Abstract

All three-loop on-shell QCD Feynman integrals with two masses can be reduced to 27 master integrals. Here we calculate these master integrals, expanded in $\varepsilon$, both exactly in the mass ratio and as series in limiting cases.

1 Introduction

Massive on-shell Feynman integrals have numerous applications. We consider two-leg diagrams, where the external particle has mass $M$ and an on-shell momentum $p$ ($p^2 = M^2$), in QCD or QED\textsuperscript{1}. On-shell Feynman integrals with a single mass $M$ have been investigated at two \cite{123} and three \cite{1234} loops. Starting from two loops, diagrams with loops of massive particles having a different mass $m$ appear. Such diagrams are non-trivial functions of the ratio

$$x = \frac{m}{M}. \quad (1.1)$$

At two loops, there is one generic class of diagram\textsuperscript{2} in QCD and QED (Fig. 1). The corresponding Feynman integrals can be reduced to 4 master integrals

\textsuperscript{1} These results are also useful in the electroweak theory, or more general field theories; but there additional classes of diagrams appear.
\textsuperscript{2} We use the following definitions: a \textit{class} consists of diagrams with identical denominators, or whose denominators can be made identical by linear substitutions.
(Fig. 2), coefficients being rational functions of $d = 4 - 2\varepsilon$ and $x$; a reduction algorithm has been constructed in Ref. [7].

Fig. 1. The generic class of two-loop on-shell diagrams with two masses. Solid lines have mass $M$, dashed lines mass $m$, and wavy lines are massless.

Fig. 2. The two-loop master integrals.

The first three-loop on-shell calculation with two different masses has been done by Laporta and Remiddi [8]. At three loops, there are three generic classes of diagrams in QCD (Fig. 3). Recently, three of us together with M. Steinhauser have demonstrated [9] that the corresponding Feynman integrals can be reduced to 27 master integrals (Figs. 4–9) (see also [10]). The reduction is performed by the C++ program Crusher [11] which implements the Laporta algorithm [12] to solve integration by parts identities [13]. This is done exactly at general $d$; simple polynomial operations are done by GiNaC [14], and simplification of rational expressions in $d$ and $x$ by Fermat [15]. On-shell mass and wave-function renormalization of a heavy quark (e.g., $b$) in QCD with another massive flavour (e.g., $c$) have been calculated at three loops. In the present paper, we present details of the calculation of the master integrals used in [9]. These integrals can be used in many other three-loop on-shell calculations.

Our results can also be used for another important kind of diagrams, namely, diagrams with two different non-zero masses and any number of external lines for their integration momenta; a class is generic if it contains a maximum number of lines (denominators); contracting some line(s) in a class, one obtains contracted classes.

3 In this paper, another integral was used as master instead of the last one in Fig. 2. It is, of course, easy to reduce this last integral to the master ones of Ref. [7], solve for this master integral, and then express all results via the integrals of Fig. 2.
with small momenta. If we expand in them, these diagrams reduce to vacuum integrals with two masses. And such integrals are particular cases of on-shell integrals considered in the present paper (the incoming leg and the outgoing one are attached to one and the same vertex). Such diagrams reduce to the master integrals in Figs. 4, 5. Therefore, the master integrals we are investigating here are also useful for another wide area of applications.
We shall use the Minkowski notation. All denominators will contain $-i0$. Loop integrals will be divided by $i\pi^{d/2}$ for each loop. For example,

\[
\begin{align*}
\mathcal{I}_{a} &= \frac{1}{i\pi^{d/2}} \int \frac{d^d k}{(M^2 - k^2 - i0)^a} = \frac{\Gamma(a - d/2)}{\Gamma(a)} M^{d-2a}, \\
\mathcal{I}_{a} &= \frac{\Gamma(a - d/2)}{\Gamma(a)} m^{d-2a}.
\end{align*}
\]

Powers of denominators are either written near the corresponding lines, or indicated by dots (if they are some specific small integers). The master integrals with 3 lines (Fig. 4) are products of (1.2), (1.3).
2 Two-loop sunset diagrams

The master integrals 4.4–4.7a (Fig. 6) are products of two-loop sunset diagrams (Fig. 10) and one-loop vacuum bubbles. The first sunset diagram can be expressed via Γ functions for any powers of denominators:

\[
\frac{\Gamma(d/2 - a_1)\Gamma(d/2 - a_2)\Gamma(a_1 + a_2 - d/2)}{\Gamma(a_1)\Gamma(a_2)\Gamma(a_3)} \times \frac{\Gamma(a_1 + a_2 + a_3 - d)\Gamma(2d - a_1 - a_2 - a_3)}{\Gamma(d - a_1 - a_2)\Gamma(3d/2 - a_1 - a_2 - a_3)} M^{3d - 2(a_1 + a_2 + a_3)}. \quad (2.1)
\]

Fig. 10. Two-loop sunset diagrams.

