratic in the curvature, considering also all possible quadratic terms that can be constructed with torsion, in addition to the Einstein-Hilbert term. Furthermore, these terms are necessary if we wish to obtain an effective action for quantum gravity at scales close to the Planck length. This proposal is not yet free from problems. The main interest in such theories comes, in particular, from Cosmology. In this case, the possibility that the graviton has a small mass to explain the early stages of the Universe depends on the particular quantum theory of gravity. Moreover, torsion could, in principle, be associated to any astrophysical scale.

In a more contemporary context of non-perturbative approaches to quantum gravity, Loop Quantum Gravity arose as another possible quantization method. The heartwood of this scheme is the idea that the fundamental variable for quantization is the connection, rather than the metric. It was proposed by Asthtekar by working only with the self-dual part of the SU(2)-connection, referred to as Asthtekar-Barbero parameter. This is actually a canonical theory of gravity in terms of a real connection. In a Lagrangian approach, the parameter is taken as a new dimensionless parameter introduced with the meaning of a coupling constant of a topological odd-parity term added to the Hilbert-Palatini action, which is treated in the first-order formalism and yields the so-called Holst action. This topological term, in GR, does not affect the equations of motion in the absence of torsion since it appears as a factor in a term that vanishes on the mass-shell. Although is non-physical at classical level, we find that it becomes an essential parameter at the quantum level, appearing in several contexts, such as, the spectrum of area and volume operators, in the black hole entropy formula and in the dynamics provided by the more modern spin foam models. It should be noticed that there is another method to quantize gravity known as the quantum Regge calculus, which is -independent.

For these reasons, over the latest years, several attempts to fix the parameter have been worked out. Dreyer, motivated by Hod’s work on the asymptotic quasi-normal modes of black holes, proposed a novel way to fix this parameter. In order that the Bekenstein-Hawking entropy formula and quasi-normal mode agree, the BI parameter should be given by \( \beta = \ln \frac{3}{\sqrt{2\pi}} \).

In a recent paper, considering Faddeev’s formulation of gravity, Khatsymovsky found out that the elemen-
tary area spectrum is proportional to the BI parameter with the value $\beta = 0, 39$. Requiring the validity of the Bekenstein-Hawking area law relating the two parameters that characterize the quantum states of black hole horizon, A. Majhi et al obtained the following range for $\beta$: $0.159 < \beta < 0.225$ [23, 24]. In the latest paper that, to our knowledge, addresses this issue, the authors have obtained the value $\beta = \ln 3/\pi$, through the calculation of the entropy for an arbitrary non-rotating isolated horizon [15].

It is worthy mentioning that all references previously quoted estimate the $\beta$ parameter making use of a non-perturbative approach to QG. In this paper, we follow an alternative route, by studying perturbative QG [25] in the first-order (tetrad) formalism, to understand which is the role of the $\beta$ parameter in the loop corrections to a model discussed in Ref. [26], enriched by implementing the Holst term, with minimal coupling between fermions and torsion. This choice is motivated by the fact that, in the Einstein-Cartan theory, the torsion field becomes relevant only in the presence of fermionic currents and, more recently, coupling fermions to classical GR has attracted a great deal of attention, since that A. Perez and C. Rovelli [27] have demonstrated that the minimal coupling to fermions renders gravity sensitive to the $\beta$ parameter [28]. We tackle the issue of a 1-loop mass generation mechanism for the fermion as well as the possible influence of the BI parameter on this mechanism.

The outline of this work is the following. In Section II we briefly review the main results of the Holst action at the Lagrangian level and we present a description of the model discussed in Ref. [20], as well as our conventions together with the propagators of the model. Also, since the Dirac field couples to the affine connection and the intrinsic spin of fermions acts as a source for torsion, in Section III we study an extension of the our model in order to include the minimal coupling between torsion and the Dirac spinor. Finally, in Section IV we cast our Discussions and Conclusions.

