Abstract

Several major histocompatibility complex class I (MHC-I) alleles are associated with lower viral loads and slower disease progression in human immunodeficiency virus (HIV) and simian immunodeficiency virus (SIV) infections. Immune-correlates analyses in these MHC-I-related HIV/SIV controllers would lead to elucidation of the mechanism for viral control. Viral control associated with some protective MHC-I alleles is attributed to CD8\(^+\) T-cell responses targeting Gag epitopes. We have been trying to know the mechanism of SIV control in multiple groups of Burmese rhesus macaques sharing MHC-I genotypes at the haplotype level. Here, we found a protective MHC-I haplotype, 90-010-ld (D), which is not associated with dominant Gag-specific CD8\(^+\) T-cell responses. Viral loads in five D\(^+\) animals became significantly lower than those in our previous cohorts after 6 months. Most D\(^+\) animals showed predominant Nef-specific but not Gag-specific CD8\(^+\) T-cell responses after SIV challenge. Further analyses suggested two Nef-epitope-specific CD8\(^+\) T-cell responses exerting strong suppressive pressure on SIV replication. Another set of five D\(^+\) animals that received a prophylactic vaccine using a Gag-expressing Sendai virus vector showed significantly reduced viral loads compared to unvaccinated D\(^+\) animals at 3 months, suggesting rapid SIV control by Gag-specific CD8\(^+\) T-cell responses in addition to Nef-specific ones. These results present a pattern of SIV control with involvement of non-Gag antigen-specific CD8\(^+\) T-cell responses.

Introduction

Virus-specific CD8\(^+\) T-cell responses play a central role in the control of human immunodeficiency virus (HIV) and simian immunodeficiency virus (SIV) replication [1,2,3,4,5]. Genetic diversities of HLA or major histocompatibility complex class I (MHC-I) result in various patterns of CD8\(^+\) T-cell responses in HIV-infected individuals. Cumulative studies on HIV infection have indicated the association of MHC-I genotypes with higher or lower viral loads [6,7,8,9,10]. In some MHC-I alleles associating with lower viral loads and slower disease progression, certain CD8\(^+\) T-cell responses restricted by these MHC-I molecules have been shown to be responsible for HIV control [11,12,13]. In rhesus macaque AIDS models, Mamu-A*01, Mamu-B*08, and Mamu-B*17 are known as protective alleles, and macaques possessing these alleles tend to show slower disease progression after SIVmac251/SIVmac239 challenge [14,15,16,17].

Recent studies have indicated great contribution of CD8\(^+\) T-cell responses targeting Gag epitopes to reduction in viral loads in HIV/SIV infection [18,19,20,21]. Viral control associated with some protective MHC-I alleles is attributed to Gag epitope-specific CD8\(^+\) T-cell responses [22,23,24]. For instance, CD8\(^+\) T-cell responses specific for the HLA-B*57-restricted Gag240–249 TW10 and HLA-B*27-restricted Gag263–272 KK10 epitopes exert strong suppressive pressure on HIV replication and frequently select for an escape mutation with viral fitness costs, leading to lower viral loads [22,24,25,26,27]. On the other hand, CD8\(^+\) T-cell responses targeting SIV antigens other than Gag, such as Mamu-B*06- or Mamu-B*17-restricted Vif and Nef epitopes, have been indicated to exert strong suppressive pressure on SIV replication [28,29,30,31,32,33]. Accumulation of our knowledge on the potential of these non-Gag-specific as well as Gag-specific CD8\(^+\) T-cell responses for HIV/SIV control should be encouraged for elucidation of viral control mechanisms.
We have been examining SIVmac239 infection in multiple groups of Burmese rhesus macaques sharing MHC-I genotypes at the haplotype level and indicated an association of MHC-I haplotypes with AIDS progression [21,34]. In our previous study, a group of macaques sharing MHC-I haplotype 90-120-In (A) induced dominant Gag-specific CD8+ T-cell responses and tended to show slower disease progression after SIVmac239 challenge [21]. Prophylactic immunization of these A+ macaques with a DNA vaccine prime and a Gag-expressing Sendai virus (SeV-Gag) vector boost resulted in SIV control based on Gag-specific CD8+

