Scalable distributed gate-model quantum computers

Laszlo Gyongyosi1,2,3 & Sandor Imre1

A scalable model for a distributed quantum computation is a challenging problem due to the complexity of the problem space provided by the diversity of possible quantum systems, from small-scale quantum devices to large-scale quantum computers. Here, we define a model of scalable distributed gate-model quantum computation in near-term quantum systems of the NISQ (noisy intermediate scale quantum) technology era. We prove that the proposed architecture can maximize an objective function of a computational problem in a distributed manner. We study the impacts of decoherence on distributed objective function evaluation.

As the development of quantum computers evolve extensively1–29, the power of quantum computations has become more interpretable for efficient problem-solving. However, while experimental quantum computers are currently under development, smaller quantum devices and quantum terminals are currently available in practice. As an adequate answer to the quantum supremacy of quantum computers, the development of the quantum Internet30–43 has already started both in theory and experiment32,34,36,44–46, with a primary aim to provide unconditional security with advanced network services31–34,36,41,44–64. A common attribute of quantum computer architectures and the quantum Internet30,31,52,65–119, from an abstract theoretical point of view, are scalable distributed quantum systems120–137. Performing quantum computation in a distributed quantum system can also be approached as a maximization problem since a computational problem fed into the quantum system defines an objective function. The optimization of a distributed problem solving is therefore equivalent to a maximization of the objective function of a computational problem fed into the distributed quantum system (Objective function examples can be found in5,8,9.). A primary aim of these distributed quantum systems is therefore the maximization of an objective function in a distributed manner, via quantum CPUs in a quantum computer1–4,14,138–141, or by quantum terminals39,40,45,64,125,126,128,131,133 in a quantum Internet setting.

The problem of scalable quantum computation in a distributed quantum system is a challenge because of the complexity of the problem space provided by the diversity of possible quantum systems. The distributed quantum computational model has to include arbitrarily scaled quantum systems, from smaller quantum devices to large-scale quantum computers and the quantum Internet. As a corollary, the definition and parameterization of a scalable model for a distributed gate-model quantum computation is a hard problem, and no general solution is currently available.

Here, we study the problem of scalable quantum processing in distributed near-term quantum systems. We define a scalable distributed model of gate-model quantum computation and conceive the scaling attributes and unitaries of a distributed quantum information processing for problem-solving. The proposed scalable distributed quantum network integrates distributed quantum processing in arbitrarily scaled quantum systems.

In our context, an arbitrarily scaled quantum system can identify small, medium, or large-scale distributed quantum systems. The system model consists of an arbitrary number of quantum nodes connected by different levels of entangled connections (level of entanglement refers to the number of spanned nodes between a source and target node). The quantum system can refer to a quantum device, a quantum computer, or an arbitrary quantum Internet setting in which several quantum computers (quantum nodes) share entanglement to perform distributed quantum computations. The quantum nodes have to achieve the objective function maximization in a distributed way such that each node is allowed to apply local unitaries and connected via an arbitrary level of entanglement. In a small-scale system, the quantum nodes are connected by one-level entanglement while for a medium- or large-scale system, the level of entanglement between quantum nodes can be arbitrarily large. The local unitaries of the nodes are defined in a way that allows the distributed quantum system to implement a gate-model quantum computation in a distributed way.

We characterize a system model of a scalable distributed quantum system that allows for the performance of distributed gate-model quantum computation in a scalable manner. We define the scalable attributes of the system model and the gate parameters of the local unitaries of the quantum nodes for the objective function maximization. Our approach allows for the optimization of a computational problem fed into a distributed quantum system in a scalable manner.
maximization, assuming that multipartite entanglement is utilized in the local nodes, and evaluate a cost function. The system model also assumes that the distributed quantum network evolves with time; thus, we utilize the impacts of decoherence in the distributed objective function evaluation and maximization.

Since the proposed system model is parameterizable for different physical systems, the results are applicable for distributed quantum computations in quantum computers, quantum devices, quantum networking, and the quantum Internet. Derivations focus on near-term quantum systems such as qubit-based implementations, qubit-based quantum computer architectures, and entangled network structures connected by multipartite qubit entanglement; however, the results are extendable for arbitrary dimensional quantum systems.

The novel contributions of our manuscript are as follows:

- We define a distributed quantum system to implement a scalable distributed gate-model quantum computation.
- We conceive the unitary operations of the distributed system and prove that the distributed quantum system can maximize the objective function of an arbitrary computational problem.
- We reveal the impacts of decoherence on the distributed objective function evaluation and define a suitable cost function for scalable distributed quantum computation.

This paper is organized as follows. In Sect. 2, the problem statement and system model are given. Section 3 defines the distributed quantum computational model. In Sect. 4, the scaling methods are concealed. Finally, Sect. 5 concludes the results. Supplemental information is included in the Appendix.

**Scalable distributed quantum system**

**Problem statement.** The issues that need to be addressed are given in Problems 1–4.

**Problem 1** Define the scaling attributes of an arbitrary distributed quantum system to resolve an arbitrary computational problem in a distributed manner.

**Problem 2** Define the unitary operations of the distributed system that allows for the implementation of a distributed gate-model quantum computation.

**Problem 3** Prove that the distributed quantum system can maximize the objective function of an arbitrary computational problem fed into the distributed quantum system.

**Problem 4** Determine the impacts of decoherence on the distributed objective function evaluation, and define a suitable cost function for the distributed quantum computation.

The resolutions to Problems 1–4 are proposed in the Theorems and Lemmas of the manuscript.

**System model.** The system model of the $N$ scalable distributed physical system is as follows. In $N = (V, S)$, the $|V|$ quantum nodes are connected via $|S|$, $l$-level entangled connections (An entangled connection between the quantum nodes refers to a shared multipartite entanglement. Between two nodes, $x$ and $y$, the entangled connection identifies a bipartite quantum entanglement. For a qubit setting, the $d = 2$ dimensional two-partite maximally entangled states are the so-called Bell states; here one can assume the use of the $|\beta_{00}\rangle$ state, $|\beta_{00}\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$ in the system model.), where $V$ is a set of quantum nodes and $S$ is a set of entangled connections. For an $l$-level entangled connection, the $d(x,y)_{l}$ hop distance in $N$ is

$$d(x,y)_{l} = 2^{l-1},$$  \hspace{1cm} (1)

with $d(x,y)_{l} = 1$ intermediate nodes (The level $l$ of an entangled connection assumes that each entanglement level doubles the hop-distance between $x$ and $y$, which is a general model in quantum networking. It is also used in the so-called doubling architecture of entanglement distribution, in which the entanglement levels are increased via entanglement swapping\textsuperscript{39,41}. Note, that $l$ can model any hop-distance between the nodes.) between the nodes $x$ and $y$. Thus, $l = 1$ refers to a direct connection between two quantum nodes $x$ and $y$ without intermediate quantum nodes in the distributed system $N$.

**Proposition 1** (Distributed quantum system for a scalable distributed gate-model quantum computation). An arbitrary distributed quantum system $N$ is scalable via the entanglement level of entangled connections, by the gate parameters of the local unitaries of the quantum nodes, and by local measurements in the nodes. The $N$ distributed quantum system can implement a scalable gate-model quantum computation in a distributed manner.

**Proof** The level $l$ of the entangled connections between the nodes depends on the physical size and topology of $N$. Without loss of generality, for an $s$ small-scale distributed quantum system (quantum device, quantum terminal, smaller quantum computer),
\[ I = 1, \quad (2) \]

while for an \( m \) medium, or \( l \) large-scale distributed quantum system (medium or large-scale quantum computer, quantum repeater network, arbitrary quantum communication network, quantum internet),

\[ I \geq 1. \quad (3) \]

A \( \mathcal{P}(A \rightarrow B) \) computational path of \( N \) is modeled as a set \( V = \{ V_1, \ldots, V_l \} \) of \( L \) quantum nodes, with a set \( S = \{ E_1, \ldots, E_{l-1} \} \) of \( L - 1 \) entangled connections between the nodes, where \( E_j \) identifies an entangled connection between \( d \)-dimensional quantum states \( j \) and \( k \) in nodes \( V_j \) and \( V_k \). Focusing on near-term distributed quantum systems, we use \( d = 2 \); thus, \( j \) and \( k \) refer to qubits throughout the manuscript. The aim of the \( \mathcal{P}(A \rightarrow B) \) computational path is to maximize a particular objective function \( C_{\mathcal{P}(A \rightarrow B)} \) of an arbitrary computational problem in a distributed manner using the nodes and entangled connections of the path.

The allowed operations for a node pair \( V_{xy} = \{ V_x, V_y \} \) with a shared \( l \)-level entangled connection \( E_j, j = 1, \ldots, L - 1 \) are defined as follows.

A scalable gate-model quantum computation can be set up in \( N \) by allowing the local nodes to perform local unitaries using the Pauli \( \sigma_x \) and \( \sigma_z \) operators. The local unitaries scaled by the gate parameters, in the following manner.

A node pair \( \{ V_{x}, V_{y} \} \) is allowed perform a local single-qubit unitaries\(^\text{12,14} \)

\[ U(X_j, \beta_j) = \exp \left( -i \beta_j X_j \right) \quad (4) \]

where \( \beta_j \in [0, \pi] \) is the gate parameter of the unitary, while \( X \) is the Pauli \( \sigma_x \) operator, and

\[ U(X_k, \beta_k) = \exp \left( -i \beta_k X_k \right) \quad (5) \]

on qubits \( j \) and \( k \) in nodes \( V_x \) and \( V_y, \beta_k \in [0, \pi] \).