II. DESCRIPTION OF THE MODEL

We adopt to work with the first-order formalism, in which configuration space consists of two independent field variables, namely, the space-time $SO(4)$ gauge spin connection, $\omega_{\mu}^{\ ab}$, and the vielbein, $e_{\mu\ a}$. This choice is justified for we think that it is a more fundamental approach to gravitation, since it is based on the fundamental ideas of the Yang-Mills approach. The gravitational Lagrangian (Einstein-Cartan term) together with the Holst invariant, where the latter is multiplied by a parameter in the loop corrections

\[ \mathcal{L}_{EC} + \mathcal{L}_H = e \left( -\alpha R + \frac{\alpha}{2\beta} e_{\mu\ b}^{\ a} e^{ab}_{\ cd} R_{\mu\nu}^{\ cd} \right), \tag{1} \]

where $\alpha = \frac{1}{16\pi G}$, $e$ denotes the absolute value of the determinant of the co-tetrad, $R_{\mu\nu}^{\ cd}$ is the field strength associated with the spin connection $\omega_{\mu}^{\ ab}$ which is not torsion-free, and $\epsilon_{abcd}$ denotes the 4-dimensional Levi-Civita tensor. In pure gravity, $\beta$ does not affect the graviton equation of motion. This is no longer the case when fermions are present. In this respect, the effective Dirac action contains an axial current-current interaction whose dependence on $\beta$ becomes non-trivial; also, this parameter cannot take an arbitrary value, so that we have to fix it by calculating some observable effect.

Our motivation in this paper is to investigate the possible relevance of the BI parameter at the quantum level, considering the most general parity-preserving Lagrangian that describe massive gravitons studied in the Ref. [26] with an additional Holst term, as given below:

\[ \mathcal{L} = e \left( -\alpha R + \chi R^2 + \rho R_{\mu a} R^{\mu a} + \gamma R_{\mu a b} R^{\mu a b} + \xi R_{\mu a b} R_{\nu}^{\mu a b} + k R_{\mu a b} R_{\nu}^{\mu a b} + \lambda R_{\mu a b} R^{\mu a b} \right) + \alpha \beta \left( \frac{2}{\alpha} \epsilon_{\mu a}^{\ b} \epsilon_{\nu b}^{\ ab} \right), \tag{2} \]

where $\chi, \beta, \gamma, \xi, k, \lambda$ and $\beta$ are arbitrary dimensionless constants and the others parameters have canonical dimensions given by $[s] = [t] = [r] = 1$.

The particular choice of the Lagrangian above, Eq. (2), is justified by the fact that, by suitably choosing special regions in parameter space, it yields a healthy spectrum of excitations, with massive gravitons and no ghosts or tachyons present, despite the presence of higher powers of curvature and torsion terms. This has been discussed in the works of Refs. [26, 29]. Other terms with powers of torsion could be considered; they would however spoil the consistency of the action, in that ghosts or tachyons would be present and would not decouple from the physical sector [26, 29]. This is why we restrict ourselves to the terms present in the action [2].

Our conventions are:

\[ R_{\mu\nu}^{\ ab} = \partial_{\mu} \omega_{\nu}^{\ ab} - \partial_{\nu} \omega_{\mu}^{\ ab} + \omega_{\mu}^{\ a c} \omega_{\nu}^{\ cb}, \tag{3} \]

\[ R_{\mu}^{\ a} = e_{b}^{\ a} R_{\mu}^{\ ab}, \tag{4} \]

\[ R = e_{a}^{\ b} e_{b}^{\ a} R_{\mu\nu}^{\ ab}, \tag{5} \]

and

\[ \eta_{\mu\nu} = (1, -1, -1, -1), \tag{6} \]

where the Greek indices refer to the world manifold and the Latin ones stand for the frame indices.