Figure 1. Plasma viral loads after SIVmac239 challenge in unvaccinated macaques. Plasma viral loads (SIV gag RNA copies/ml plasma) were determined as described previously [35]. The lower limit of detection is approximately 4 × 10⁵ copies/ml. (A) Changes in plasma viral loads after challenge in unvaccinated macaques possessing MHC-I haplotype D. (B) Changes in geometric means of plasma viral loads after challenge in five unvaccinated D+ animals in the present study and twenty D animals in our previous cohorts [21]. Three of twenty D- animals were euthanized because of AIDS before 12 months, and we compared viral loads between D+ and D- animals until 12 months. (C) Comparison of plasma viral loads at 3 months (left panel), 6 months (middle panel), and 9 months (right panel) between the unvaccinated D+ and the D- animals. Viral loads at 6 months and 9 months in D+ animals were significantly lower than those in the latter D- animals (p = 0.0360 at 6 months and p = 0.0135 at 9 months by t-test).

doi:10.1371/journal.pone.0054300.g001
T-cell responses [35,36]. Accumulation of data on interaction between virus replication and T-cell responses in multiple groups of macaques sharing individual MHC-I haplotypes would provide great insights into our understanding of the mechanism for HIV/SIV control.

In the present study, we investigated SIVmac239 infection of a group of Burmese rhesus macaques possessing the MHC-I haplotype 90-010-Id (D), which was not associated with dominant Gag-specific CD8+ T-cell responses. These animals had persistent viremia in the early phase but showed significant reduction of viral loads around 6 months after SIV challenge. Most D+ animals showed predominant Nef-specific but not Gag-specific CD8+ T-cell responses. This study presents a protective MHC-I haplotype, indicating the potential of non-Gag antigen-specific CD8+ T-cell responses to contribute to SIV control.

Materials and Methods

Ethics Statement

Animal experiments were carried out in National Institute of Biomedical Innovation (NIBP) and Institute for Virus Research in Kyoto University (IVRKU) after approval by the Committee on the Ethics of Animal Experiments at NIBP, IVRKU, and National Institute of Infectious Diseases. To prevent viral transmission, animals were housed in individual cages allowing them to make sight and sound contact with one another, where the temperature was kept at 25°C with light in 12 hours per day. Animals were fed with apples and commercial monkey diet (Type CMK-2, Clea Japan, Inc. Tokyo). Blood collection, vaccination, and SIV challenge were performed under ketamine anesthesia. The endpoint for euthanasia was determined by typical signs of AIDS including reduction in peripheral CD4+ T-cell counts (less than 200 cells/μl), 10% loss of body weight, diarrhea, and general weakness. At euthanasia, animals were deeply anesthetized with pentobarbital under ketamine anesthesia, and then, whole blood was collected from left ventricle.

Animal Experiments

We examined SIV infections in a group of Burmese rhesus macaques (n = 10) sharing the MHC-I haplotype 90-010-Id (D). The determination of MHC-I haplotypes was based on the family study in combination with the reference strand-mediated conformation analysis (RSCA) of Mamu-A and Mamu-B genes and detection of major Mamu-A and Mamu-B alleles by cloning the reverse transcription (RT)-PCR products as described previously [21,34,37]. Macaques R01-012 and R01-009 used in our previous report [35] and macaques R03-021 and R03-016 used in an unpublished experiment were included in the present study. Five macaques R01-009, R06-020, R06-033, R03-021, and R03-016 received a prophylactic DNA prime/SeV-Gag boost vaccine (referred to as DNA/SeV-Gag vaccine) [35]. The DNA used for the vaccination, CMV-SHIVdEN, was constructed from an nef-deleted and nef-deleted simian–human immunodeficiency virus SHIVMD14YE [30] molecular clone DNA (SIVGP1) and has the genes encoding SIVmac239 Gag, Pol, Vif, and Vpx, and HIV Tat and Rev. At the DNA vaccination, animals received 500 mg of CMV-SHIVdEN DNA intramuscularly. Six weeks after the DNA prime, animals received a single boost intranasally with 6x10^9 cell infectious units (CIUs) of F-deleted replication-defective SeV-Gag [39,40]. All animals were challenged intravenously with 1,000 TCID50 (50 percent tissue culture infective doses) of SIVmac239 [41]. At week 1 after SIV challenge, macaque R03-021 was inoculated with nonspecific immunoglobulin G (IgG) and macaques R03-016 with IgG purified from neutralizing antibody-positive plasma of chronically SIV-infected macaques in our previous experiment [42].