The node pair is also allowed to realize a distributed unitary

\[ U(Z_j Z_k, \gamma_{jk}) = U(Z_j Z_k, \gamma_j) U(Z_j Z_k, \gamma_k) = \exp \left( -i (\gamma_j) Z_j Z_k \right) \exp \left( -i (\gamma_k) Z_j Z_k \right) \quad (6) \]

on qubits \( j \) and \( k \) using the \( l \)-level entangled connection \( E_j = \langle jk \rangle \), where \( \gamma_{jk} \in [0, 2 \pi] \) is the gate parameter of the distributed unitary\(^\text{12,14} \), defined as

\[ \gamma_{jk} = \gamma_j + \gamma_k. \quad (7) \]

where \( \gamma_j, \gamma_k \in [0, \pi] \) are the local gate parameters applied on qubits \( j \) and \( k, Z \) is the Pauli \( \sigma_z \) operator, while

\[ U(Z_j Z_k, \gamma_{jk}) = U(Z_j Z_k, \gamma_j) U(Z_j Z_k, \gamma_k) \]

\[ = \exp \left( -i (\gamma_j) Z_j Z_k \right) \exp \left( -i (\gamma_k) Z_j Z_k \right) \]

\[ = (\cos (\gamma_j) I - i \sin (\gamma_j) Z_j Z_k) (\cos (\gamma_k) I - i \sin (\gamma_k) Z_j Z_k) \]

\[ = \frac{1}{2} \left( \cos (\gamma_j) \cos (\gamma_k) I - i \cos (\gamma_j) \sin (\gamma_k) Z_j Z_k - i \cos (\gamma_k) \sin (\gamma_j) Z_j Z_k \right) \]

\[ + \frac{1}{2} \left( 1 \sin (\gamma_j + \gamma_k) I - i \left( \frac{1}{2} \sin (\gamma_j + \gamma_k) - \sin (\gamma_j - \gamma_k) \right) Z_j Z_k \right) \]

\[ = \cos (\gamma_j + \gamma_k) I - 2i \left( \frac{1}{2} \sin (\gamma_j + \gamma_k) - \sin (\gamma_j - \gamma_k) \right) Z_j Z_k. \quad (8) \]

Thus, setting

\[ \gamma_j = \gamma_k = \frac{1}{2} \gamma_{jk} \quad (9) \]

the result in (8) can be evaluated as

\[ U(Z_j Z_k, \gamma_{jk}) = U(Z_j Z_k, \gamma_j) U(Z_j Z_k, \gamma_k) \]

\[ = \cos (\gamma_j) I - i \sin (\gamma_j) Z_j Z_k \]

\[ = \exp \left( -i (\gamma_j) Z_j Z_k \right) \quad (10) \]

A node \( V_k \) can also apply an \( U^C_k \) local coupling unitary to connect qubits \( i \) and \( j \) from entangled connections \((i - 1)\langle ii \rangle \) and \((jk)\rangle \) in \( V_k \), as

\[ U^C_k = \exp \left( -i H^{(ij)} \right) \quad (11) \]

where \( H^{(ij)} \) is a Hamiltonian, and also in \( V_j \) on the qubits \( k \) and \( k + 1 \) of entangled connections \((jk)\rangle \) and \((k + 1)\langle kk + 1 \rangle \), as

\[ U^C_j = \exp \left( -i H^{(kk+1)} \right) \quad (12) \]
where $H^{(k,k+1)}$ is a Hamiltonian, to connect qubits $k$ and $k + 1$, and remote entangled connections.

Therefore, the $U_{xy}$ unitary associated to a given node pair $\{V_x, V_y\}$ connected by an $l$-level entanglement $E_l$ in the distributed quantum system $N$ is defined as

$$U_{xy} = U_x U_y = U(B_j, \beta_j) U(Z_j Z_k, \gamma_j) U(B_k, \beta_k) U(Z_j Z_k, \gamma_k)$$

$$= U(X_j, \beta_j) U(X_k, \beta_k) U(Z_j Z_k, \gamma_j) U(Z_k, \gamma_k)$$

$$= \exp \left( -i \beta_j X_j \right) \exp \left( -i \beta_k X_k \right) \exp \left( -i \gamma_j Z_j Z_k \right) \exp \left( -i H^{(1)} \right) \exp \left( -i H^{(k,k+1)} \right),$$

where $U_x$ is the unitary of a node $V_x$, $x = 1, \ldots, L$, defined as

$$U_x = U(X_j, \beta_j) U(Z_j Z_k, \gamma_j),$$

while $U_y$ is the unitary of its neighbor node $V_y$, as

$$U_y = U(X_k, \beta_k) U(Z_j Z_k, \gamma_k).$$

Since unitaries (14) and (15) allows us to realize a gate-model quantum computation, it follows that the $\{V_x, V_y\}$ node pairs of the distributed quantum system $N$ can implement quantum computation using their entangled connections in a distributed manner.

**Methods.** Proposition 2 To model multipartite entanglement in a particular node $V_x$, qubit $j$ has entangled connection with $k$ to formulate $\langle jk \rangle$, and also with $\Gamma_j$ remote qubits, $n_1, \ldots, n_{\Gamma_j}$, which are not neighbors of qubit $k$ (These $\Gamma_j$ qubits have no connections with qubit $k$). The total number of qubits that are neighbor of $j$ but not neighbor of $k$ is $\Gamma_j + 1$.

**Proof** Each entangled connection $E_l$ has a contribution $\xi_{E_l}$ to an $F_{P(A \rightarrow B)}$ target function of a computational path $P(A \rightarrow B)$ (will be proven in Sect. 3)

$$F_{P(A \rightarrow B)} = \max_{\psi^*} \langle \psi^* | C_{P(A \rightarrow B)} | \psi^* \rangle$$

$$= \frac{1}{2} \sum_{j=1}^{L-1} \xi_{E_j},$$

where $|\psi^*\rangle$ is the output state of $P(A \rightarrow B)$, defined as

$$|\psi^*\rangle = U_{P(A \rightarrow B)} |+\rangle,$$

where $|+\rangle = \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle)$, while $U_{P(A \rightarrow B)}$ is defined as a unitary sequence associated to $P(A \rightarrow B)$, as

$$U_{P(A \rightarrow B)} = U_L U_{L-1} \cdots U_1$$

$$= U(X_L, \beta_L) U(X_{L-1}, \beta_{L-1}) U(Z_{L-1} Z_L, \gamma_{L-1, L}) U(Z_L, \gamma_L)$$

$$\cdots U(X_2, \beta_2) U(X_1, \beta_1) U(Z_1, \gamma_1)$$

$$= \prod_{j \in P(A \rightarrow B)} U(X_j, \beta_j) \prod_{\langle jk \rangle \in P(A \rightarrow B)} U(Z_j Z_k, \gamma_{jk}),$$

where $\langle jk \rangle \in P(A \rightarrow B)$ refers to an $E_l$ entangled connection between qubits $j$ and $k$ on the computational path $P(A \rightarrow B)$.

The $n$-qubit length input system $|\ell\rangle$ of the distributed system $N$, is defined as a product of $\sigma$ eigenstates, as

$$|\ell\rangle = |+\rangle^2 \cdots |+\rangle_n = |+\rangle^\otimes n = \frac{1}{\sqrt{2^n}} \sum_z |z\rangle,$$

where $|z\rangle$ is a computational basis state, $z$ is an $n$-length string,

$$z = z_1 z_2 \cdots z_n,$$

where $z_i$ identifies an $i$-th bit, $z_i \in \{-1, 1\}$, and $|+\rangle_i$ is the input system of an $i$-th computational path (As $N$ is a quantum computer system or a quantum device with quantum registers, then $|\ell\rangle$ refers to a quantum register in the superposition of $n$ qubits, while a given node $A_i$ identifies the $i$-th source qubit, $|+\rangle_i$, of the $n$-length quantum register. In the current system model, the input system fed into the distributed system can also refer to a quantum register, physically not distributed between distant parties.) $P(A_i \rightarrow B_i)$.

The nodes of the distributed system also can perform $M[\ell_{mk}]$ local measurements in a base $\ell_{mk} \in \{\ell_{m0}, \ell_{m1}\}$ (see (35), (36)) to realize an $L_U$ upload method and an $L_D$ download procedure. The $L_U$ upload procedure is an information delocalization method, in which a source system is uploaded by a source node onto the network state formulated by the entangled connections of the intermediate nodes of the distributed system. The $L_D$ download procedure is an information localization procedure, in which the uploaded and transformed information (transformed by the local unitaries of the quantum nodes in our setting) is localized into a particular target node from the network state of intermediate nodes. Since the distributed quantum system evolves with
Proposition 3 In a source node $A_i$, the $L_U(|\Phi\rangle_i)$ uploading is realized by a $\mathcal{M}_B$ Bell measurement$^{26}$ applied on input system $|\Phi\rangle_i$ and the first particle of chain $|\Phi\rangle_i$, that identifies the $|\Phi\rangle_i$ network state of computational path $\mathcal{P}(A_i \rightarrow B_i)$.

Proof The $|\Phi\rangle_i$ network state is defined as

$$|\Phi\rangle_i = U(\hat{\theta}_i) \frac{1}{\sqrt{2}} \left( |0\rangle_{\text{aux}} |0\rangle_2^{2(L-1)} + |1\rangle_{\text{aux}} |1\rangle_2^{2(L-1)} \right),$$

(21)

where sub-index 1 identifies the first particle of $|\Phi\rangle_i$ of $\mathcal{P}(A_i \rightarrow B_i)$ maximally entangled with the remaining $2(L-1)$ qubits of the chain of $\mathcal{P}(A_i \rightarrow B_i)$.