The torsion tensor has 24 independent components in four space-time dimensions and, by considering the irreducible representations of $SO(1,3)$, it may be split into a vector, $e^{\mu}$, an axial vector $a^{\mu}$, and a rank-three tensor.
where \( g_{\mu \nu} = \eta_{ab} e_\mu^a e_\nu^b \) is the metric tensor. The splitting of Eq. (7) for \( T_{\nu \mu \alpha} \) in \( SO(1,3) \)-irreducible components is simply a group-theoretic decomposition. So long as a dynamical model is concerned, it is perfectly legitimate to truncate some of the components in RHS of Eq. (7) if we choose to restrict our considerations to this dynamical model. This is the reason why we allowed to suppress them and we build up our model in such a way that only the \( a^\mu \)-vector acquires dynamical and can be excited by the interaction with the fundamental fermions of the Standard Model. This is the reason why we allowed to suppress them and we build up our model in such a way that only the \( a^\mu \)-vector acquires dynamical and can be excited by the interaction with the fundamental fermions of the Standard Model.

Next, we perform the split of the vielbein,

\[ e^\mu_a = \delta^\mu_a + h^\mu_a, \]

namely, the Minkowski background and a perturbation, \( h^\mu_a \), around the background. In addition, the fluctuation can be decomposed as

\[ h_{ab} = \frac{1}{4} \eta_{ab} s + \epsilon_{abcd} \partial^c W^d. \]

Before we proceed, we recall that the spin connection \( \omega^\mu_{\ ab} \) may be expressed as

\[ \omega^\mu_{\ ab} = \bar{\omega}^\mu_{\ ab} + K^\mu_{\ ab}, \]

where \( \bar{\omega}^\mu_{\ ab} \) is the Riemannian part of the spin connection

\[ \bar{\omega}^\mu_{\ ab} = \frac{1}{2} \epsilon_{\mu \rho} \left( \Omega^{ab}_\rho + \Omega^{ac}_\rho - \Omega^{bc}_\rho \right), \]

where \( \Omega_{cba} = \epsilon^{\mu \rho} \partial_{\mu} e_{\rho \nu} - \partial_{\nu} e_{\rho \mu} \) stands for the rotation coefficients. \( K^\mu_{\ ab} \) are the components of the contorsion tensor, defined by

\[ K^\mu_{\ ab} = \frac{1}{2} \left( T^\mu_{\ ab} - T^\mu_{\ ab} \right). \]

It is worthy noticing that, while the contortion tensor is antisymmetric in the last two indices, the torsion tensor is antisymmetric in the first two indices.

Using equations (7) to (12), the spin connection fluctuation may be put into a more useful form, namely:

\[ \omega_{\ mu}^{\ ab} = \frac{1}{8} \left( \delta_{\ mu}^{\ \beta} \partial^{\alpha} s - \delta_{\ mu}^{\ \alpha} \partial^{\beta} s \right) + \frac{1}{2} \left( \epsilon^{\beta \mu \alpha \gamma \delta \sigma} - \epsilon^{\alpha \mu \beta \gamma \delta \sigma} \right) \partial^{\beta} W^\lambda \]

\[ + \frac{1}{3} \left( \delta_{\ mu}^{\ \beta} \partial^{\gamma} \eta_{\ ab} - \partial_{\ mu}^{\ \gamma} \eta_{\ ab} \right) + \frac{1}{2} \epsilon_{\mu \alpha \beta \gamma \delta \sigma} \lambda s^\lambda. \]

At this point, it is worthy to stress that in the presence of torsion, the Gauss-Bonnet term does not correspond any longer to a topological invariant, for it cannot be expressed as a total divergence [30]. Thus, all the quadratic terms in the curvature present in the Lagrangian [2] must be kept in our considerations.