Analysis of SIV Antigen-specific CD8+ T-cell Responses

SIV antigen-specific CD8+ T-cell responses were measured by flow-cytometric analysis of gamma interferon (IFN-γ) induction as described previously [43]. Autologous herpesvirus papio-immortalized B-lymphoblastoid cell lines (B-LCLs) were established from peripheral blood mononuclear cells (PBMCs) which were obtained from individual macaques before SIV challenge [44]. PBMCs obtained from SIV-infected macaques were cocultured with autologous B-LCLs pulsed with peptides or peptide pools using panels of overlapping peptides spanning the entire SIVmac239 Gag, Pol, Vif, Vpx, Tat, Rev, Env, and Nef amino acid sequences. Alternatively, PBMCs were cocultured with B-LCLs infected with a vaccinia virus vector expressing SIVmac239 Gag for Gag-specific stimulation. Intracellular IFN-γ staining was performed using Cytofix/Cytoperm kit (BD, Tokyo, Japan). Fluorescein isothiocyanate-conjugated anti-human CD4 (BD), Peridinin chlorophyll protein (PerCP)-conjugated anti-human CD8 (BD), allophycocyanin Cy7 (APC-Cy7)-conjugated anti-human CD3 (BD), and phycoerythrin (PE)-conjugated anti-human IFN-γ antibodies (Biolegend, San Diego, CA) were used. Specific T-cell levels were calculated by subtracting non-specific IFN-γ+ T-cell frequencies from those after peptide-specific stimulation. Specific T-cell levels less than 100 cells per million PBMCs were considered negative.

Sequencing Analysis of Plasma Viral Genomes

Viral RNAs were extracted using High Pure Viral RNA kit (Roche Diagnostics, Tokyo, Japan) from macaque plasma samples. Fragments of cDNAs encoding SIVmac239 Gag and Nef were amplified by nested RT-PCR from plasma RNAs and subjected to direct sequencing by using dye terminator chemistry and an automated DNA sequencer (Applied Biosystems, Tokyo, Japan) as described before [45]. Predominant non-synonymous mutations were determined.

Statistical Analysis

Statistical analysis was performed using Prism software version 4.03 with significance levels set at a P value of <0.050 (GraphPad Software, Inc., San Diego, CA). Plasma viral loads were log transformed and compared by an unpaired two-tailed t test.
Results

Lower Viral Loads in D+ Macaques in the Chronic Phase of SIV Infection

We first investigated SIVmac239 infection of five unvaccinated Burmese rhesus macaques sharing the MHC-I haplotype D+ (referred to as D+ macaques). Confirmed MHC-I alleles consisting of this haplotype is Mamu-A1*032:02, Mamu-B*004:01, and Mamu-B*102:01:01. These animals showed lower set-point plasma viral loads (Fig. 1). Comparison of plasma viral loads between these five animals and our previous cohorts of SIVmac239-infected Burmese D-negative (D−) rhesus macaques (n = 20) [21] revealed no
Figure 4. SIV Nef-specific CD8+ T-cell responses in macaques R05-006, R06-034, and R-360. Nef35–49-specific (upper panels) and Nef115–129-specific (lower panels) CD8+ T-cell responses were examined at indicated time points after SIVmac239 challenge. doi:10.1371/journal.pone.0054300.g004

Figure 5. Plasma viral loads after SIVmac239 challenge in vaccinated D+ macaques. (A) Changes in plasma viral loads after challenge vaccinated macaques possessing MHC-I haplotype D. (B) Comparison of plasma viral loads at 3 months (left panel) and 6 months (right panel) between five unvaccinated D+ and five vaccinated D+ animals. Viral loads at 3 months in vaccinated animals were significantly lower than those in the unvaccinated (p = 0.0149 by t-test). doi:10.1371/journal.pone.0054300.g005
significant difference at 3 months after SIV challenge \((p = 0.2436\) by t-test\), but viral loads in the former D\(^+\) animals became significantly lower than the latter after 6 months \((p = 0.0360\) at 6 months and \(p = 0.0135\) at 9 months by t-test; Fig. 1). Four of these five macaques sharing MHC-I haplotype D showed low viral loads, less than \(5 \times 10^3\) copies/ml, after 6 months, whereas macaque R01-012 maintained relatively higher viral loads.

**Predominant Nef-specific CD8\(^+\) T-cell Responses**

We examined SIV antigen-specific CD8\(^+\) T-cell responses by detection of antigen-specific IFN-\(\gamma\) induction. In the very acute phase, we did not have enough PBMC samples for measurement of individual SIV antigen-specific CD8\(^+\) T-cell responses and focused on examining Gag-specific CD8\(^+\) T-cell responses in most animals. At week 2 after challenge, Gag-specific CD8\(^+\) T-cell responses were undetectable in four of five animals (Fig. 2).
We then examined CD8+ T-cell responses specific for individual SIV antigens in the early and the late phases (Fig. 3). Nef-specific but not Gag-specific CD8+ T-cell responses were predominant in most D+ animals. Gag-specific CD8+ T-cell responses were dominantly induced in macaque R08-005 showing very low set-point viral loads. Macaque R01-012 having higher viral loads showed poor CD8+ T-cell responses in the early phase.