The $L_U(|\Phi\rangle_i)$ uploading process results in

$$L_U(\alpha_i |0\rangle + \beta_i |1\rangle) = U(\hat{\theta}_i) \left( \alpha_i |0\rangle_2^{2(L-1)} + \beta_i |1\rangle_2^{2(L-1)} \right)$$

$$= U(\hat{\theta}_i) \frac{1}{\sqrt{2}} \left( |0\rangle_2^{2(L-1)} + |1\rangle_2^{2(L-1)} \right),$$

(22)

where $\alpha_i |0\rangle + \beta_i |1\rangle = \frac{1}{\sqrt{2}} (|0\rangle + |1\rangle)$. Applying $L_U(|\Phi\rangle_i)$ for $i = 1, \ldots, n$, uploads the input system $|s\rangle$ in a distributed manner, as

$$L_U(|s\rangle) = L_U(|\Phi\rangle_i |s\rangle),$$

(23)

to the $|\Phi\rangle^n$ distributed network state formulated via $n$ computational paths $\mathcal{P}(A_1 \rightarrow B_1), \ldots, \mathcal{P}(A_n \rightarrow B_n)$, as

$$|\Phi\rangle^n = U(N) \frac{1}{\sqrt{2}} \left( (|00\rangle_1^{n} |0\rangle_2^{n(L-1)} + |11\rangle_1^{n} |1\rangle_2^{n(L-1)} \right)$$

$$= U(N) \frac{1}{\sqrt{2}} \left( |0\rangle_1^n |0\rangle_2^{n(L-1)} + |1\rangle_1^n |1\rangle_2^{n(L-1)} \right),$$

(24)

while indices $1, \ldots, n$ identify the auxiliary systems used for the uploading procedure in the $n$ source nodes$^{26,142}$, while $U(N)$ the unitary of $N$ is defined as,

$$U(N) = \prod_{j \in N} U(X_j, \beta_j) \prod_{(k) \in N} U(Z_k, \gamma_k) = U\left( \vec{i}_1 \right) \cdots U\left( \vec{i}_1 \right),$$

where $U(\vec{i}_1)$ refer to the unitary associated to an $i$-th path $\mathcal{P}(A_i \rightarrow B_i), i = 1, \ldots, n$, defined as a unitary sequence of $L$ unitaries,

$$U\left( \vec{i}_1 \right) = U_{i,1} U_{i,1-L} \cdots U_{i,1},$$

(25)

where $U_{i,1}$ identifies the unitary of a given node $V_x$ of $\mathcal{P}(A_i \rightarrow B_i)$, as

$$U_{i,1} = U(\beta_{i,1}, X_{i,1}) U(\gamma_{i,1}, Z_{i,1}),$$

(26)

and $U(\vec{i}_1)$ is a unitary sequence of $2L$ unitaries implemented via $L$ nodes $V_x, x = 1, \ldots, L$, in $\mathcal{P}(A_i \rightarrow B_i)$.

The $L_U(|s\rangle)$ operation therefore results in

$$L_U(|s\rangle) = U(N) \frac{1}{\sqrt{2}} \left( |0\rangle_1^n |0\rangle_2^{n(L-1)} + |1\rangle_1^n |1\rangle_2^{n(L-1)} \right),$$

(27)

that yields the output system of $N$

$$|\phi^+\rangle = U(N)|s\rangle$$

(28)

distributed between the $n$ receiver nodes $B_1, \ldots, B_n$. Thus, the outputs of the $n$ paths, $U(N)|s\rangle$ can be localized onto the $n$ receivers in the downloading procedure$^{6,143}$.

To verify (22) and (27), we recall the formalisms of $^{44,145}$ . The input system $|+\rangle_i$ of a given node $A_i$ can be rewritten as

$$|+\rangle_i = \tilde{i}_0 |0\rangle + \tilde{i}_1 |1\rangle,$$

(29)

and let $|\Phi_i\rangle$ be as given in (21), then

$$|\Phi_i\rangle|+\rangle_i = \sum_{k=0,1} \tilde{i}_k U(\vec{i}_1) \frac{1}{\sqrt{2}} \left( (M|m_k\rangle L)_2^{2(L-1)} \right) |m_k\rangle |k\rangle_0,$$

(30)

where indices 0 and 1 identify the input system $|+\rangle_i$ and the first qubit of the first EPR pair of chain $|\Phi_i\rangle$ that serves as an $|\text{aux}\rangle$ auxiliary qubit system, $\mathcal{H}_{\text{aux}} = \mathbb{C}^2$, maximally entangled with the $2(L-1)$-qubit length system.
formulating orthogonal states as $\langle L \rangle_{2}^{2(L-1)} = \{ |0\rangle_{2}^{2(L-1)}, |1\rangle_{2}^{2(L-1)} \}$, while $|m_j\rangle$ is an orthogonal basis.\(^{76,144,145}\)

Then, in node $A_i$, an MB Bell measurement is applied on subsystems 0 and 1, that yields a projection onto $\mathcal{M}_B(A_i) : |B_i\rangle_{10} = \sum_j |m_j\rangle_1 |j\rangle_0$, (31)

while the $|\Phi'\rangle_i$, post-measurement network state is evaluated as

$$
|\Phi'\rangle_{1} = \sum_{j} U(\tilde{\theta}_j) \left( \hat{\iota}_j M [m_j] (|L\rangle_{n+1}^{2L-1}) \right) = U(\tilde{\theta}_j) \left( \hat{\iota}_0 (0)_{n+1}^{2(L-1)} + \hat{\iota}_1 (1)_{n+1}^{2(L-1)} \right) = U(\tilde{\theta}_j) \frac{1}{\sqrt{2}} \left( (0)_{n+1}^{2(L-1)} + (1)_{n+1}^{2(L-1)} \right) = \mathcal{L}_U \left( \frac{1}{\sqrt{2}} (0) + (1) \right),
$$

which coincides with (22).

Extending the derivations to $n$ computational paths such that the paths realize the $n$-qubit unitary $U(N)$, each $A_i$ apply a Bell measurement $\mathcal{M}_B(A_i)$, thus the post-measurement network state $|\Phi'\rangle_{1}^n$ is as

$$
|\Phi'\rangle_{1}^n = U(N) \sum_{i,j} \left( \hat{\iota}_{ij} M [m_{ij}] (|L\rangle_{n+1}^{2L-1}) \right) = U(N) \left( \hat{\iota}_{1,0} \hat{\iota}_{2,0} \ldots \hat{\iota}_{n,0} (0)_{n+1}^{2(L-1)} + \hat{\iota}_{1,1} \hat{\iota}_{2,1} \ldots \hat{\iota}_{n,1} (1)_{n+1}^{2(L-1)} \right) = U(N) \left( \hat{\iota}_{0}^N (0)_{n+1}^{2(L-1)} + \hat{\iota}_{1}^N (1)_{n+1}^{2(L-1)} \right) = U(N) \frac{1}{\sqrt{2^n}} \left( (0)_{n+1}^{2(L-1)} + (1)_{n+1}^{2(L-1)} \right) = \mathcal{L}_U \left( (|+\rangle_1 |+\rangle_2 \ldots |+\rangle_N \right),
$$

where $\langle L \rangle_{n+1}^{2(L-1)} = \{ |0\rangle_{n+1}^{2(L-1)}, |1\rangle_{n+1}^{2(L-1)} \}$ defined on $\mathcal{H}_{L} = \mathbb{C}^{2^{2(n+1)-(L-1)}}$ since the entangled network structure of the distributed system is formulated via $2^{L-1}$ entangled states over the $n$ computational paths, while $n$ auxiliary qubit systems, $|aux\rangle_1 |aux\rangle_2 \ldots |aux\rangle_n$, are measured via the Bell measurements in the $n$ source nodes, $\mathcal{H}_{aux\ldots aux} = \mathbb{C}^{2^{2n}}$, that confirms the result in (27).

The $\mathcal{L}_D$ downloading process\(^{6,144}\) for receiver node $B_i$ results in

$$
\mathcal{L}_D \left( U(\tilde{\theta}_i) \frac{1}{\sqrt{2}} \left( (0)_{2}^{2(L-1)} + (1)_{2}^{2(L-1)} \right) \right) = U(\tilde{\theta}_i) |+\rangle_i, \quad (34)
$$

To obtain (34) in $B_i$, $M[m_b]$ local measurements in a $m_b$ suitable basis are applied on the remaining $2(L-1)-1$ qubits in the $L-1$ nodes of $\mathcal{P}(A_i \rightarrow B_i)$ between $A_i$ and $B_i$. Recalling the formalisms of\(^{144,145}\) for an $i$-th node, the $M[m_b]$ local measurement is set in bases $m_b \in \{m_0, m_1\}$, as

$$
M[m_0] = |\psi_0\rangle |0\rangle,
$$

and

$$
M[m_1] = |\psi_1\rangle |1\rangle,
$$

where $|\psi_0\rangle = \cos \frac{\zeta}{2} |0\rangle + e^{i\varphi} \sin \frac{\zeta}{2} |1\rangle$, $|\psi_1\rangle = \sin \frac{\zeta}{2} |0\rangle - e^{i\varphi} \cos \frac{\zeta}{2} |1\rangle$, with $\zeta \in [0, \pi]$. (Assuming that the entangled connections between the nodes are maximally entangled, $\zeta = \pi$, and $\zeta < \pi$ otherwise. This parameter is also referred to as entanglement factor, see also\(^{76}\). Then, it can be verified\(^{76,143}\) that by applying $M[m_b]$ local measurements in the $L-2$ intermediate nodes between $A_i$ and $B_i$ as defined by (35) and (36), Bob $B_i$ obtains the result $U(\tilde{\theta}_i) |+\rangle_i$ with probability $Pr \left( U(\tilde{\theta}_i) |+\rangle_i \right) = 1 - \cos \frac{\zeta}{2}$.