Finally, we can obtain the relevant part of the bilinear expansion of the Lagrangian [2]. Making use of equation [13], after a lengthy but straightforward calculation, we obtain

\[ L = s \left[ \frac{3}{16} \left( \rho + \gamma + \xi + 3 \chi + k + \frac{\lambda}{2} \right) \partial - \frac{39 \alpha}{32} \right] \square s \]

\[ + v^\mu \left( \frac{7}{2} \rho + \gamma - \xi - 3 \chi + k + \frac{5 \lambda}{12} \right) \partial_\mu s \]

\[ + v^\mu \left[ \left( \frac{\rho}{4} + \frac{2 \lambda}{9} + \frac{8 \xi}{9} \right) \eta_{\mu \nu} \square - \frac{4}{3} \left( \frac{2 \rho}{3} - \gamma + \xi + 3 \chi + k + \frac{5 \lambda}{3} \right) \partial_\mu \partial_\nu \right. \]

\[ + \left. \frac{2 \alpha}{3} \partial_\mu \partial_\nu + \left( \frac{\rho}{2} - \gamma - 2 \xi - 2 k - \lambda \right) \partial_\mu \partial_\nu \right] \square w^\mu \]

\[ + \left( \frac{3}{2} \rho - \gamma + 4 \chi - 4 k - \frac{3 \lambda}{2} \right) \square w^\mu \]

\[ + a^\mu \left[ \left( \frac{\rho}{2} - \gamma - 2 \xi - 2 k \right) \square + 2 \alpha \eta_{\mu \nu} \right] w^\nu \]

\[ + a^\mu \left[ \left( \frac{\rho}{2} - \gamma - 2 \xi - 2 k \right) \square - \frac{3}{2} \left( \frac{\alpha}{2} + 2 \gamma + 2 y \right) \eta_{\mu \nu} \right] a^\nu \]

\[ - a^\mu \left( \frac{2 \alpha}{8} \right) \partial_\mu s - a^\mu \left( \frac{2 \alpha}{8} \right) \eta_{\mu \nu} v^\nu. \]

Two important observations are in order. The \( w^\mu \)-field is not sensitive to the BI parameter, so that we decide to truncate it from the decomposition of the metric. The second observation concerns the fact that, in the next Section, we shall consider the minimal fermion coupling in the presence of massive Dirac fields. As well-known, a Dirac particle only interacts with the totally antisymmetric part of the torsion, so that we can disregard the vector component of the torsion. Therefore, the Lagrangian [13] can be written only in terms of the scalar component of the metric and the pseudo-vector component of the torsion. We understand that only the \( s \)- and \( a^\mu \)-fields should contribute effects whenever fermions are introduced. This is why we truncate the \( v^\mu \)- and \( w^\mu \)-fields.
from the Lagrangian \[14\]. Thus,

\[
\mathcal{L} = \frac{3}{16} \left( \rho + \gamma + \xi + k + 3\chi + \frac{\lambda}{2} \right) s\Box^2 s - \frac{39\alpha}{32} s\Box s \\
+ \left( -\frac{\rho}{2} + \frac{\gamma}{2} - 2\xi + 2k \right) (\partial_{\mu} a^\nu)^2 \\
+ \left( \frac{\rho}{2} - \frac{\gamma}{2} - \xi - 2k + \frac{3\lambda}{2} \right) (\partial_{\mu} a^\mu)^2 \\
-3 \left( \frac{\alpha}{2} + 2x + 2y \right) a^\mu a_\mu - \frac{21\alpha}{4\beta} a^\mu \partial_{\mu} s.
\]  
\tag{15}

The coefficients in the expression \[15\], except the constant \(\alpha\) are arbitrary parameters. By setting

\[
-\frac{\rho}{2} + \frac{\gamma}{2} - 2\xi + 2k = 0, 
\tag{16}
\]

and

\[
\frac{\rho}{2} - \frac{\gamma}{2} - \xi - 2k + \frac{3\lambda}{2} = 0, 
\tag{17}
\]

we get \(\xi = \lambda/2\). So, the Lagrangian \[16\] can be written in terms of the new parameters as

\[
\mathcal{L} = As\Box^2 s + Fs\Box s + Ba^\mu a_\mu + Ha^\mu \partial_{\mu} s, 
\tag{19}
\]

where

\[
A = \frac{3}{16} \left( \rho + \gamma + \xi + k + 3\chi + \frac{\lambda}{2} \right), \quad B = -\frac{3\alpha}{2}, 
\tag{20}
\]

\[
F = -\frac{39\alpha}{32}, \quad H = -\frac{21\alpha}{4\beta}. 
\tag{21}
\]