The non-trivial single-scale master integral (3.3 in Fig. 10) was investigated in Ref. [2]. It can be written as

\[
\frac{\Gamma^2(1 + \varepsilon)}{(1 - 2\varepsilon)(1 - 3\varepsilon)(2 - 3\varepsilon)} \times \left[ 3 \frac{1 - 6\varepsilon}{\varepsilon^2} + \frac{7}{\varepsilon} \frac{\Gamma(1 - \varepsilon)\Gamma^2(1 + 2\varepsilon)\Gamma(1 + 3\varepsilon)}{\Gamma^2(1 + \varepsilon)\Gamma(1 + 4\varepsilon)} + \frac{8}{3} \pi^2 2^{-6\varepsilon} \frac{\Gamma(1 + 2\varepsilon)\Gamma(1 + 3\varepsilon)}{\Gamma^5(1 + \varepsilon)} + 24\varepsilon^3 B_4(\varepsilon) \right] M^{2 - 4\varepsilon}, \quad (2.2)
\]

where

\[
B_4(\varepsilon) = \frac{8}{3\varepsilon^2(1 + 2\varepsilon)} {}_3F_2 \left( \begin{array}{c} 1, \frac{1}{2} - \varepsilon, \frac{1}{2} - \varepsilon \\ \frac{3}{2}, \frac{3}{2} + \varepsilon \end{array} ; 1 \right) - \frac{7}{24\varepsilon^4} \left( \frac{\Gamma(1 - \varepsilon)\Gamma^2(1 + 2\varepsilon)\Gamma(1 + 3\varepsilon)}{\Gamma^2(1 + \varepsilon)\Gamma(1 + 4\varepsilon)} - 1 \right) - \frac{\pi^2 2^{-6\varepsilon} \Gamma(1 + 2\varepsilon)\Gamma(1 + 3\varepsilon)}{3\varepsilon^2 \Gamma^5(1 + \varepsilon)} = 16 \text{Li}_4 \left( \frac{1}{2} \right) + \frac{2}{3} \log^2 2 \left( \log^2 2 - \pi^2 \right) - \frac{13}{180}\pi^4 + \mathcal{O}(\varepsilon). \quad (2.3)
\]
The expansion of $B_3(\varepsilon)$ up to $\mathcal{O}(\varepsilon^3)$ can be found in \cite{16}. The hypergeometric function can also easily be expanded in $\varepsilon$ with the help of the package HypExp \cite{17}.

The two master sunset integrals with two masses (Fig. 2) have been calculated up to $\mathcal{O}(\varepsilon^0)$ in Ref. \cite{18}, and up to $\mathcal{O}(\varepsilon^5)$ in Ref. \cite{19}.

Here we obtain exact results for them to $\mathcal{O}(\varepsilon^3)$. To this end we use the method of differential equations \cite{21}. The class of two-loop sunset diagrams with two masses has two master integrals. This leads to a system of coupled differential equations. The first one is

\[
\frac{d}{dx} = 2 \left( \frac{1}{x+1} + \frac{1}{x-1} \right) - 32\varepsilon M^4 \left( \frac{1}{x+1} + \frac{1}{x-1} \right) - \frac{2}{M^2} \left( \frac{2}{x} - \frac{1}{x+1} - \frac{1}{x-1} \right) + \frac{1}{M^2} \left( \frac{2}{x} - \frac{1}{x+1} - \frac{1}{x-1} \right),
\]

where the coefficients have already been expanded in $\varepsilon$ and only the leading term in $\varepsilon$ for each coefficient is written. As usual the integrals of contracted classes are assumed to be known and so are part of the inhomogeneous term of the differential equation. If the system is solved order by order in $\varepsilon$ the integral with two dots (3.1b) decouples from (2.4). The equation for this integral is

\[
\frac{d}{dx} = \frac{1}{x}.
\]

Note that here $\varepsilon$ is set to zero in all coefficients. Of course all integrals which appear in (2.4) are also present in this equation, but they only contribute at higher orders in $\varepsilon$. Looking at the structure of the coefficients in this system one can see that it is possible to get solutions for the master integrals in terms of harmonic polylogarithms \cite{22} (this is also true if one writes the coefficients

\footnote{they were also calculated up to $\mathcal{O}(\varepsilon)$ as series in $x$ up to $x^6$ \cite{20}.}
to arbitrary order in $\varepsilon$). We have used the package HPL \cite{23} to implement the integration of the differential equations.

After integrating there is one constant per order in $\varepsilon$ and per integral which is not determined. In the case of the integral 3.1 (Fig. 10) one constant can be determined in the limit $x \to 0$, where this integral reduces to 3.2. For the integral 3.1b the limit $x \to 0$ gives the correct result independently of the choice of the constant, as the constant in the integral is proportional to $x$ and drops out in this limit. To get this constant we use the limit $x \to 1$, where the resulting integral can be reduced to 3.3.