Among four D+ animals controlling SIV replication with less than 5 x 10^4 copies/ml of plasma viral loads after 6 months, Gag-specific CD8+ T-cell responses were dominant only in macaque R08-005, while efficient Nef-specific CD8+ T-cell responses were induced in the remaining three, suggesting possible contribution of Nef-specific CD8+ T-cell responses to SIV control in these three controllers (R05-006, R06-034, and R-360). We then attempted to localize Nef CD8+ T-cell epitopes shared in these animals and found Nef 35–49-specific and Nef 115–129-specific CD8+ T-cell responses (Fig. 4), although we did not have enough samples for mapping the exact epitopes.

**Reduction of Viral Loads in the Early Phase of SIV Infection by Prophylactic Vaccination**

We also investigated SIVmac239 infection of additional five, vaccinated Burmese rhesus macaques sharing the MHC-I haplotype D. These animals received a prophylactic DNA/SeV-Gag vaccination. In four of these five vaccinated macaques, plasma viremia became undetectable after 6 months, Gag-specific CD8+ T-cell responses were predominant in only in macaque R08-005, while efficient Nef-specific CD8+ T-cell responses were induced in the remaining three, suggesting possible contribution of Nef-specific CD8+ T-cell responses to SIV control in these three controllers (R05-006, R06-034, and R-360). We then attempted to localize Nef CD8+ T-cell epitopes shared in these animals and found Nef 35–49-specific and Nef 115–129-specific CD8+ T-cell responses (Fig. 4), although we did not have enough samples for mapping the exact epitopes.

**Selection of Mutations in Nef CD8+ T-cell Epitope-coding Regions**

To see the effect of selective pressure by Nef-specific CD8+ T-cell responses on viral genome mutations, we next analyzed nucleotide sequences in viral nef cDNAs amplified from plasma RNAs obtained at several time points after SIV challenge. Nonsynonymous mutations detected predominantly in Nef 35–49-coding and Nef 115–129-coding regions were as shown in Fig. 9. Remarkably, all the unvaccinated and vaccinated D+ animals showed rapid selection of mutations in the Nef 35–49-coding region in the early phase. In contrast, vaccinated animal R06-033 that failed to control viremia showed higher Nef 115–129-specific CD8+ T-cell responses in the early phase than those in the chronic phase.
unvaccinated animals eliciting Nef115–129-specific CD8+ T-cell responses. These mutations were also detected in two of three vaccinated animals eliciting Nef115–129-specific CD8+ T-cell responses. We also analyzed viral gag sequences to see the effect of Gag-specific CD8+ T-cell pressure on viral genome mutations in vaccinated animals (data not shown). Our previous study [35] showed rapid selection of a mutation leading to a glutamine (Q) to lysine (K) change at the 58th residue in Gag (Q58K) at week 5 in vaccinated macaque R01-009, although no more samples were available for this sequencing analysis. This Q58K mutation results in escape from Gag50–65-specific CD8+ T-cell recognition. In the present study, macaque R03-016 showed rapid selection of a mutation leading to a K-to-asparagine (N) change at the 478th residue in Gag in 1 month. These results may reflect rapid disappearance of detectable plasma viremia in 1 or 2 months in these two vaccinees. Macaque R06-020 showed selection of a gag mutation in 3 months, while other two vaccinees (R06-033 and R03-021) selected no gag mutation in the early phase.

**Discussion**

HIV infection in humans with polymorphic MHC-I genotypes induces various patterns of viral antigen-specific CD8+ T-cell responses. Previous studies have found several protective MHC-I alleles associated with lower viral loads and slower disease progression in HIV/SIV infection [7,13,14,16,17]. Elucidation of the mechanisms of viral control associated with individual protective MHC-I alleles would contribute to HIV cure and vaccine-based prevention. Because CD8+ T-cell responses specific for some MHC-I-restricted epitopes can be affected by those specific for other MHC-I-restricted epitopes due to immunodominance [29,46,47], macaque groups sharing MHC-I genotypes at the haplotype level are useful for the analysis of cooperation of multiple epitope-specific CD8+ T-cell responses. Previously, we reported a group of Burmese rhesus macaques sharing MHC-I haplotype 90-120-Ia(A), which dominantly induce Gag-specific CD8+ T-cell responses and tend to show slower disease progression after SIVmac239 challenge [21]. In the present study, we presented another type of protective MHC-I haplotype, which is not associated with dominant Gag-specific CD8+ T-cell responses. Significant reduction of viral loads in unvaccinated macaques possessing this D haplotype compared to those in D2 macaques was observed after 6 months. Analysis of SIV infection in macaques sharing this protective MHC-I haplotype would lead to understanding of CD8+ T-cell cooperation for viral control.
Involvement of Non-Gag-Specific CTL in SIV Control