If we make use of equation \[19\], we can immediately obtain the equation of motion for the axial vector field, \(a^\mu\), which reads

\[
a_{\mu} = -\frac{7}{4\beta} \partial_{\mu} s. 
\tag{22}
\]

With the free parameters of our model chosen according to the relations of Eqs. \[16\] - \[18\], we are led to the Lagrangian of Eq. \[19\], where it is clear that the vector \(a^\mu\) becomes an auxiliary field: it appears algebraically, so it has no independent dynamics. Therefore, it can be solved by its algebraic equation of motion in terms of the \(s\) - field, as it will be done below.

For the sake of a better comprehension, we should perhaps justify why the relations of Eqs. \[16\] - \[18\] are imposed. The reason behind the choices of Eqs. \[16\] and \[17\] is to suppress the unphysical (ghost-type) excitation that would show up from \((\partial_\mu a^\nu)\) and from the symmetric part \((\partial_\mu a^\mu)\): the spin - 0 ghost carried by \((\partial_\mu a^\nu)\) and \((\partial_\mu a^\mu + \partial_\mu a^\mu)\) would spoil the tree-level unitarity of our model. Finally, condition \[18\] is assumed in order to exclude from our model a Planckian mass that would otherwise be present in the spectrum of excitations of \(a^\mu\), as the calculation of its propagator reveals.

Hence, the Lagrangian \[19\] finally takes the form

\[
\mathcal{L} = As\Box^2 s + \left( F + \frac{H^2}{4B} \right) s\Box s. 
\tag{23}
\]

Before going on, one remark is in order. The next step is to read off the Feynman propagator for the scalar field \(s\). After a direct computation from \[23\], we attain

\[
D_F(p) = \frac{i}{2(F + \frac{H^2}{4B})} \left\{ \frac{1}{p^2} + \frac{1}{p^2 - m^2} \right\}, 
\tag{24}
\]

where

\[
m^2 = \frac{1}{A} \left( F + \frac{H^2}{4B} \right). 
\tag{25}
\]

Since that we are working in scenarios with low scales, up to a few Tev, and the mass \(m\) is at the Planck scale, the Appelquist-Carazzone theorem ensures that the effects of the Planckian loops are not detectable in the Tev scale. So, in view of the suppression of the effects of the Planckian massive excitation \((p^2 = m^2)\) by powers of \(1/m^2\), for the sake of our considerations the propagator for the scalar field may be taken as follows:

\[
D_F(p) = -\frac{i}{2(F + \frac{H^2}{4B})} \frac{1}{p^2}. 
\tag{26}
\]

Once we have analyzed the spectrum of excitations that arise from the gravity sector, we shall be now concerned with the introduction of fermions and our main goal shall be the computation of the effects of the (virtual) gravity models on the fermion self-energy and, in doing so, we shall track the effects the BI parameter contributes to the fermion masses.

### III. COUPLING WITH FERMIONIC MATTER FIELDS

Over the past years, there has been a great deal of interest in the study of Dirac fields in curved spacetime. Particularly, it was shown by Perez and Rovelli [26] and by Freidel, Minic and Takeuchi [1] that, whenever minimally coupled, spinor fields present in the Einstein-Cartan theory with the Holst term prevent the latter of being a truly topological action. In presence of fermions, we have a modification in the structure of the spacetime, leading to a non-vanishing torsion field. Therefore, we have a classical-level interpretation of this parameter, which is related with axial-axial current interactions. Now, in order to better understand the effect of the BI parameter in Particle Physics, let us calculate the corrections to the fermion mass due to this parameter in the model describe in the previous Section.
The Lagrangian density which corresponds to the Dirac equation in curved space-time is

\[
L_D = \epsilon \left( \frac{i}{2} \epsilon^\mu a \bar{\psi} \gamma^a D_\mu \psi - \frac{i}{2} \epsilon^\mu a D_\mu \bar{\psi} \gamma^a \psi - m_0 \bar{\psi} \psi \right).
\] (27)