Therefore, applying the measurement procedure in the intermediate nodes of the $n$ computational paths, results in (28) at the receiver side in a distributed manner, as

$$
|\phi^*\rangle = \mathcal{L}_D \left( U(N) \frac{1}{\sqrt{2^n}} \left( (0)_{n+1}^{2(L-1)} + (1)_{n+1}^{2(L-1)} \right) \right),
$$

with probability

$$
Pr \left( |\phi^*\rangle \right) = \prod_{i=1}^{n} (1 - \cos \frac{\zeta}{2}) \quad (38)
$$

over the $n$ paths. Thus, if the network is maximally entangled it yields a deterministic download at the receiver.
The schematic model of the distributed physical system $N$ that realizes a scalable distributed quantum computation with arbitrary-level entangled connections. The $|s\rangle = |+\rangle_1 \ldots |+\rangle_n$ input system is distributed via $n$ source nodes $A_1, \ldots, A_n$ through a chain of intermediate nodes via $l$-level entangled connections to the $n$ receiver nodes $B_1, \ldots, B_n$, where $|+\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle), |s\rangle = \frac{1}{\sqrt{L}} \sum_z |z\rangle$, while $|z\rangle$ is an $n$-qubit length computational basis state. The aim of the distributed network system $N$ is to maximize a $C$ objective function of a computational problem in a distributed manner. The distributed system realizes the distributed unitary $U(N)$ and outputs a distributed system $|\phi^*\rangle = U(N)|s\rangle$. The $M$ distributed measurements are performed in the $n$ receiver nodes $B_1, \ldots, B_n$ to produce the string $z$ that allows the nodes to evaluate $C(z)$ in a distributed way. The $|s\rangle$ input system is uploaded via the $\mathcal{L}_U(|s\rangle) = \mathcal{L}_U(|+\rangle_1 \ldots |+\rangle_n)$ distributed uploading process to the distributed network state $|\Phi\rangle = U(N) \frac{1}{\sqrt{2}} \left((00\rangle_1^{2L(1-1)} + (11\rangle_1^{2L(1-1)}) \right) = U(N) \frac{1}{\sqrt{2}} \left((00\rangle_n^{2L(n+1)} + (11\rangle_n^{2L(n+1)}) \right)$, where $|\Phi_i\rangle = U\left(\frac{\theta_i}{\sqrt{2}}\right) \left((01\rangle_1^{2L(1-1)} + (10\rangle_1^{2L(1-1)}) \right)$, where index 1 identifies the first particle of computational path $\mathcal{P}(A_i \rightarrow B_i)$, formulated via the results of the unitaries of the $n$ computational paths, where an $i$-th path $\mathcal{P}(A_i \rightarrow B_i), i = 1, \ldots, n$, realizes an $U\left(\frac{\theta_i}{\sqrt{2}}\right) = U_{l_i} U_{l_{i-1}} \ldots U_{l_1}$ unitary sequence of $2L$ unitaries in $L$ nodes $V_x, x = 1, \ldots, L$, where $U_{l_i} = U\left(\beta_{i,i}, \gamma_{i,i}: U(\gamma_{i,i}), \gamma_{i,i}\right)$. The $\mathcal{L}_U(|s\rangle) = \mathcal{L}_U(|+\rangle_1 \ldots |+\rangle_n)$ uploading process is distributed among the $n$ nodes, where $\mathcal{L}_U(|+\rangle_i)$ is realized in an $i$-th source node $A_i$ as $\mathcal{L}_U(\alpha_i|0\rangle + \beta_i|1\rangle) = U\left(\frac{\theta_i}{\sqrt{2}}\right) \left(\alpha_i|0\rangle_1^{2L(1-1)} + \beta_i|1\rangle_1^{2L(1-1)} \right) = U\left(\frac{\theta_i}{\sqrt{2}}\right) \frac{1}{\sqrt{2}} \left((00\rangle_2^{2L(1-1)} + (11\rangle_2^{2L(1-1)}) \right)$, where $\mathcal{L}_D$ downloading process results in $\mathcal{L}_D \left(\frac{\gamma_i}{\sqrt{2}}\right) \left((00\rangle_2^{2L(1-1)} + (11\rangle_2^{2L(1-1)}) \right) = U\left(\frac{\gamma_i}{\sqrt{2}}\right)|+\rangle$, for receiver node $B_i$. Applying $\mathcal{L}_U$ and $\mathcal{L}_D$ for all source and receiver nodes, results in $\mathcal{L}_D(\mathcal{L}_U(|+\rangle_1 \ldots |+\rangle_n) = U(N)|s\rangle$ at the receiver in a distributed manner.

The proof is concluded here.

The system model of the scalable distributed physical system $N$ is depicted in Fig. 1. The schematic model of a computational path $\mathcal{P}(A \rightarrow B)$ in a distributed physical system $N$ is depicted in Fig. 2. (Local measurements of downloading procedure are not shown.)

**Ethics statement.** This work did not involve any active collection of human data.

**Quantum processing in a distributed quantum system**

**Theorem 1** An objective function $C$ can be maximized in the distributed quantum system $N$ via a target function $F = \sum_{(jk)\in N} F_{(jk)} = \max_{\phi^*} \langle \phi^*|C|\phi^*\rangle$, where $\langle \phi^*|\phi^*\rangle$ is an $l$-level, $l \geq 1$, entangled connection between qubits $j$ and $k$.

**Proof** Let $N$ be the physical distributed quantum system, with a particular objective function $C$ of a computational problem subject of a maximization. To simplify the discussion in the following section, allow us to focus on a single computational path $\mathcal{P}(A \rightarrow B)$, thus we set $n = 1$, and $N = \mathcal{P}(A \rightarrow B)$ with $|s\rangle = |+\rangle$; however, the derivations and results are not restricted to this case.

Let $U(\theta)$ be the unitary realized via the computational path $\mathcal{P}(A \rightarrow B)$, as

$$U(\theta) = U_{2L}(\theta_{2L}) U_{2L-1}(\theta_{2L-1}) \cdots U_1(\theta_1),$$

where $i = 1, \ldots, 2L$, $L$ is the number of nodes of $N$ (number of distributed subsystems), $2L$ is the total number of unitaries in the $L$ nodes (each node is defined via 2 unitaries) $\theta_i$ is a gate parameter associated with $U_i$, i.e., $\theta_i = \beta_i$ or $\theta_i = \gamma_i$, and $\theta$ is the gate parameter vector defined as
\[ \mathcal{P}(A \rightarrow B) \]

Figure 2. Evaluation of target function value \( F \) of a computational problem via a distributed computational path \( \mathcal{P}(A \rightarrow B) \) between a distant source node \( A \) and receiver node \( B \) in a distributed system \( N \) with \( L - 2 \) intermediate nodes \( V_x, x = 2, \ldots, L - 1 \), with multipartite entanglement in the local nodes. Alice applies an \( M_B \) Bell measurement on the input system \(|+\rangle\) and on the first particle of the chain to achieve the \( L_V(|+\rangle) \) uploading procedure. A node pair \( V_{xy} = \{V_x, V_y\} \) with a shared \( l \)-level entangled connection \( E_j \), \( j = 1, \ldots, L - 1 \) \((l = 1 \text{ for a small-scale system while } l \geq 1 \text{ for a medium- and large-scale system by a convention})\) is allowed to (1) apply a local coupling unitary \( U^C \) to connect qubits \( i \) (connected to \( V_{x-1} \)) to and from \( j \) in \( V_x \), and qubits \( k \) and \( k + 1 \) (connected to \( V_{x+1} \)) in (2) to perform a local single-qubit unitaries \( U(X_j, \beta_j) \) and \( U(X_k, \beta_k) \) on qubits \( j \) and \( k \) in \( V_x \) and \( V_y \), (3) to realize a distributed two-qubit unitary \( U(Z_j Z_k, \gamma_{jk}) \) on qubits \( j \) and \( k \) using the \( l \)-level entangled connection \( E_j \), and (4) to apply an \( M[m_b] \) in basis \( m_b \in \{m_0, m_1\} \), local measurement to realize the \( L_D \) download into \( B \). In a given \( V_x \), qubit \( j \) formulates a multipartite entanglement: \( j \) has an entangled connection with qubit \( k \) in \( V_y \), and \( j \) is also entangled with \( \Gamma_j \) other neighbor qubits, \( n_1, \ldots, n_r \), called remote entangled connections of \( j \) (not neighbors of qubit \( k \)), and the total number of qubits that are neighbors of \( j \) but not neighbors of \( k \) is \( \Gamma_j + 1 \). Each entangled connection \( E_j \) \( \delta \) has a contribution \( \xi_E \) to the expected target function value \( F_{\mathcal{P}(A \rightarrow B)} = \frac{1}{2} \sum_{\gamma,j=1}^{\Gamma_j} \xi_{E_j}. \) (Operations associated with a particular qubit in a given node are depicted by dashed circles.)

\[ \bar{\theta} = (\theta_1, \ldots, \theta_{2L-1}, \theta_{2L})^T. \] (40)

Assuming that \( N \) consist of \( g \) single-qubit unitaries and \( m \) two-qubit unitaries for the entangled qubit pairs \( (m \text{ qubit pair connection in } N) \), such that

\[ L = g + m, \] (41)

unitary \( U(\bar{\theta}) \) from (39) can be rewritten as

\[ U(\bar{\theta}) = U(B, \bar{\beta}) U(C, \bar{\gamma}), \] (42)

where

\[ U(B, \bar{\beta}) = \prod_{j=1}^g U(B_j, \beta_j), \] (43)

where \( \bar{\beta} \) is the gate parameter vector,

\[ \bar{\beta} = (\beta_1, \ldots, \beta_g)^T, \] (44)

and

\[ B = \sum_j B_j \] (45)

where \( B_j = X_j = \sigma_j^{z,14} \), and

\[ U(B_j, \beta_j) = \exp(-i\beta_j X_j), \] (46)

and \( U(C, \bar{\gamma}) \) is defined as\(^{14}\).
\[ U(C, \vec{\gamma}) = \prod_{(jk) \in N} U(C_{jk}, \gamma_{jk}), \] (47)

where \((jk) \in N\) is an \(l\)-level, \(l \geq 1\), entangled connection between qubits \(j\) and \(k\), with gate parameter vector
\[ \vec{\gamma} = (\gamma_1, \ldots, \gamma_m)^T, \]

and
\[ U(C_{jk}, \gamma_{jk}) = U(Z_j Z_k, \gamma_{jk} C_{jk}) = \exp\left(-i\gamma_{jk} C_{jk} Z_j Z_k\right), \] (48)

where \(Z_j Z_k = \sigma^Z_j \sigma^Z_k\). At a particular physical entangled connection topology in \(N\), the objective function \(C(z)\) can be written as
\[ C(z) = \sum_{(jk) \in N} C_{jk}(z), \] (49)

where \(C_{jk}(z)\) is the objective function component\(^{12,14}\) evaluated for entangled connection \((jk) \in N\), as
\[ C_{jk}(z) = \frac{1}{2} (1 - z_j z_k), \] (50)

where \(z\) is an \(n\)-length input bitstring,
\[ z = z_1 z_2 \ldots z_n, \] (51)

and \(z_i\) identifies an \(i\)-th bit, \(z_i \in \{-1, 1\}\). For a given \(z\), a \(|z\rangle\) computational basis state is defined as
\[ |z\rangle = |z_1 z_2 \ldots z_n\rangle \] (52)

and \(|\psi\rangle\) output system of \(N\) at a single path at input \((52)\) is defined as (For a level-\(p\) circuit, a set of \(p\ \vec{\beta}\) and \(\vec{\gamma}\) gate parameter vectors are used as \(\vec{\beta}^{(1)}, \ldots, \vec{\beta}^{(p)}\), and \(\vec{\gamma}^{(1)}, \ldots, \vec{\gamma}^{(p)}\). For simplicity, here we assume \(p = 1\), however the results can be extended for arbitrary \(p\)^{14}. For further details, see\(^{14}\).)
\[ |\psi\rangle = U\left(\vec{\beta}\right) |z\rangle \]
\[ = U\left(\vec{B}, \vec{\beta}\right) U(C, \vec{\gamma}) |z\rangle \]
\[ = U\left(\vec{B}, \vec{\beta}\right) \prod_{(jk) \in N} U(C_{jk}(z), \gamma_{jk}) |z\rangle \]
\[ = \prod_j \exp\left(-i\beta_j X_j\right) \prod_{(jk) \in N} \exp\left(-i\gamma_{jk} C_{jk}(z) Z_j Z_k\right) |z\rangle. \] (53)