Sequencing analysis of viral genomes showed rapid selection of mutations in the Nef36-44 coding region within 3 months in all the D* animals. This is consistent with our results that Nef35-49-specific CD8 T-cell responses were mostly induced in the early phase but undetectable in the chronic phase. These mutations were not consistently selected in our previous D* cohorts and thus considered as MHC-I haplotype D-associated mutations. This suggests strong selective pressure by Nef35-49-specific CD8+ T-cell responses in the acute phase of SIVmac239 infection in D* macaques, although it remains undetermined whether these mutations result in viral escape from Nef35-49-specific CD8+ T-cell recognition.

Nef15-129-specific CD8+ T-cell responses were detected in six D* animals. In five of them, nonsynonymous mutations in the Nef19-129 coding region were observed in the chronic phase. At least, we confirmed viral escape from Nef115-129-specific CD8+ T-cell recognition by a mutation leading to a K-to-arginine (R) (K126R) substitution at Nef residue 126 (Fig. 10). The number of nonsynonymous substitutions per the number of sites estimated to be nonsynonymous (dN) exceeded that estimated to be synonymous (dS) during the evolution process of Nef115-129 coding region, but the value did not show statistically significant difference from that of neutral selection. Among three unvaccinated animals that controlled SIV replication without dominant Gag-specific CD8+ T-cell responses, amino acid substitutions in the Nef19-129 coding region were observed in a year in macaques R06-034 and R-360 but after 2 years in macaque R05-006. The former two animals tended to show earlier increases in plasma viral loads in the chronic phase, while the latter R05-006 maintained higher frequencies of Nef115-129-specific CD8+ T-cell responses. Nef15-129-specific CD8+ T-cell responses were efficient in the chronic phase in vaccinated controllers R03-021 and R03-016 but decreased in R06-033 that failed to contain SIV replication. Although a possible effect of this haplotype-associated factors other than CD8+ T-cell responses such as NK activity on SIV infection [48, 49, 50] remains undetermined, these results imply involvement of Nef-specific CD8+ T-cell responses in the SIV control associated with MHC-I haplotype D.

Unvaccinated macaque R08-005 dominantly elicited Gag antigen-specific CD8+ T-cell responses and showed rapid selection of a mutation encoding Gag 257 residue, which was not observed in any other D* animals. Nef-specific CD6+ T-cell responses were detectable only at week 2 in the acute phase (data not shown) but a mutation in the Nef42 coding region was rapidly selected. It is speculated that those dominant Gag-specific CD8+ T-cell responses associated with the second, non-D MHC-I haplotype were effective in this animal. Nef35-49-specific CD8+ T-cell responses may not be efficient due to immunodominance but exert some suppressive pressure on viral replication. DNA/SeV-Gag vaccination resulted in earlier reduction of viral loads after SIV challenge. Vaccines showed significantly lower viral loads at 3 months than those in unvaccinated animals. Gag-specific CD8+ T-cell responses were elicited at week 2 in all the vaccines but not in the unvaccinated except for one animal R00-003. No gag mutations were shared in the vaccines in the acute phase, but three of them showed rapid selection of individual nonsynonymous mutations in gag. Rapid selection of mutations in the Nef36-44 coding region was consistently detected even in these vaccines. These results suggest broader CD8+ T-cell responses consisting of dominant vaccine antigen Gag-specific and inefficient naive-derived Nef-specific ones in the acute phase. In three vaccinated animals, Gag-specific CD8+ T-cell responses became lower or undetectable, and instead, Nef-specific CD8+ T-cell responses became predominant in the chronic phase.

In summary, we found a protective MHC-I haplotype not associated with dominant Gag-specific CD8+ T-cell responses in SIVmac239 infection. Our results in D* macaques suggest suppressive pressure by Nef35-49-specific and Nef115-129-specific CD8+ T-cell responses on SIV replication, contributing to reduction in set-point viral loads. DNA/SeV-Gag-vaccinated D* animals induced Gag-specific CD8+ T-cell responses in addition to Nef-specific ones after SIV challenge, resulting in earlier containment of SIV replication. This study presents a pattern of SIV control with involvement of non-Gag antigen-specific CD8+ T-cell responses, contributing to accumulation of our knowledge on HIV/SIV control mechanisms.