The result for the master integral 3.1 (Fig. 10) up to the finite part in $\varepsilon$ reads

$$\begin{align*}
\left( \begin{array}{c}
\int \\
\frac{d^d k}{2 \pi^d} \\
\end{array} \right) = M^{2-4\varepsilon} \Gamma^2(1 + \varepsilon) \left[ -\frac{1}{\varepsilon^2} \left( x^2 + \frac{1}{2} \right) \\
+ \frac{1}{\varepsilon} \left( 4x^2 H(0; x) - 3x^2 - \frac{5}{4} \right) + 2(x^2 - 1)^2 \left( H(-1, 0; x) - H(1, 0; x) - \frac{\pi^2}{6} \right) \\
- 4x^2(x^2 + 2)H(0, 0; x) + 14x^2 H(0; x) - 6x^2 - \frac{11}{8} + \mathcal{O}(\varepsilon) \right],
\end{align*}$$

(2.6)

where $H$ denote the harmonic polylogarithms. Up to this order they can of course be expressed in terms of logarithms and ordinary polylogarithms, but this gets impossible in higher orders in $\varepsilon$. We have calculated the diagram 3.1a (Fig. 10) (which can be reduced to 3.1b) up to order $\varepsilon^3$, but we refrain from presenting the result in a written form in this paper. Instead we refer to the web-site \cite{24}, where all our results can be found in the form of a Mathematica package. Our results agree with \cite{19}.

We also used another approach. The Mellin–Barnes representation of the massive one-loop self-energy is \cite{25}\footnote{For a simpler derivation, see \cite{26}.}

$$\begin{align*}
\left( \begin{array}{c}
\int \\
\frac{d^d k}{2 \pi^d} \\
\end{array} \right) &= \frac{1}{i \pi^{d/2}} \int \frac{d^d k}{[m^2 - k^2 - i0]^{a_1} [m^2 - (k + p)^2 - i0]^{a_2}} \\
&= \frac{m^{d-2(a_1+a_2)}}{\Gamma(a_1)\Gamma(a_2)} \left[ \frac{1}{2\pi i} \right. \\
&\times \left. \int_{-\infty}^{+i\infty} dz \Gamma(-z) \right. \\
&\times \left. \Gamma(a_1 + z)\Gamma(a_2 + z)\Gamma(a_1 + a_2 - d/2 + z) \right. \\
&\times \left. \frac{1}{\Gamma(a_1 + a_2 + 2z)} m^{-2z} \right],
\end{align*}$$

(2.7)
where the integration contour is chosen in such a way that poles of \( \Gamma \) functions with \(+z\) are to the left of it and of those with \(-z\) are to the right. We obtain

\[
\frac{M^{d-2a_3}m^{d-2(a_1+a_2)}}{\Gamma(a_1)\Gamma(a_2)\Gamma(a_3)} \frac{1}{2\pi i} \int_{-\infty}^{+\infty} dz \, x^{-2z} \times \Gamma(-z)\Gamma(a_3-d/2-z) \times \frac{\Gamma(a_1+z)\Gamma(a_2+z)\Gamma(a_1+a_2-d/2+z)\Gamma(d-a_3+2z)}{\Gamma(d-a_3+z)\Gamma(a_1+a_2+2z)}. \quad (2.8)
\]

This result is a particular case of [7].

3 Three-loop vacuum bubbles

The diagrams in the first row of Fig. 5 are vacuum bubbles. The first one, 4.1, can be expressed via \( \Gamma \) functions for any powers of denominators:

\[
\begin{align*}
\frac{a_3}{a_2} & = \frac{\Gamma(d/2-a_1)\Gamma(d/2-a_2)\Gamma(a_1+a_2-d/2)}{\Gamma(a_1)\Gamma(a_2)\Gamma(a_3)\Gamma(a_4)\Gamma(d/2)} \\
& \times \Gamma(a_1+a_2+a_3-a_4-d)\Gamma(a_1+a_2+a_4-d) \\
& \times \frac{\Gamma(a_1+a_2+a_3+a_4-3d/2)}{\Gamma(2(a_1+a_2-d)+a_3+a_4)} m^{3d-2(a_1+a_2+a_3+a_4)}. \quad (3.1)
\end{align*}
\]

The non-trivial single-scale master integral (4.2 in Fig. 5) was investigated in Ref. [2]:

\[
\begin{align*}
\frac{a_3}{a_2} & = \frac{4\Gamma^3(1+\varepsilon)}{3(1-\varepsilon)(1-2\varepsilon)(1-3\varepsilon)(2-3\varepsilon)} \left[ \frac{1-6\varepsilon}{\varepsilon^3} \\
& + \frac{7}{\varepsilon^2} \frac{\Gamma(1-\varepsilon)\Gamma^2(1+2\varepsilon)\Gamma(1+3\varepsilon)}{\Gamma^2(1+\varepsilon)\Gamma(1+4\varepsilon)} + 24\varepsilon^2 B_4(\varepsilon) \right] m^{4-6\varepsilon}, \quad (3.2)
\end{align*}
\]