The covariant derivative acting on a spinor is

\[
D_\mu \psi = \partial_\mu \psi + \frac{g}{8} \omega_\mu^{\alpha \beta} \left[ \gamma_\alpha, \gamma_\beta \right] \psi,
\] (28)

where \( \gamma_\mu = \epsilon_\mu \gamma^a \), \( a, \mu = 0, 1, 2, 4 \), \( \gamma_\alpha \) are the usual flat space-time Dirac matrices, \( g \) is a dimensionless coupling constant and \( m_0 \) is the mass of the Dirac field. According to the discussion in the Section [1] we are working only with the scalar field, \( s \), and the pseudo-vector, \( a^\mu \), so that the spin connection can be written as

\[
\omega_\mu^{\alpha \beta} = \frac{1}{8} \left( \delta_\mu^{\beta} \partial^\alpha s - \delta_\mu^{\alpha} \partial^\beta s \right) + \frac{1}{2} \epsilon_\mu^{\alpha \beta \lambda} \Lambda^\lambda.
\] (29)

Replacing (28) and (29) into (27), and making use of the identity

\[
\gamma^\alpha \gamma^\beta \gamma^\gamma = \gamma^\alpha \eta^{\beta \gamma} + \gamma^\gamma \eta^{\alpha \beta} - \gamma^\beta \eta^{\alpha \gamma} + i \epsilon^{\alpha \beta \gamma \delta} \gamma^\delta,
\] (30)

we arrive, after some algebra, to the relation

\[
L_D = \left( \frac{i}{2} \bar{\psi} \gamma^\mu \partial_\mu \psi - \bar{\psi} \gamma^\mu \partial_\mu \psi \right) - m_0 \bar{\psi} \psi
+ i \frac{s}{2} \left( \bar{\psi} \gamma^\mu \partial_\mu \psi - \bar{\psi} \gamma^\mu \partial_\mu \psi \right) + \frac{3g}{4} (1 + s) a^\mu \bar{\psi} \gamma_\mu \gamma_5 \psi
- m_0 s \bar{\psi} \psi.
\] (31)

Using equation (23), together the Dirac Lagrangian (28), we can obtain the new equation of motion for the auxiliary axial vector field, \( a^\mu \), which reads

\[
a^\mu = - \frac{7}{4g} \gamma^\mu s + \frac{9}{4s} (1 + s) \bar{\psi} \gamma_5 \gamma^\mu \psi.
\] (32)

Here, it is worthwhile to recall that, since \( a^\mu \) appears as an auxiliary field, it is perfectly licit procedure to replace it in the Dirac coupled action by its equation of motion (32). Previously, \( a^\mu \) was given by Eq. (22). With the coupling to the fermions, the axial vector condensate \( \bar{\psi} \gamma^\mu \gamma_5 \psi \) contributes and, as it follows below, upon replacement of \( a^\mu \) by Eq. (32) in the original Dirac action, one obtains the following interaction Lagrangian:

\[
\mathcal{L}_{int} = \frac{i s}{2} \left( \bar{\psi} \gamma^\mu \partial_\mu \psi - \bar{\psi} \gamma^\mu \partial_\mu \psi \right) - \frac{21g}{16\beta} (1 + s) \partial_\mu \bar{\psi} \gamma_\mu \gamma_5 \psi
+ \frac{3g^2}{16\beta} (1 + s)^2 (\bar{\psi} \gamma_5 \gamma^\mu \psi)^2 - m_0 s \bar{\psi} \psi,
\] (33)

where now a 4-fermion contact appears as a consequence of the non-dynamical character of the \( a^\mu \)-axial field.