Then, let \(|s\rangle\) be an \(n\)-qubit length input system of \(N\), defined as in \((19)\), thus for \(n = 1\),
\[ |s\rangle = |+\rangle, \] (54)

and the output system \(|\psi^*\rangle\) is evaluated as given in \((17)\). The maximization of objective function \(C\) is identified via a target function \(F\), as
\[ F = \max_{\vec{\gamma}} \langle \vec{\gamma}, \vec{\beta}, C\vert \vec{\gamma}, \vec{\beta}, C\rangle \]
\[ = \max_{\vec{\gamma}} \langle \psi^* \vert C \vert \psi^* \rangle, \] (55)

and for a particular entangled connection \((jk)\) of \(N\), the aim is the maximization of target function \(F_{(jk)}\), as
\[ F_{(jk)} = \max_{\vec{\gamma}} \left(-\frac{1}{2}\right) \langle \psi^*_{N,jk} \vert Z_j Z_k \vert \psi^*_{N,jk}\rangle, \] (56)

where \(|\psi^*_{N,jk}\rangle\) is a target state defined as
\[ |\psi^*_{N,jk}\rangle = |\gamma_{jk}, \beta_k, \beta_j, C_{jk}\rangle \]
\[ = U\left(\vec{B}, \beta_j\right) U\left(\vec{B}, \beta_k\right) U(C_{jk}(z), \gamma_{jk}) |s\rangle. \] (57)

For the total system \(N\), the objective function values of all entangled connections are summed, thus \(C(z)\) is as given in \((49)\). For all connected qubits, the target function is set as
\[
F = \sum_{\langle jk \rangle \in N} F_{\langle jk \rangle}
\]
\[
= \max_{\psi^*} \langle \psi^* | C | \psi^* \rangle
\]
\[
= \max_{\psi^*} \left( \frac{1}{2} \right) \sum_{\langle jk \rangle \in N} \left( \psi_{\langle jk \rangle}^* | C_{jk} | \psi_{\langle jk \rangle}^* \right)
\]
\[
= \left( \frac{1}{2} \right) \max_{\psi^*} \left( \sum_{\langle jk \rangle \in N} \left( \psi_{\langle jk \rangle}^* | Z_j Z_k | \psi_{\langle jk \rangle}^* \right) \right).
\]

where \( | \psi_{\langle jk \rangle}^* \rangle \) is given in (57).

Then, assuming that \( N \) consists of \( n \) computational paths, and \( |s \rangle \) is an \( n \)-qubit length input as defined in (19), the result in (58) can be extended as
\[
F = \sum_{\langle jk \rangle \in N} F_{\langle jk \rangle}
\]
\[
= \max_{\psi^*} \langle \psi^* | C | \psi^* \rangle,
\]
that concludes the proof.

**Distributed computational system as an extended correlation space.** Lemma 1 (The distributed computational space is an extended correlation space). The \( D(N) \) distributed computational space of \( N \) is an extended correlation space with \( n \) entangled computational paths, \( P(A_i \rightarrow B_i) \), \( i = 1, \ldots, n \) between \( n \) source and receiver nodes.

**Proof** Using the correlation space (The correlation space is an abstract mathematical model of a physical system defined via a matrix product state (MPS) representation and open-boundary conditions formalism, we first rewrite \( |\psi^* \rangle \) from (17), as
\[
|\psi^* \rangle = \sum_{x_{i=1} \ldots x_L} (B | x_{L} \rangle M[x_{L-1}] \ldots M[x_i] | A \rangle | x_{1} \rangle, \ldots, | x_{L} \rangle),
\]
where \( x_i \in \{0, 1\}, i = 1, \ldots, L, M[x_i] \) is a 2 \( \times \) 2 matrix, \( |x_i \rangle \) is a local state vector associated to node \( V_i \), as
\[
|x_i \rangle = c_0^{(i)} |0 \rangle + c_1^{(i)} |1 \rangle,
\]
and \( M[x_i] \) is defined as
\[
M[x_i] = z_0^{(i)} M[0] + z_1^{(i)} M[1],
\]
with relation
\[
(\langle x_{i=1} \ldots x_L | \psi_L \rangle) = (x_{L} | M[x_{L-1}] \ldots M[x_1] | +),
\]
where \( |+ \rangle = \frac{1}{\sqrt{2}} (|0 \rangle + |1 \rangle) \), while \( |A \rangle \) and \( |B \rangle \) are \( d \) dimensional vectors that represent the input and output systems (boundary conditions in the extended correlation space).

The system state of (60) can be rewritten as
\[
|\psi^* \rangle = \sum_{x_{i=1} \ldots x_L} (x_{L} | M[x_{L-1}] \ldots M[x_1] | +) | x_{1} \rangle, \ldots, | x_{L} \rangle).
\]
By recalling Observation 2 from, allows us to define \( \delta_i \) via the \( \zeta \in [0, \pi] \) measurement coefficient used in the definition of measurement operators (35) and (36), as
\[
\delta_i = \arg \left( \sin (\omega_i) + \cos (\omega_i) \exp \left( i \frac{\zeta}{2} \right) \right),
\]
where \( \omega_i \) identifies computational bases \( |b_{\omega_i} \rangle \in \{ |0_{\omega_i} \rangle, |1_{\omega_i} \rangle \} \), as
\[
|b_{\omega_i} \rangle = \begin{cases} 
|0_{\omega_i} \rangle = \sin (\omega_i) |0 \rangle + \cos (\omega_i) |1 \rangle \\
|1_{\omega_i} \rangle = \cos (\omega_i) |0 \rangle - \sin (\omega_i) |1 \rangle.
\end{cases}
\]
Using \( \omega_i \) along with \( \zeta \), a diagonal matrix \( D(\omega_i, \zeta) \) can be defined as
\[
D(\omega_i, \zeta) = \sqrt{P_i S(-2\delta_i)},
\]

https://doi.org/10.1038/s41598-020-76728-5
where
\[
S(x) = \text{diag}\left(e^{-\frac{i\pi}{2}}, e^{\frac{i\pi}{2}}\right).
\] (68)

while \(p_i\) is evaluated via (65) as
\[
p_i = |\delta_i|^2.
\] (69)

Finally, by exploiting Observation 3 of (45), leads to
\[
U(\tilde{\theta}) = WS(\delta_L) WS(\delta_{L-1}) \ldots WS(\delta_1),
\] (70)

where \(W\) is a matrix set as
\[
W = \exp\left(i\pi \frac{\delta}{2}\right),
\] (71)

where \(\tilde{\theta}\) is a coefficient, such that
\[
WS(\delta_j) = U_j = U(X_j, \beta_j)U(Z_jZ_k, \gamma_j),
\] (72)

where \(\delta_j\) is as given in (65) (with an index update).

Thus, the \(D(\mathcal{P}(A \rightarrow B))\) computational path is the map of the physical computational path
\[
\mathcal{P}(A \rightarrow B) = U_1 U_{L-1} \ldots U_1
\] (73)

formulated via the \(L\) nodes \(V_1, \ldots, V_L\) of \(N\) onto the correlation space, as
\[
D(\mathcal{P}(A \rightarrow B)) = WS(\delta_L) WS(\delta_{L-1}) \ldots WS(\delta_1).
\] (74)

Then using the system characterization of \(N\) of Section 2, reveals that \(D(N)\) is an extended correlation space with \(n\) computational paths, where an \(i\)-th computational path is evaluated as (74), thus the \(D(N)\) computational model of \(N\) is evaluated as
\[
D(N) = (W_1 S(\delta_{1,L}) W_1 S(\delta_{1,L-1}) \ldots W_1 S(\delta_{1,1})) \ldots
\]
\[
\ldots (W_n S(\delta_{n,L}) W_n S(\delta_{n,L-1}) \ldots W_n S(\delta_{n,1})),
\] (75)

where \((i,j)\) identifies a \(j\)-th unitary of an \(i\)-th computational path \(\mathcal{P}(A_i \rightarrow B_i)\), that concludes the proof. \(\square\)

**Objective function evaluation at multipartite entanglement.** Proposition 4 Let \(F_{\mathcal{P}(A \rightarrow B)}\) be the target function at a given objective function \(C_{\mathcal{P}(A \rightarrow B)}\) evaluated for the computational path \(\mathcal{P}(A \rightarrow B)\) via (58), as
\[
F_{\mathcal{P}(A \rightarrow B)} = \sum_{(jk) \in \mathcal{P}(A \rightarrow B)} F_{jk}
\]
\[
= \max_{\psi} \langle \psi^* | C_{\mathcal{P}(A \rightarrow B)} | \psi^* \rangle
\] (76)

\[
= \left(-\frac{1}{\sqrt{2}}\right)^r \max_{\psi \in \mathcal{P}(A \rightarrow B)} \left( \sum_{(jk) \in \mathcal{P}(A \rightarrow B)} \langle \psi^{N,j,k} | Z_jZ_k | \psi^{N,j,k} \rangle \right),
\]

where \(C_{\mathcal{P}(A \rightarrow B)}\) is defined as
\[
C_{\mathcal{P}(A \rightarrow B)} = \sum_{(jk) \in \mathcal{P}(A \rightarrow B)} C_{jk}.
\] (77)

**Theorem 2** (Scaling via gate parameters of unitaries). The \(F_{\mathcal{P}(A \rightarrow B)}\) target function of a computational path \(\mathcal{P}(A \rightarrow B)\) with objective function \(C_{\mathcal{P}(A \rightarrow B)} = \sum_{(jk) \in \mathcal{P}(A \rightarrow B)} C_{jk}\) is maximized at gate parameters \(\beta_j = \frac{\pi}{2}\) and \(\gamma_{jk} = \frac{1}{2} \cos^{-1}\left(\frac{\Gamma_j}{\Gamma_j + 1}\right)\) in the \(L\) nodes, where \(\Gamma_j\) is the number of remote entangled connections of \(j\).