where \( B_4(\varepsilon) \) is given by Eq. (2.3).
As in the case of the two-loop sunset diagrams, the vacuum bubble diagrams 4.3 and 4.3a can be calculated by solving the corresponding differential equations in terms of harmonic polylogarithms. We have used the solution of diagram 4.1 (see Eq. (3.1)) as initial condition in the limit $x \rightarrow 0$. Taking the limit $x \rightarrow 1$ we recover the expanded version of Eq. (3.2). For example,

$$
\begin{align*}
\Gamma(1) & = M^{4-6\varepsilon}\Gamma^3(1+\varepsilon) \left[ \frac{x^4 + 4x^2 + 1}{3\varepsilon^3} \right. \\
& - \frac{1}{\varepsilon^2} \left( 2x^2(x^2 + 2)H(0; x) - \frac{1}{6} (7x^4 + 32x^2 + 7) \right) \\
& + \frac{1}{\varepsilon} \left( 4x^2(3x^2 + 2)H(0, 0; x) - x^2(7x^2 + 16)H(0; x) \right. \\
& \left. + \frac{5}{12} (5x^4 + 32x^2 + 5) \right) + \mathcal{O}(1) \right]. 
\end{align*}
$$

(3.3)

The analytic results expanded up to $\mathcal{O}(\varepsilon^2)$ of all vacuum-diagrams depicted in Fig. (5) can be obtained on the aforementioned webpage.

For the vacuum bubble with two masses we obtain, using the Mellin–Barnes representation (2.7),

$$
\begin{align*}
\Gamma(1) & = \frac{M^{2(d-a_3-a_4)}m^{d-2(a_1+a_2)}}{\Gamma(a_1)\Gamma(a_2)\Gamma(a_3)\Gamma(a_4)\Gamma(d/2)} \frac{1}{2\pi i} \int_{-i\infty}^{+i\infty} dz \, z^{-2z} \\
& \times \Gamma(-z)\Gamma(a_3-d/2-z)\Gamma(a_4-d/2-z)\Gamma(a_3+a_4-d-z) \\
& \times \Gamma(a_3+a_4-d-2z) \\
& \times \frac{\Gamma(d/2+z)\Gamma(a_1+z)\Gamma(a_2+z)\Gamma(a_1+a_2-d/2+z)}{\Gamma(a_1+a_2+2z)} 
\end{align*}
$$

(3.4)

(this is a particular case of a more general result recently derived in [27]). This diagram is, of course, symmetric with respect to $a_{1,2} \leftrightarrow a_{3,4}$, $M \leftrightarrow m$, though this is not evident in (3.3).

4 Three-loop sunset diagrams

Here we consider three-loop on-shell sunsets with masses $M, m, m, 0$ (Fig. 7). The first of them has been calculated up to $\mathcal{O}(\varepsilon^3)$ in Ref. [28], though only the $\mathcal{O}(\varepsilon^1)$ term is presented in the paper.
Doing a naive reduction to master integrals of all three-loop on-shell sunsets with masses $M, m, m, 0$ one finds four “master integrals”. As already noticed in [28], one of these integrals decouples completely when setting up a higher order differential equation for the integral 4.8 (Fig. 7). We have performed a reduction for all classes of the different master integrals presented in this paper. It turns out that in the course of the reduction of the class to which the integral 5.1 (Fig. 8) belongs, an equation is generated which contains no five-line master integrals and connects the integral 4.1 (Fig. 5) and one of the integrals from the class discussed in this section. So it gets manifest that one of the four integrals found by the naive reduction is reducible with integration by part identities.

For example, for 4.8 we obtain

$$= M^{4-6\varepsilon} \Gamma^3(1+\varepsilon) \left[ \frac{x^2(x^2+2)}{3\varepsilon^3} \right.$$

$$\left. + \frac{1}{\varepsilon^2} \left( -2x^2(x^2+1)H(0;x) + \frac{1}{6}(7x^4+15x^2-1) \right) 
+ \frac{1}{\varepsilon} \left( 4x^2(3x^2+1)H(0,0;x) - 7x^2(x^2+1)H(0;x) 
+ \frac{1}{36}(75x^4+213x^2-35) \right) + \mathcal{O}(1) \right].$$

(4.1)

The analytic results for all three master integrals in Fig. 7 up to order $\varepsilon$ are presented on the aforementioned webpage.

Using the Mellin–Barnes representation (2.7), we obtain

$$= \frac{M^{2(d-a_3-a_4)}m^{d-2(a_1+a_2)}\Gamma(d/2-a_3)}{\Gamma(a_1)\Gamma(a_2)\Gamma(a_3)\Gamma(a_4)}$$

$$\times \frac{1}{2\pi i} \int_{-i\infty}^{+i\infty} dz \frac{x^{-2z}\Gamma(a_3 - d/2 - z)\Gamma(a_3 + a_4 - d - z)}{\Gamma(d/2 + z)}$$

$$\times \frac{\Gamma(a_1 + z)\Gamma(a_2 + z)\Gamma(a_1 + a_2 - d/2 + z)}{\Gamma(d - a_3 + z)\Gamma(3d/2 - a_3 - a_4 + z)\Gamma(a_1 + a_2 + 2z)}. \quad (4.2)$$
5 Master integrals with 5 lines

We have calculated the master integrals 5.1 and 5.1a (Fig. 8) analytically up to $O(\varepsilon)$ with the differential equations method. The integrals 5.4 and 5.4a are obtained with the same method up to $O(\varepsilon^2)$. The integrals 5.2, 5.2a, 5.3, 5.3a are obtained up to $O(\varepsilon^{-1})$ with that method.