One can observe that the coupling constant of this interaction depends on the BI parameter. Let us consider the Feynman rules for the Lagrangian (23). The momenta in this paper are incoming to the vertices. Thus, the fermion-scalar 3-vertex takes the form

\[
\frac{i}{2} (p + p) \gamma^\mu - \frac{21g}{16\beta} q_\mu \gamma_5 \gamma^\mu - im_0,
\] (34)

and the other two vertices that describes the four-fermion interaction are given by

\[
\frac{21g}{16\beta} q_\mu \gamma_5 \gamma^\mu,
\] (35)

and

\[
\frac{3g^2}{16\alpha} \gamma_5 \gamma^\mu \gamma_5 \gamma_\mu.
\] (36)

The propagator for the spinor field is given by

\[
S_F (p) = \frac{i}{p - m_0}.
\] (37)

From these results, we turn into the calculation of the self-energy corrections to the fermion propagator and discuss the mechanism of mass generation for the fermion field, by looking at the pole(s) of its 1-loop corrected 2-point function. For the fermion self-energy graph, we find

\[
- i \Sigma (p) = \int \frac{d^4q}{(2\pi)^4} \left\{ \frac{i}{2} (2\hat{\beta} - \hat{\gamma}) - \frac{21g}{16\beta} \gamma_5 \hat{\gamma} - im_0 \right\}
\times \hat{\beta} - \hat{\gamma} + m_0
\times \frac{i}{2} (2\hat{\beta} - \hat{\gamma}) - \frac{21g}{16\beta} \gamma_5 \hat{\gamma} - im_0
\times \left\{ \frac{i}{2} (2\hat{\beta} - \hat{\gamma}) - \frac{21g}{16\beta} \gamma_5 \hat{\gamma} - im_0 \right\}
\times -Tr \int \frac{d^4k}{(2\pi)^4} \frac{3g^2}{16\alpha} \gamma_5 \gamma^\mu \gamma_5 \gamma_\mu \frac{k + m_0}{k^2 - m_0^2}.
\] (38)

The result for the divergent part of the 1-loop self-energy of the fermion has the following final form

\[
\Sigma (p) = \frac{1}{\pi^2 \alpha \varepsilon} \left\{ \left\{ \frac{2\beta^2}{3(13\beta^2 + 49)} \left[ p^2 - m_0^2 + \frac{2g^2}{441g^2} \right] \right\}^{1/4} + \frac{3g^2}{8} \right\}
\times \left[ \left( \frac{2g^2}{441g^2} \right) p^2 + \left( 1 - \frac{441g^2}{441g^2} \right) m_0 \gamma_5 \gamma_5 \gamma_5 \gamma_5 \right]
\times + \frac{7ig\beta}{48(13\beta^2 + 49)} \left( 19p^2 + 3m_0^2 \right) p_\mu \gamma^\mu \gamma_5 \gamma_5,
\] (39)

where \( \varepsilon^{-1} = \ln (A^2/\mu^2) \) is the parameter of dimensional regularization, \( A \) is the cut-off and \( \mu \) is an arbitrary mass parameter.

The insertion of this 1-loop graph leads to the following 1-loop corrected Lagrangian

\[
\mathcal{L} = \bar{\psi} \left( \gamma^\mu p_\mu - m_0 - \Sigma \right) \psi = \bar{\psi} O\psi.
\] (40)