**Proof** The proof utilizes the system model of Section 2, and focuses on a particular computational path \(\mathcal{P}(A \rightarrow B)\) with an \(C_{\mathcal{P}(A \rightarrow B)}\) objective function of a computational problem.

At \(L - 1\) entangled connections, \(F_{\mathcal{P}(A \rightarrow B)}\) from (76) can be written as
\[
F_{\mathcal{P}(A \rightarrow B)} = \frac{1}{2} \sum_{j=1}^{L-1} \xi_j,
\] (78)
where $\xi_{E_j}$ is the contribution of an $l$-level $E_j$ entangled connection between qubits $j$ and $k$ in target function $F_{\pi(A \rightarrow B_j)}$, defined as

$$\xi_{E_j} = \left( \sin \left( 2\beta_j + 2\beta_k \right) \right) \sin \gamma_{jk} \prod_{k=1}^{\Gamma_j+1} \cos \gamma_{jk}, \quad (79)$$

where $\Gamma_j$ is the number of remote neighbor entangled qubits of $j$ such that not neighbors of qubit $k$, while $\beta_j$, $\beta_k$ and $\gamma_{jk}$ are the gate parameters of unitaries of $U_{\pi_j}$ in (13) (The evaluation of (79) utilizes an abstraction. The structure of the distributed system is mapped onto a grid such that the vertices of the grid represent the qubits in the nodes, while an edge between the qubits identifies an $l$-level $E_j$ entangled connection in the distributed system. Since all connections between the qubits are entangled, the vertices on the grid are separated only by the particular edge that directly connects the qubits, thus the distance between the qubits on the grid is set to unit for all connections).)

Assuming that $\gamma_{jk}$ is set to the same value for all $k, k = 1, \ldots, \Gamma_j + 1$, at $\beta_j = \beta_k$ the result in (79) can be simplified as

$$\xi_{E_j} = \left( \sin 4\beta_j \right) \sin \gamma_{jk} \cos^{(\Gamma_j+1)} \gamma_{jk}. \quad (80)$$

To verify (79), we first rewrite (56) for a particular entangled connection $E_j$, as

$$F_{(jk)} = \left( -\frac{1}{2} \right) \langle \psi_{E_j}^* | Z_j Z_k | \psi_{E_j} \rangle$$

$$= \left( -\frac{1}{2} \right) \langle \psi_{E_j}^* | U^\dagger (N, \gamma_{jk}) (U^\dagger (\beta_j, X_j) Z_j U (\beta_j, X_j)) (U^\dagger (\beta_k, X_k) Z_k U (\beta_k, X_k)) U (N, \gamma_{jk}) | 1+ \rangle, \quad (81)$$

where $| \psi_{E_j}^* \rangle$ is the target state from (57), and

$$U (\beta_j, X_j) = \exp \left( -i\beta_j X_j \right) = \cos \left( \beta_j \right) I - i \sin \left( \beta_j \right) X_j \quad (82)$$

and

$$U (N, \gamma_{jk}) = \exp \left( -i\gamma_{jk} Z_j Z_k \right) = \cos \left( \gamma_{jk} \right) I - i \sin \left( \gamma_{jk} \right) Z_j Z_k, \quad (83)$$

where $N$ is a product of pairs of $Z$ operators. Then,

$$U^\dagger (\beta_j, X_j) Z_j U (\beta_j, X_j) (U^\dagger (\beta_k, X_k) Z_k U (\beta_k, X_k)) \quad \left(84\right)$$

where

$$\exp \left( i\beta_j X_j \right) Z_j \exp \left( -i\beta_j X_j \right)$$

$$= \left( \cos \left( \beta_j \right) I + i \sin \left( \beta_j \right) X_j \right) Z_j \left( \cos \left( \beta_j \right) I - i \sin \left( \beta_j \right) X_j \right)$$

$$= \left( \cos \left( \beta_j \right) Z_j + i \sin \left( \beta_j \right) Z_j X_j \right) \left( \cos \left( \beta_j \right) I - i \sin \left( \beta_j \right) X_j \right)$$

$$= \left( \cos \left( \beta_j \right) Z_j + i \sin \left( \beta_j \right) Y_j \right) \left( \cos \left( \beta_j \right) I - i \sin \left( \beta_j \right) X_j \right)$$

$$= \cos^2 \left( \beta_j \right) Z_j - i \cos \left( \beta_j \right) \sin \left( \beta_j \right) Z_j X_j + i \cos \left( \beta_j \right) \sin \left( \beta_j \right) Y_j - i^2 \sin^2 \left( \beta_j \right) Y_j X_j$$

$$= \cos^2 \left( \beta_j \right) Z_j + i \cos \left( \beta_j \right) \sin \left( \beta_j \right) X_j Y_j + i \cos \left( \beta_j \right) \sin \left( \beta_j \right) Y_j - i^2 \sin^2 \left( \beta_j \right) Y_j X_j$$

$$= \cos^2 \left( \beta_j \right) Z_j + i \cos \left( \beta_j \right) \sin \left( \beta_j \right) Y_j + i \cos \left( \beta_j \right) \sin \left( \beta_j \right) Y_j + i^2 \sin^2 \left( \beta_j \right) Z_j$$

$$= \left( \cos^2 \left( \beta_j \right) Z_j + i^2 \sin^2 \left( \beta_j \right) Z_j \right) + 2i \cos \left( \beta_j \right) \sin \left( \beta_j \right) Y_j$$

$$= \left( \frac{1}{2} (1 + \cos (2\beta_j)) Z_j - \frac{1}{2} (1 - \cos (2\beta_j)) Z_j \right) + 2i \left( \frac{1}{2} (\sin (2\beta_j) - \sin (0)) \right) Y_j$$

$$= \left( \frac{1}{2} Z_j + \frac{1}{2} \cos (2\beta_j) Z_j - \frac{1}{2} Z_j + \frac{1}{2} \cos (2\beta_j) Z_j \right) + i \sin (2\beta_j) Y_j$$

$$= Z_j \cos (2\beta_j) + i Y_j \sin (2\beta_j),$$

and
\[ \exp(i\beta_k X_k) Z_k \exp(-i\beta_k X_k) \]
\[ = (\cos(\beta_k) I + i \sin(\beta_k) X_k) Z_k (\cos(\beta_k) I - i \sin(\beta_k) X_k) \]
\[ = (\cos(\beta_k) Z_j + i \sin(\beta_k) Z_k) (\cos(\beta_k) I - i \sin(\beta_k) X_k) \]
\[ = (\cos(\beta_k) Z_j + i \sin(\beta_k) Y_k) (\cos(\beta_k) I - i \sin(\beta_k) X_k) \]
\[ = \cos^2(\beta_k) Z_k - i \cos(\beta_k) \sin(\beta_k) Z_j + i \tan(\beta_k) Y_k - i^2 \sin^2(\beta_k) Y_k X_k \]
\[ = \cos^2(\beta_k) Z_k + i \cos(\beta_k) \sin(\beta_k) Z_j + i \tan(\beta_k) Y_k - i^2 \sin^2(\beta_k) Y_k X_k \]  
(86)

thus

\[ U^\dagger(\beta_j, X_j) Z_j U(\beta_j, X_j) U^\dagger(\beta_k, X_k) Z_k U(\beta_k, X_k) \]
\[ = (Z_j \cos(\beta_j) + i Y_j \sin(\beta_j))(Z_k \cos(\beta_k) + i Y_k \sin(\beta_k)). \]  
(87)

Assuming, that \( \beta_j = \beta_k = \beta \), (87) can be written in a simplified form as

\[ U(\beta, X) Z_j Z_k U(\beta, X) \]
\[ = U^\dagger(\beta_j, X_j) Z_j U(\beta_j, X_j) U^\dagger(\beta_k, X_k) Z_k U(\beta_k, X_k) \]
\[ = \cos^2(\beta) Z_j Z_k + i \cos(2\beta) Y_j Y_k \cos(\beta) Y_j Y_k + i \sin(2\beta) Y_j Y_k + i^2 \sin^2(2\beta) Y_j Y_k. \]  
(88)