For the two classes 5.1 and 5.4 the differential equations have a structure with which it is possible to integrate them with the help of harmonic polylogarithms. So in principle, if the initial conditions are known for the corresponding integrals, solutions can be obtained to arbitrary order in $\varepsilon$. This is different for the classes 5.2 and 5.3. Here the pole structures of the differential equations do not only contain poles of the form $1/x$ and $1/(1 \pm x)$, but in addition the poles $1/(1 \pm 2x)$ (for 5.2) and $1/(1 \pm x/2)$ (for 5.3). It is not possible to integrate the differential equations in terms of the usual harmonic polylogarithms with three weight functions, Nevertheless we were able to integrate all equations for these integrals up to order $\varepsilon^{-1}$. The $\varepsilon^0$ parts of the master integrals 5.3 and 5.3a were obtained analytically using Mellin-Barnes representation, see below.

To get a result in higher orders in $\varepsilon$ for the integrals of the classes 5.2 and 5.3 we calculated the integrals in an expansion around $x = 0$. With the help of the ansatz

$$\sum c_{ijk} \varepsilon^i x^j \log^k x$$

(5.1)

for the master integrals, the differential equations can be expanded in $\varepsilon$ and $x$. As a result the differential equations reduce to algebraic equations for the coefficients $c_{ijk}$. In every order in $\varepsilon$ there is one constant $c_{ijk}$ which can not be determined with this procedure.

A problem which can arise when determining these remaining constants is the fact that it may happen that the initial condition for some integrals is fulfilled for the corresponding constant being arbitrary. In the case of the class 5.3 this problem occurs when one chooses the two integrals depicted in the third line of Fig. 8 as master integrals. Sometimes one can determine the constants via analytic considerations. In our case this was not possible. The problem can be solved by switching to another master integral basis and replacing the integral with the dot with the integral 5.3b:
\[
\frac{1}{(i\pi^{d/2})^3} \int d^d l_1 d^d l_2 d^d l_3 \frac{(l_3 - p)^2}{[m^2 - l_3^2] \left[ m^2 - (l_2 - l_1)^2 \right]^{3} \left[ M^2 - l_3^2 \right] \left[ M^2 - (l_3 - l_1)^2 \right]} ,
\]

where \( p^2 = M^2 \) denotes the on-shell external momentum. For this particular choice of master integrals it is possible to determine all constants in the ansatz (5.1) using the corresponding initial conditions at \( x = 0 \).

For the class 5.2 no basis of master integrals exists, where all constants can be determined via the initial conditions. In every order in \( \varepsilon \) the coefficient of the \( x^3 \)-term in the \( x \)-expansion of the integral 5.2 remains undetermined. To get this constant we calculated the integral by means of the method of regions [29] up to the third order in \( x \). After having determined the constant in this way all other orders in \( x \) are fixed.

On the website mentioned earlier we present the analytic results for the integrals depicted in Fig. (8). We also give expansions up to \( \mathcal{O}(x^{14}) \) for the integrals depicted in the second and third line of the figure up to \( \mathcal{O}(\varepsilon) \).

For the diagrams 5.1 and 5.1a in Fig. 8 we can obtain a one-fold Mellin–Barnes representation, using (2.7):

\[
\begin{align*}
&= M^{2(d-a_3-a_4-a_5)} m^{d-2(a_1+a_2)} \\
&\times \frac{\Gamma(d/2 - a_3)\Gamma(d/2 - a_4)\Gamma(a_3 + a_4 - d/2)}{\Gamma(a_1)\Gamma(a_2)\Gamma(a_3)\Gamma(a_4)\Gamma(a_5)\Gamma(d - a_3 - a_4)} \frac{1}{2\pi i} \int_{-i\infty}^{+i\infty} dz \ x^{-2z} \\
&\times \Gamma(-z)\Gamma(a_3 + a_4 + a_5 - d - z)\Gamma(a_1 + z)\Gamma(a_2 + z) \\
&\times \frac{\Gamma(a_1 + a_2 - d/2 + z)\Gamma(2(d - a_3 - a_4) - a_5 + 2z)}{\Gamma(3d/2 - a_3 - a_4 - a_5 + z)\Gamma(a_1 + a_2 + 2z)} .
\end{align*}
\]

