Ascites Due to Subserosal Type of Eosinophilic Gastroenteritis: A Case Report

Hasan S. Mahmoud

INTRODUCTION

Eosinophilic gastroenteritis (EGE) is a rare condition, it is defined as a disorder primarily affecting the gastrointestinal tract with eosinophil-rich inflammation, in the absence of known causes of eosinophilia (e.g. drug reactions, parasitic infections or malignancy) [1]. Three different forms of EGE can be distinguished: mucosal disease, muscle layer disease and subserosal disease. The symptoms of EGE are related to the layer involved. Mucosal disease is the most common form and presents with nonspecific symptoms such as abdominal pain, nausea, vomiting, diarrhea or malabsorption. The second form, muscle layer disease, is a more serious form that presents with symptoms due to intestinal obstruction. The third form, subserosal disease, is uncommon and presents with ascites [2-3].

CASE REPORT

51 years old male patient presented by abdominal pain, mainly central and upper abdominal, of gradual onset and intermittent course of two weeks duration. It was colicky in nature not referred or radiated, moderate in severity, not related to meal. No other upper gastrointestinal symptoms. Also patient suffered from diarrhea of gradual onset and intermittent course of the same duration, five time per day, yellow offensive in odour, no blood or tenesmus with little mucous. No other lower GI symptoms or fever. Stool analysis showed presence of pus cell 15-20, RBC 25-30, mucous (+), bacteria (+++); G –ve enterococci and E. Histolytica cyst so patient received ciprofloxacin and tinidazole and diloxanide furoate followed by complete improvement of diarrhea with normal follow up stool analysis. Patient suffered previously from diarrhea twice; 2 and 1.5 years ago, relieved also by ciprofloxacin. Examination showed that general, head and neck, upper and lower limbs, chest and heart and neurological examination were clinically free. Abdominal examination
by inspection it showed just diffuse abdominal enlargement with full flanks. No organomgaly and positive shifting dullness indicating moderate amount of free ascites. Investigations including complete blood count and serum IgE level showed leucocytosis and eosinophilia with marked elevation of serum Ig E level; this is illustrated in table 1. Chemical laboratory investigation showed that total serum protein 5.63 g/dL, serum albumin 3.44 g/dL, serum creatinine 1.1 mg/dL and blood urea 22 mg/dL. Total serum bilirubin was 0.3 mg/dL and normal liver enzymes. Abdominal US and CT scan showed marked amount of free ascites; this is shown in figure 1, otherwise normal findings were detected. Diagnostic aspiration was done for peritoneal fluid study, cytological and pathological examination. Ascitic fluid study showed that it was turbid and yellow in color. Its protein level was 5.6 g/dl, ascitic albumin was 3.24 g/dl and total WBC was 13100 cell/ml with differential count showed that eosinophils represent 88%, Macrophages 5%, lymphocytes 5% and polymorphs 2%. Z.N. stained film for T.B was negative. Serum ascitic albumin gradient was 0.2 g/dL indicating non-portal hypertension cause. Pathological and cytopathological examination of the films and sections from the block prepared from the centrifugate of the fluid revealed scattered red cells and lymphocytes, few mesothelial cells and eosinophilic proteinaceous material. No evidence of cytopathological atypia or malignancy; this is shown in figure 2. Patient refused to do endoscopic examination at all. Patient treated with prednisolone 40 mg/ day for two weeks and follow up abdominal US was done with complete disappearance of ascites; this is shown in figure 3. Then we started gradual withdrawal of corticosteroid with no appearance of ascites again. Peripheral eosinophil counts reached normal value, 2%, and Serum Ig E also showed normal level, 89 IU/ml, after one month of therapy.

## DISCUSSION

EGE is an uncommon disease characterized by eosinophilic infiltration in the gastrointestinal tract. The infiltration may involve one or more layers of the gastrointestinal wall and other abdominal organs. The pathogenesis of this disease is poorly understood, but speculation has focused on the selective release of eosinophil major proteins leading to the intestinal epithelial damage. Keshavarzian et al. demonstrated that the number of activated granulated eosinophils in the mucosa correlated with the severity of EGE. Several reports have pointed to a possible role of allergies to food and other allergens, while other investigators have refuted an allergic reaction as the etiology of this disease. In the current case, Ig E level was markedly elevated and decreased to normal value after therapy, supporting the allergic theory.

In a retrospective study of 40 patients, the most common symptoms were abdominal pain, nausea, vomiting, and diarrhea. In that study, the percentage of involving mucosal layer, muscle layer and subserosal disease were 58%, 30% and 12% respectively.

| Parameter   | Value            |
|-------------|------------------|
| RBC         | 6.5 × 10^6 /μL   |
| HGB         | 16 g/dL          |
| PLT         | 436 × 10^3 /μL   |
| WBC         | 29.2 × 10^3 /μL  |
| eosinophils | 27%              |
| neutrophils | 65%              |
| lymphocytes | 8%               |
| Serum Ig E  | 2,805 IU/mL      |

Table 1 Complete blood count and Ig E level before treatment.
Talley et al. reported that the patients with subserosal disease could be distinguished from the other two groups by clinical symptoms (abdominal bloating, ascites), higher eosinophils counts, and their dramatic responses to steroid therapy. The diagnostic feature of subserosal disease is a marked eosinophilia, up to 88 percent, in the ascitic fluid. In the current case report, patient presented with moderate ascites and high eosinophilic count in the ascitic fluid. This picture may be confused with cirrhotic ascites or abdominal carcinomatosis. Fortunately, marked eosinophilia in the ascites is an important clue to get the diagnosis of subserosal EGE.

Hypereosinophilia in peripheral blood is present in 20-90% of patients with EGE. Thus, the absence of peripheral hypereosinophilia should not exclude the diagnosis of EGE in patients with unexplained gastrointestinal symptoms. Radiologically, the hallmark of EGE is the thickening of mucosal folds demonstrated by barium study, computerized tomography, or ultrasound, depending on the severity and layer(s) involved. However, similar thickening may also be seen in Menetrier's disease, lymphoma, Crohn's disease, and granulomatous disease. Thus, the thickening of bowel wall is not specific for EGE.

The endoscopic appearance in EGE is also nonspecific, including erythematous, friable, nodular, and occasional ulcerative changes. The definite diagnosis of EGE must fulfill the following criteria: (1) the presence of gastrointestinal symptoms; (2) demonstration of eosinophilic infiltration of one or more areas of the GI tract on biopsy; (3) no evidence of parasitic or extraintestinal disease. So the diagnosis of this case was established by symptoms, eosinophilic count in the ascitic fluid, and marked elevation of the eosinophilic count in the ascitic fluid. So decision for treatment was taken and patient started steroid therapy.

In this case, patient was treated with steroid therapy for two weeks and ascites disappeared completely, then gradual withdrawal of the drug was taken. Follow up abdominal US after one and two month of stoppage of treatment revealed no ascites. In general, the clinical response of EGE to steroid treatment is usually dramatic, but improvement usually occurs within two weeks regardless of the layer of bowel involved. But some patients require more prolonged therapy (up to several months) to induce resolution of symptoms. Patients with refractory relapsing disease may require long-term low-dose steroids or immunosuppressive therapy.

In conclusion, subserosal type of EGE presenting as ascites is a rare disease. High eosinophilic count in ascitic fluid study is helpful in the diagnosis of EGE with subserosal involvement. Response to steroid therapy is marvellous.