We are now ready to find the 1-loop corrected fermionic propagator and then the relation between the bare and
the physical mass of the fermion in our model. The practical calculation for that follows the standard scheme and we do not report the details. The result is the on-shell relation
\[
(D^2 - E^2 + C^2 - 2E \cdot C) (D^2 - E^2 + C^2 + 2E \cdot C) + 4E^2 C^2 = 0,
\]
where we have used the simplified notation, \( E^2 = E_\mu E^\mu \), and the fact that \( p^2 = m^2 \). We omit the full result of eq. (41), which is very lengthy. We report below only the parts of interest for our actual considerations:

\[
D = -m_0 \left\{ \frac{2\beta^2}{3\pi^2 \alpha \epsilon (13\beta^2 + 49)} \left[ 3m^2 - \frac{1}{4} \left( 1 + \frac{441g^2}{64\beta^2} \right) m_0^2 \right] + 1 \right\},
\]

\[
E_\mu = \left\{ 1 + \frac{\beta^2}{12\pi^2 \alpha \epsilon (13\beta^2 + 49)} \left[ \frac{1}{3} \left( 79 - \frac{3087g^2}{64\beta^2} \right) m^2 + \left( 1 - \frac{441g^2}{64\beta^2} \right) m_0^2 \right] \right\} p_\mu,

\]

IV. DISCUSSIONS AND CONCLUSIONS

Our main interest in this paper has been the study of the effect of the BI parameter on the mass of a fermion in the context of a particular Extended Theory of Gravity with explicit torsion terms. For this purpose, we have performed one-loop calculations in this model with gravity and fermions minimally coupled. Proceeding this way, and adopting the physical mass of the fermion at the LHC scale, we expected to obtain an estimate for the BI parameter. Unfortunately, this could not be done, for the equation (41) depends on the free parameters, namely, the cut-off \( \Lambda \), the arbitrary mass parameter \( \mu \) and the bare mass of the fermion, \( m_0 \). For this reason, we proceed further to adopt an alternative route. As a first step, we fix the parameters \( \Lambda \), \( \mu \) and \( m_0 \), choosing an appropriate energy scale, such as the LHC energy range. With these considerations in mind, we obtain a relation between \( m \) and \( \beta \). As one should expect, the corrections to the fermion mass are extremely small. By inspection of the plot, we see that the fermion mass increase if the BI parameter lies in the range \( 0 < \beta < 1.185 \), reaching its maximum value at \( \beta = 1.185 \). In this interval of values, the potential term in Dirac interaction Lagrangian dominates the kinetic term. Furthermore, when \( \beta \to 0 \), the fermion mass is finite. In particular, in the range \( 0 < \beta < 0.195 \), the physical mass of the fermion is less than his bare mass. On the other hand, for values of \( \beta \) greater than 1.185, the kinetic term dominates the potential term. In conclusion, our result is compatible with the known results in the literature for

\[\Lambda = 250 \text{ MeV} \] (corresponding to QCD cut-off), \( \mu = 1 \text{ MeV}, g = 1, m_0 = 250 \text{ MeV} \) and \( 0 < \beta < 5.0 \). As one should expect, the corrections to the fermion mass are extremely small. By inspection of the plot, we see that the fermion mass increase if the BI parameter lies in the range \( 0 < \beta < 1.185 \), reaching its maximum value at \( \beta = 1.185 \). In this interval of values, the potential term in Dirac interaction Lagrangian dominates the kinetic term. Furthermore, when \( \beta \to 0 \), the fermion mass is finite. In particular, in the range \( 0 < \beta < 0.195 \), the physical mass of the fermion is less than his bare mass. On the other hand, for values of \( \beta \) greater than 1.185, the kinetic term dominates the potential term. In conclusion, our result is compatible with the known results in the literature for
the BI parameter.

The point of view we have tried to convey in this paper is that the present established limits for the BI parameter are compatible with the spectrum of fermions with masses at the LHC scale. Our study shows that the Standard-Model charged leptons and quarks would not be sensitive to the BI parameter, but we understand that the whole sector of TeV-scale massive fermions, such as the charginos and neutralinos, could be a good probe of the BI parameter in the realm of Particle Physics. We would like to point out that the model we present here is still too limited. To our mind, the next immediate step towards a more realistic model, namely, the inclusion of the BI parameter in the framework of Supersymmetry (more specifically, the minimal SUGRA model), would be the right landscape for the investigation we are reporting in this paper. We are now concentrating efforts in this direction and we expect to report soon our first efforts elsewhere.