For the diagrams 5.2, 5.2a, 5.3 and 5.3a in Fig. 8, we have to use (2.7) twice. Therefore, we obtain two-fold Mellin–Barnes representations:
which implements sector decomposition. The results were also checked numerically using the program FIESTA \textsuperscript{[31]} and MB.m [32], implemented in Mathematica. At the last step, one-fold MB integrals were evaluated by closing the integration contour and summing up series. The expansions in $x$ agree with those obtained from differential equations. The results were also checked numerically using the program FIESTA \textsuperscript{[31]} which implements sector decomposition, where various algorithms of sector decomposition developed in Refs. [35,36,34] are implemented.
For the calculations presented in [9] we also needed the $\varepsilon^1$ coefficients of the five line master integrals. As discussed above we were able to calculate all of them as series in $x$ but not all could be evaluated analytically. Let us now describe how we can get a numerical solution for these integrals, including the $\varepsilon^1$ coefficient. We also used this method as a numerical check of our analytical results.

We choose integral 5.3 (Fig. 8) with all indices equal to 1 as an example. The starting point is the MB representation, Eq. (5.5), of this integral. Inserting $d = 4 - 2\varepsilon$ and $a_i = 1$ we obtain

$$
\frac{M^{2-6\varepsilon}}{(2\pi i)^2} \int_{-i\infty}^{+i\infty} dz_1 \int_{-i\infty}^{+i\infty} dz_2 \, x^{-2\varepsilon - 2z_1} 
\times \Gamma(-z_1) \Gamma^2(1 + z_1) \Gamma(\varepsilon + z_1) \Gamma(-z_2) \Gamma^2(1 + z_2) \Gamma(\varepsilon + z_2) 
\times \Gamma(2 + 2z_1) \Gamma(2 + 2z_2) \Gamma(3 - 2\varepsilon + z_1 + z_2) 
\times \Gamma(-1 + \varepsilon - z_1 - z_2) \Gamma(3 - 2\varepsilon + 2z_1 + 2z_2).$$

(5.6)

The next step is the resolution of the $\varepsilon$ singularities using the algorithm described in [30,33]. Our integral is decomposed into five analytical expressions, two one-dimensional MB integrals and one two-dimensional one, which contains the same integrand as Eq. (5.6) but with modified integration contours. The integrand expanded in $\varepsilon$ reads

$$
F = -\frac{(x^2)^{-z_1}}{\Gamma \left( z_1 + \frac{3}{2} \right) \Gamma \left( z_1 + z_2 + 3 \right) \Gamma(2z_2 + 2)} 
\times 2^{2z_2 + 1} \Gamma(-z_1) \Gamma(z_1) \Gamma(z_1 + 1) \Gamma(-z_1 - z_2 - 1) \Gamma(-z_2) 
\times \Gamma(z_2) \Gamma^2(z_2 + 1) \Gamma \left( z_1 + z_2 + \frac{3}{2} \right) \Gamma(z_1 + z_2 + 2) 
\times \left\{-1 + \varepsilon \left[ 2 \log x + 2 \log 2 - \psi(z_1) - \psi(-z_1 - z_2 - 1) - \psi(z_2) 
+ \psi \left( z_1 + z_2 + \frac{3}{2} \right) + \psi(z_1 + z_2 + 2) - 2\psi(z_1 + z_2 + 3) \right] \right\}.

(5.7)

To evaluate the integral we close the integration contours and sum up the residues. Since $x^2$ appears with the power $-z_1$ and we are interested in an expansion for small $x$ we have to close the contour for $z_1$ to the left. We are free in the way how we close the contour for $z_2$ and choose the right side, considering the $\Gamma$ functions $\Gamma(-z_2)$ and $\Gamma(1 - z_1 - z_2)$. The integral is then given as the sum of the residues in the points $z_2 = n$ and $z_2 = -z_1 + 1 + n$ for positive integers $n$. The expressions for these residues read (we write only the $\varepsilon^0$ part here):
\[ A_1(n) = -\text{Res}(F, z_2 = n) = \frac{2^{2n+1} (x^2)^{-z_1}}{n \pi (n + z_1 + 1)} \times \frac{\Gamma^2(n + 1) \Gamma(1 - z_1) \Gamma(-n - z_1 + 1) \Gamma(-z_1) \Gamma^2(z_1) \Gamma(z_1 + 1)}{\Gamma(2n + 2) \Gamma \left( z_1 + \frac{3}{2} \right) \Gamma(n + z_1 + 1) \Gamma(n + z_1 + 3) \times \Gamma(n + z_1) \Gamma \left( n + z_1 + \frac{3}{2} \right) \Gamma(n + z_1 + 2) \sin(\pi(n + z_1))}, \quad (5.8) \]

\[ A_2(n) = -\text{Res}(F, z_2 = -z_1 + 1 + n) = \frac{-2^{2n} (x^2)^{-z_1}}{2^{2z_1+1} n (n - z_1 - 1)} \times \frac{\Gamma \left( n + \frac{1}{2} \right) \Gamma(n + 1) \Gamma(1 - z_1) \Gamma^2(n - z_1) \Gamma(-z_1) \Gamma^2(z_1) \Gamma(z_1 + 1)}{\Gamma(n) \Gamma(n + 2) \Gamma(2n - 2z_1) \Gamma \left( z_1 + \frac{3}{2} \right)}. \quad (5.9) \]

Now we take the residues in the points \( z_1 = -n - \frac{3}{2} - m \) and \( z_1 = -m \) with positive integers \( m \). We have to choose \( m \geq 0 \) or \( m \geq 1 \), depending on how the integration contour passes the poles of the \( \Gamma \) functions.