The related terms \( U(N, \gamma_jk) Z_j U^\dagger(N, \gamma_jk) \) and \( U(N, \gamma_jk) Y_j U^\dagger(N, \gamma_jk) \) of (81) are evaluated as

\[ U(N, \gamma_jk) Z_j U^\dagger(N, \gamma_jk) \]
\[ = (Z_j \cos(\gamma_j) I - i Z_j \sin(\gamma_j) Z_k) \]
\[ = (Z_j \cos(\gamma_j) I - i Z_j \sin(\gamma_j) Z_k) \cos(\gamma_j) I + i \sin(\gamma_j) Z_j Z_k \]
\[ = (Z_j \cos(\gamma_j) I - i Z_j \sin(\gamma_j) Z_k) \cos(\gamma_j) I + i \sin(\gamma_j) Z_j Z_k \]
\[ = \cos^2(\gamma_j) Z_j + i \cos(\gamma_j) \sin(\gamma_j) Z_k - i \cos(\gamma_j) \sin(\gamma_j) Z_k - i^2 \sin^2(\gamma_j) Z_j \]
\[ = \cos^2(\gamma_j) Z_j - i^2 \sin^2(\gamma_j) Z_j \]
\[ = \cos^2(\gamma_j) Z_j + i^2 \sin^2(\gamma_j) Z_j \]
\[ = \frac{1}{2}(1 + \cos(2\gamma_j)) Z_j + \frac{1}{2}(1 - \cos(2\gamma_j)) Z_j \]
\[ = \frac{1}{2} Z_j + \cos(2\gamma_j) Z_j + \frac{1}{2} Z_j - \cos(2\gamma_j) Z_j \]
\[ = Z_j, \]

and

\[ U(N, \gamma_jk) Y_j U^\dagger(N, \gamma_jk) \]
\[ = (\cos(\gamma_j) I - i \sin(\gamma_j) Z_j Z_k) Y_j \cos(\gamma_j) I + i \sin(\gamma_j) Z_j Z_k \]
\[ = (\cos(\gamma_j) Y_j - i \sin(\gamma_j) Y_j Z_j Z_k) \cos(\gamma_j) I + i \sin(\gamma_j) Z_j Z_k \]
\[ = (\cos(\gamma_j) Y_j - i \sin(\gamma_j) Y_j Z_j Z_k) \cos(\gamma_j) I + i \sin(\gamma_j) Z_j Z_k \]
\[ = \cos^2(\gamma_j) Y_j + i \cos(\gamma_j) \sin(\gamma_j) Y_j Z_j Z_k - i \sin(\gamma_j) \cos(\gamma_j) X_j Z_k Z_k - i^2 \sin^2(\gamma_j) X_j Z_k Z_k \]
\[ = \cos^2(\gamma_j) Y_j - i \cos(\gamma_j) \sin(\gamma_j) Z_j Z_k Z_j Z_k - i \sin(\gamma_j) \cos(\gamma_j) X_j Z_k + i^2 \sin^2(\gamma_j) Y_j \]
\[ = \cos^2(\gamma_j) Y_j - i \cos(\gamma_j) \sin(\gamma_j) Z_j Z_k - i \sin(\gamma_j) \cos(\gamma_j) X_j Z_k + i^2 \sin^2(\gamma_j) Y_j \]
\[ = (\frac{1}{2}(1 + \cos(2\gamma_j)) Y_j - \frac{1}{2}(1 - \cos(2\gamma_j)) Y_j - 2i(\frac{1}{2}(\sin(2\gamma_j) - \sin(0))) X_j Z_k \]
\[ = (\frac{1}{2} Y_j + \frac{1}{2} \cos(2\gamma_j) Y_j - \frac{1}{2} Y_j + \frac{1}{2} \cos(2\gamma_j) Y_j - 2i(\frac{1}{2}(\sin(2\gamma_j) - \sin(0))) X_j Z_k \]
\[ = Y_j \cos(2\gamma_j) - i X_j Z_k \sin(2\gamma_j). \]
Then, using (81), let $\chi_{jk}$ be defined as

$$\chi_{jk} = U^\dagger (N, \gamma_{jk}) \left( U^\dagger (\beta_j, X_j) Z_j U (\beta_j, X_j) \right) \left( U^\dagger (\beta_k, X_k) Z_k U (\beta_k, X_k) \right) U (N, \gamma_{jk})$$

(91)

thus (81) can be rewritten as

$$F_{(jk)} = \left(-\frac{1}{2}\right) \langle + | \chi_{jk} | + \rangle,$$

(92)

with

$$\langle + | X | + \rangle = 1,$$

(93)

and

$$\langle + | Z | + \rangle = \langle + | Y | + \rangle = 0.$$

(94)

It can be verified that $\chi_{jk}$ can be decomposed as

$$\chi_{jk} = \eta_j \eta_k,$$

(95)

where

$$\eta_j = Z_j \cos 2\beta_j + \left(Y_j \cos \gamma_{jk} - X_j Z_k \sin \gamma_{jk}\right) \sin 2\beta_j \prod_{k=1}^{\Gamma_j+1} \cos \gamma_{jk}$$

$$= Z_j \cos 2\beta_j + \left(Y_j \sin 2\beta_j \prod_{k=1}^{\Gamma_j} \cos \gamma_{jk} - X_j Z_k \sin \gamma_{jk} \sin 2\beta_j \prod_{k=1}^{\Gamma_j+1} \cos \gamma_{jk}\right)$$

(96)

and

$$\eta_k = Z_k \cos 2\beta_k + \left(Y_k \cos \gamma_{jk} - X_k Z_j \sin \gamma_{jk}\right) \sin 2\beta_k \prod_{k=1}^{\Gamma_j+1} \cos \gamma_{jk}$$

$$= Z_k \cos 2\beta_k + \left(Y_k \sin 2\beta_k \prod_{k=1}^{\Gamma_j} \cos \gamma_{jk} - X_k Z_j \sin \gamma_{jk} \sin 2\beta_k \prod_{k=1}^{\Gamma_j+1} \cos \gamma_{jk}\right).$$

(97)

Thus, $\chi_{jk}$ can be evaluated as
\[
\chi_{jk} = \left( Z_j \cos 2\beta_j + Y_j \sin 2\beta_j \prod_{k=1}^{\gamma_j} \cos \gamma_{jk} - X_j Z_k \sin \gamma_{jk} \sin 2\beta_j \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk} \right) 
\times \left( Z_k \cos 2\beta_k + Y_k \sin 2\beta_k \prod_{k=1}^{\gamma_j} \cos \gamma_{jk} - X_k Z_j \sin \gamma_{jk} \sin 2\beta_k \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk} \right)
\]

\[
= Z_j Z_k \cos 2\beta_j \cos 2\beta_k + Z_j Y_k \cos 2\beta_j \sin 2\beta_k \prod_{k=1}^{\gamma_j} \cos \gamma_{jk} 
- X_k \cos 2\beta_j \sin \gamma_{jk} \sin 2\beta_k \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk}
+ Y_j Z_k \sin 2\beta_j \prod_{k=1}^{\gamma_j} \cos \gamma_{jk} \cos 2\beta_k + Y_j Y_k \sin 2\beta_j \sin 2\beta_k \prod_{k=1}^{2\gamma_j+1} \cos \gamma_{jk}
- Y_j Z_j X_k \sin \gamma_{jk} \sin 2\beta_j \sin 2\beta_k \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk}
+ X_j \gamma_{jk} \sin 2\beta_j \sin 2\beta_k \prod_{k=1}^{2(\gamma_j+1)} \cos \gamma_{jk}
\]

(98)

Then, by utilizing the fact that input system \(|+\rangle\), and therefore also \(|s\rangle\), is an eigenstate of each \(X\) with eigenvalue \(1^{14}\) (see also (93) and (94)), the terms containing \(Y\) and \(Z\) vanish from (98), while \(X\) can be replaced as \(X = 1\). As follows, (98) can be rewritten as

\[
\chi_{jk} = -X_k \cos 2\beta_j \sin \gamma_{jk} \sin 2\beta_k \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk}
- X_j X_k \sin \gamma_{jk} \sin 2\beta_j \sin 2\beta_k \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk}
- X_j \cos 2\beta_k \sin \gamma_{jk} \sin 2\beta_j \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk} + X_j X_k \sin \gamma_{jk} \sin 2\beta_j \sin 2\beta_k \prod_{k=1}^{\gamma_j+1} \cos \gamma_{jk}
\]

(99)

Further assuming that \(\beta_j = \beta_k = \beta\) holds, (99) can be simplified as
\[
\chi_{jk} = -2 \cos 2\beta \sin \gamma_{jk} \sin 2\beta \prod_{k=1}^{l_j+1} \cos \gamma_{jk}.
\] (100)

Therefore, (92) is as
\[
F_{(jk)} = \frac{1}{2} \chi_{jk}
\]
\[
= \frac{1}{2} \left( \cos 2\beta_j \sin 2\beta_k + \cos 2\beta_k \sin 2\beta_j \right) \left( \sin \gamma_{jk} \prod_{k=1}^{\Gamma_{j+1}} \cos \gamma_{jk} \right)
\]
\[
= \frac{1}{2} \left( \sin (2\beta_j + 2\beta_k) - \frac{1}{2} \sin (2\beta_j - 2\beta_k) - \frac{1}{2} \sin (2\beta_k - 2\beta_j) \right) \left( \sin \gamma_{jk} \prod_{k=1}^{\Gamma_{j+1}} \cos \gamma_{jk} \right)
\]
\[
= \frac{1}{2} \sin (2\beta_j + 2\beta_k) \left( \sin \gamma_{jk} \prod_{k=1}^{\Gamma_{j+1}} \cos \gamma_{jk} \right),
\] (101)

which at condition \(\beta_j = \beta_k = \beta\) (which is the case for a maximization) simplifies as
\[
F_{(jk)} = \frac{1}{2} \sin (4\beta) \left( \sin \gamma_{jk} \prod_{k=1}^{\Gamma_{j+1}} \cos \gamma_{jk} \right)
\]
\[
= \frac{1}{2} \xi_{E_j}.
\] (102)

Then, using (79), the \(C_{\mathcal{P}(A \rightarrow B)}\) objective function of the \(\mathcal{P}(A \rightarrow B)\) computational path is evaluated as
\[
C_{\mathcal{P}(A \rightarrow B)} = \frac{1}{2} \phi_{\mathcal{P}(A \rightarrow B)} + \frac{1}{2} \sum_{j=1}^{L-1} \xi_{E_j},
\] (103)

where \(\phi_{\mathcal{P}(A \rightarrow B)}\) identifies the total number of entangled connections of \(\mathcal{P}(A \rightarrow B)\), as
\[
\phi_{\mathcal{P}(A \rightarrow B)} = \frac{1}{2} \sum_{j=1}^{L-1} (\Gamma_j + 2) + \frac{1}{2},
\] (104)

where the term \(+\frac{1}{2} = \frac{1}{2}(+1)\) indicates the coupling unitary \(U_{E_j}^C = \exp \left( -i\hbar H^{(k,B)} \right)\) in node \(B\) in the evaluation \(C_{\mathcal{P}(A \rightarrow B)}\), by a convention.