Thus we get a two-fold sum,

\[ \sum_n \sum_m f_i(m, n), \quad (5.10) \]

the summands \( f_i \) consisting of rational functions of \( m, n \) and \( \Gamma, \psi \) and trigonometric functions whose arguments are linear combinations of \( m, n \).

To check our analytical series expansion we proceed as follows. Some of the summands are proportional to \((x^2)^{m+n}\) and some to \((x^2)^m\). In the first case we only need to sum up a finite number of terms to get an expansion to a given order in \( x \). In the second case the sum is an expansion in \( x \) where the coefficients are infinite sums in \( n \). We evaluate these coefficients to a finite order given by the required numerical precision.

The one-fold sums contributing to the integral 5.3 are special cases of the described procedure. However, there is one partial sum which does not depend on \( x \) and shows quite a bad convergence behaviour. In this case we use the method of nonlinear sequence transformations (see Refs. [37,38] and references therein) to improve the convergence.

As a result we finally get an expansion for the integral 5.3 in powers of \( x \) with numerical coefficients. Up to the order \( x^5 \) it reads
\[ = M^{2-6\varepsilon} e^{-3\gamma_E \varepsilon} \left\{ \frac{1}{\varepsilon^3} (-0.66667 - 0.33333 x^2) \right\} + \frac{1}{\varepsilon^2} \left[ -3.33333 + (-2.00000 + 2.00000 \log x) x^2 \right] + \frac{1}{\varepsilon} \left[ -13.60147 + (-0.57606 + 12.00000 \log x - 2.00000 \log^2 x) x^2 \right.
\]
\[ + (-5.03987 + 3.00000 \log x - 2.00000 \log^2 x) x^4 \right] + [-52.02282 \\
+ (31.35527 + 28.61586 \log x - 12.00000 \log^2 x + 1.33333 \log^3 x) x^2 \\
- 52.63789 x^3 \\
+ (13.71171 - 0.92026 \log x - 5.00000 \log^2 x + 4.00000 \log^3 x) x^4 \\
+ 10.52758 x^5] + \varepsilon \left[ -153.61196 + (149.09532 + 91.43326 \log x \\
- 28.61586 \log^2 x + 8.00000 \log^3 x - 0.66667 \log^4 x) x^2 \\
+ (-94.12475 + 210.55156 \log x) x^3 \\
+ (-106.98907 + 20.56599 \log x - 6.01454 \log^2 x + 6.00000 \log^3 x \\
- 4.66667 \log^4 x) x^4 + (-18.37249 - 42.11031 \log x) x^5 \right]\right\}, \quad (5.11)

where we arbitrarily display five digits. We determined the coefficients with a relative error of at least \(10^{-8}\). The result numerically agrees with the analytical expansion obtained with the differential equation method.

To find numerical solutions for the master integrals we insert fixed values for \(x\) in the sum (5.10) and sum it up numerically. As a further check we use the numerical integration routine of MB. The summation procedure takes more computing time but its advantage is that the errors are smaller than those we get from the numerical integration.

We used this method to find numerical expansions and also numerical results for fixed values of \(x\) for the master integrals 5.2, 5.2a, 5.3 and 5.3a. Let us finally mention the differences in the calculation of these. Diagram 5.2 has two loops with the light quark mass. Therefore the MB integrand is proportional to \(x^{s_1+s_2}\) and we have no freedom to choose how we close the integration contours. On the other hand, all summands contain the parameter \(x\) and thus the calculation is faster. Integrals 5.2a and 5.3a contain an additional power on one denominator. This changes the arguments of the \(\Gamma\) functions and we have less MB integrals to consider. Their complexity is comparable to that of the undotted integrals.
6 Master integrals with 6 lines

Contrary to the integrals with five lines, the ones depicted in Fig. 9 pose no difficulties when solving them with the help of the differential equation method. The integrals where some parts of the ε-expansion are only known as expansions in x (see the previous Section) do not appear as contracted classes in the differential equations. Furthermore, the poles of the coefficients in the differential equations are only of the form 1/x and 1/(1±x). We can therefore get closed solutions of the equations in terms of harmonic polylogarithms.

To obtain the integration constants we use the boundary condition at x = 1. The corresponding values can be found in [5] up to O(ε). We obtain for 6.1, 6.2, 6.3

\[
\begin{align*}
6.1 & = M^{-6\varepsilon} \Gamma^3 (1 + \varepsilon) \left( \frac{1}{6\varepsilon^3} + \frac{3}{2\varepsilon^2} - \frac{2\pi^2 - 55}{6\varepsilon} + O(1) \right), \\
6.2 & = M^{-6\varepsilon} \Gamma^3 (1 + \varepsilon) \left( \frac{1}{3\varepsilon^3} + \frac{7}{3\varepsilon^2} + \frac{31}{3\varepsilon} + O(1) \right), \\
6.3 & = M^{-6\varepsilon} \Gamma^3 (1 + \varepsilon) \left( \frac{2\zeta_3}{\varepsilon} + O(1) \right). 
\end{align*}
\]

The results for the master integrals with six lines up to O(ε) can be obtained on the website.

We were able to derive a one-fold MB representation for the master integral 6.1 in Fig. 9. Using (2.7) we get a two-loop on-shell integral with a single non-integer index −z. It can be reduced to trivial ones by integration by parts, and we obtain
\[
\frac{\Gamma(-z)\Gamma(a_1 + z)\Gamma(a_2 + z)\Gamma(a_1 + a_2 - 2 + \varepsilon + z)}{(1 - 2\varepsilon + z)\Gamma(a_1 + a_2 + 2z)} \left[ \frac{\Gamma(\varepsilon)\Gamma(2 - 2\varepsilon + 2z)}{\Gamma(-z)\Gamma(2 - 2\varepsilon + z)} - \frac{\Gamma(\varepsilon)\Gamma(1 - \varepsilon)\Gamma(2 - 4\varepsilon + 2z)}{\Gamma(1 - 2\varepsilon)\Gamma(2 - 3\varepsilon + z)} \right] + \Gamma(1 - \varepsilon) \frac{\Gamma(\varepsilon - z)\Gamma(2\varepsilon - z)\Gamma(1 - \varepsilon + z)\Gamma(2 - 4\varepsilon + 2z)}{\Gamma(-z)\Gamma(2 - 2\varepsilon + z)\Gamma(2 - 3\varepsilon + z)} \right].
\]

(6.2)

7 Conclusion

The status of our knowledge of the master integrals is summarized in the Tables 1–4. Here DE means that a result is known analytically, exactly in \(x\), and has been obtained by the method of differential equations; MB — the same, but using Mellin–Barnes representation; \(x\) — expansion of the result (up to \(x^{14}\)) is known analytically, from differential equations (and a numerical value can be calculated for any \(x\) by integrating the MB representation numerically); a reference means that a result has been obtained by others.

Table 1

Two-loop sunset master integrals (Sect. 2)

| \(\varepsilon^{-2}\) | \(\varepsilon^{-3}\) | \(\varepsilon^{-4}\) | \(\varepsilon^{-5}\) | \(\varepsilon^{-6}\) |
|---------------------|---------------------|---------------------|---------------------|---------------------|
| \(3.3\)             | \(3.3\)             | \(3.1, 3.1a\)       | \(3.1, 3.1a\)       | \(3.1, 3.1a\)       |
| \(3.1\)             | \(3.1\)             | \(3.1\)             | \(3.1\)             | \(3.1\)             |
| \(3.1a\)            | \(3.1a\)            | \(3.1a\)            | \(3.1a\)            | \(3.1a\)            |
| \(3.2\)             | \(3.2\)             | \(3.2\)             | \(3.2\)             | \(3.2\)             |

| \(3.3\)             | \(3.3\)             | \(3.3\)             | \(3.3\)             | \(3.3\)             |
| \(3.3a\)            | \(3.3a\)            | \(3.3a\)            | \(3.3a\)            | \(3.3a\)            |
| \(3.4\)             | \(3.4\)             | \(3.4\)             | \(3.4\)             | \(3.4\)             |
| \(3.4a\)            | \(3.4a\)            | \(3.4a\)            | \(3.4a\)            | \(3.4a\)            |
| \(3.5\)             | \(3.5\)             | \(3.5\)             | \(3.5\)             | \(3.5\)             |
| \(3.5a\)            | \(3.5a\)            | \(3.5a\)            | \(3.5a\)            | \(3.5a\)            |
| \(3.6\)             | \(3.6\)             | \(3.6\)             | \(3.6\)             | \(3.6\)             |
| \(3.6a\)            | \(3.6a\)            | \(3.6a\)            | \(3.6a\)            | \(3.6a\)            |

These master integrals can be used for calculating any three-loop diagrams with two legs of a massive particle (with mass \(M\)) both of which are on the mass shell, and there is a loop of another massive particle (with mass \(m\)). They can be downloaded from [24] in the form of Mathematica files. The first physical application, namely the influence of \(m_c \neq 0\) on the on-shell mass of the \(b\) quark and its wave-function renormalization constant, has already been published [9]. We plan to use these results in some further problems. A subset of master integrals considered here is also necessary for another...
kind of problems — diagrams with any number of external lines having small momenta and containing loops of two different massive particles. There are several interesting physical problems which involve such diagrams.

We are grateful to M. Steinhauser for collaboration [9], and to P. Mastrolia and E. Remiddi for providing the complete results of Refs. [19,28].