Assuming that (80) holds, (103) is simplified as
\[
C_{\mathcal{P}(A \rightarrow B)} = \frac{1}{4} + \frac{1}{2} \sum_{j=1}^{L-1} (\Gamma_j + 2) + \frac{1}{2} \sum_{j=1}^{L-1} (\sin 4\beta_j) \sin \gamma_{jk} \cos (\Gamma_{j+1}) \gamma_{jk}
\]
\[
= \frac{1}{4} + \frac{1}{2} \sum_{j=1}^{L-1} \frac{1}{2} (\Gamma_j + 2) + (\sin 4\beta_j) \sin \gamma_{jk} \cos (\Gamma_{j+1}) \gamma_{jk}.
\] (105)

If for each node the same \(\beta_j, \gamma_{jk}\) and \(l_j\) values are set, (105) can be rewritten as
\[
C_{\mathcal{P}(A \rightarrow B)} = \frac{1}{4} + \frac{1}{2} (L - 1) \left( \frac{1}{2} (\Gamma_j + 2) + (\sin 4\beta_j) \sin \gamma_{jk} \cos (\Gamma_{j+1}) \gamma_{jk} \right).
\] (106)

After some calculations, the gate-parameter values \(\beta_j\) and \(\gamma_{jk}\) that maximize \(\xi_{E_j}\) (and therefore \(C_{\mathcal{P}(A \rightarrow B)}\)) are at
\[4 \cos 4\beta_j = 0\] (107)

and
\[
\cos (\Gamma_{j+2}) \gamma_{jk} - (\Gamma_j + 1) \cos (\Gamma_j) \gamma_{jk} \sin^2 \gamma_{jk} = 0,
\] (108)

that yields gate parameter values
\[
\beta_j = \frac{\pi}{4},
\] (109)

and
\[
\gamma_{jk} = \frac{1}{2} \cos^{-1} \left( \frac{\Gamma_j - 1}{\Gamma_{j+1}} \right).
\] (110)
Thus, (102) is maximized as

\[ F_{\beta k} = \frac{1}{4} \sin \left( \frac{\pi}{4} \right) \left( \sin \left( \frac{\pi}{2} \cos^{-1} \left( \frac{r_{j-1}}{r_{j} + r_{j+1}} \right) \right) \prod_{k=1}^{r_{j+1}} \cos \left( \frac{\pi}{2} \cos^{-1} \left( \frac{r_{j-1}}{r_{j} + r_{j+1}} \right) \right) \right). \]  

(111)

The maximized \( C_{P(A \to B)} \) objective function value of (105) for a given computational path is therefore

\[ C_{P(A \to B)} = \frac{1}{4} + \frac{1}{2} \sum_{j=1}^{r_{j+1}} \left( \Gamma_{j} + 2 \right) + \left( \sin \frac{\pi}{4} \right) \left( \sin \left( \frac{\pi}{2} \cos^{-1} \left( \frac{r_{j-1}}{r_{j} + r_{j+1}} \right) \right) \right) \cos^{(r_{j+1})} \left( \frac{\pi}{2} \cos^{-1} \left( \frac{r_{j-1}}{r_{j} + r_{j+1}} \right) \right) \]  

(112)

and the maximized value of (106) is as

\[ C_{P(A \to B)} = \frac{1}{4} + \frac{1}{2} \sum_{j=1}^{r_{j+1}} \left( \Gamma_{j} + 2 \right) + \left( \sin \frac{\pi}{4} \right) \left( \sin \left( \frac{\pi}{2} \cos^{-1} \left( \frac{r_{j-1}}{r_{j} + r_{j+1}} \right) \right) \right) \cos^{(r_{j+1})} \left( \frac{\pi}{2} \cos^{-1} \left( \frac{r_{j-1}}{r_{j} + r_{j+1}} \right) \right) \]  

(112)

Figure 3. The values of \( \zeta_{Ej} \) in function of gate parameters \( \beta_{j} \) and \( \gamma_{j} = \frac{1}{2} \gamma_{jk} \) for different \( \Gamma_{j} \) values (\( \gamma_{jk} \) is set for the same value for all \( k, k = 1, \ldots, \Gamma_{j} + 1 \)). (a) \( \Gamma_{j} = 0 \) (b) \( \Gamma_{j} = 1 \) (c) \( \Gamma_{j} = 2 \) (d) \( \Gamma_{j} = 3 \) (e) \( \Gamma_{j} = 4 \) (f) \( \Gamma_{j} = 5 \) (g) \( \Gamma_{j} = 6 \) (h) \( \Gamma_{j} = 7 \) (i) \( \Gamma_{j} = 8 \).
The proof is concluded here.

The values of $\zeta_j$ in function of gate parameters $\beta_j$ and $\gamma_j = \frac{1}{2} \gamma_j k$, for different $L$ and $\Gamma_j$ ($\beta_j$ and $\gamma_j$ are set for the same values for all $j, k = 1, \ldots, \Gamma_j + 1$) are depicted in Fig. 3.

The objective function values (106) for a computational path $P(A \rightarrow B)$ in function of gate parameters $\beta_j$ and $\gamma_j = \frac{1}{2} \gamma_j k$, at different $L$ node number and $\Gamma_j$ values ($\beta_j$ and $\gamma_j$ are set as the same for all $j$, $k = 1, \ldots, \Gamma_j + 1$) are depicted in Fig. 4.

The gate parameter values $\beta_j$ and $\gamma_j k$ for the maximization of $\zeta_j$ are depicted in Fig. 5.

$$C_{P(A \rightarrow B)} = \frac{1}{4} + \frac{1}{2} (L - 1) \left( \frac{1}{4} (\Gamma_j + 2) + \sin \left( \frac{T}{2} - \frac{1}{2} \sin^{-1} \left( \frac{\Gamma_j - 1}{\Gamma_j + 1} \right) \right) \cos^{(\Gamma_j + 1)} \left( \frac{T}{4} - \frac{1}{2} \sin^{-1} \left( \frac{\Gamma_j - 1}{\Gamma_j + 1} \right) \right) \right).$$

(113)

The proof is concluded here.

Figure 4. The $C_{P(A \rightarrow B)}$ objective function values for a computational path $P(A \rightarrow B)$ in function of gate parameters $\beta_j$ and $\gamma_j = \frac{1}{2} \gamma_j k$, for different $L$ and $\Gamma_j$ ($\beta_j$ and $\gamma_j$ are set for the same values for all $j, j = 1, \ldots, L - 1$ and $k, k = 1, \ldots, \Gamma_j + 1$). (a) $L = 2, \Gamma_j = 0$ (b) $L = 10, \Gamma_j = 0$ (c) $L = 100, \Gamma_j = 0$ (d) $L = 2, \Gamma_j = 3$ (e) $L = 10, \Gamma_j = 3$ (f) $L = 100, \Gamma_j = 3$ (g) $L = 2, \Gamma_j = 6$ (h) $L = 10, \Gamma_j = 6$ (i) $L = 100, \Gamma_j = 6$.
Scaling of a distributed quantum processing

Target function scaling at a decoherence. Let $S_{j,k}(t)$ be the time evolution of target state $|\psi_{j,k}(t)\rangle$ defined at a particular $t$, as

$$S_{j,k}(t) = \left| \langle \psi_{j,k}(t_0) | \psi_{j,k}(t) \rangle \right|^2,$$

where $|\psi_{j,k}(t)\rangle$ is defined via (57), as a target state at $t$, as

$$|\psi_{j,k}(t)\rangle = |\gamma_{j,k}(t), \beta_k(t), \beta_j(t), N\rangle = U(B, \beta_j(t)) U(B, \beta_k(t)) U(N, \gamma_{j,k}(t)) |s\rangle,$$

where $\beta_j(t), \beta_k(t)$ and $\gamma_{j,k}(t)$ are values of the gate parameters at a given time $t$ associated to $\langle ij \rangle$, while $|\psi_{j,k}(t_0)\rangle$ is an initial state at some $t_0 \in [0, T]$, while $A(t)$ is the survival amplitude, defined as

$$A(t) = \langle \psi_{j,k}(t_0) | \hat{U}(t, t_0) | \psi_{j,k}(t_0) \rangle,$$

where $\hat{U}(t, t_0)$ is the time evolution operator generated by a Hamiltonian $\hat{H}$, as

$$\hat{U}(t, t_0) = T \exp \left( -i \int_{t_0}^{t} dx \hat{H}(x) / \hbar \right).$$

From the exponential decay law, (116) can be written as

$$A(t) = e^{-\Delta t},$$

where $\Delta$ is the decay rate.

Proposition 5 The $F_{j,k}(t)$ is the target function $F_{j,k}$ from (56) at a given $t$, defined as

$$F_{j,k}(t) = \max_{\theta} \left( -\frac{1}{2} \langle \psi_{j,k}(t) | Z_j Z_k | \psi_{j,k}(t) \rangle \right).$$

Theorem 3 (Target function scaling at decoherence). At an systemal decoherence, for any non-zero quantum decay $\Delta$ on $\langle ij \rangle$, the $F(\langle ij \rangle)$ target function is scalable via the local $M[m_b]$ measurement operator of the $L_D$ download procedure.

Proof Let assume that the total number of entangled connections of $N$ is $D = n(L - 1)$. Then, let $t_{ij}(N)$ be a vector of initialization time parameters of the target states of the entangled connections, defined as

Figure 5. Gate parameter values $\beta_j$ and $\gamma_{jk}$ in function of $\Gamma_j$ for the maximization of $\zeta_{Ej}$ in the distributed system $N$. 

\[ t_{(j)}(N) = \left(t_{0}^{(1)}, \ldots, t_{0}^{(D)}\right)^{T}, \]  

where \( t_{0}^{(j)} \in [0, T] \) is the initialization time (an initial time value when the target state is prepared) of target state \( \varphi^{*}_{N,jk}(t_{0}) \), \( j = 1, \ldots, D \).

For the survival amplitudes of the system states associated to the entangled connections at a given \( t \), we also define a \( A_{N}(t) \) vector of survival amplitudes associated to the \( D \) target states, as

\[ A_{N}(t) = \left(A^{(1)}(t), \ldots, A^{(D)}(t)\right)^{T} = \left(e^{-\Delta_{i}t}, \ldots, e^{-\Delta_{i}t}\right)^{T}, \]  

where \( A^{(i)}(t) \) is the survival amplitude of \( \left| \varphi^{*}_{N,jk}(t) \right\rangle \), while \( \Delta_{i} \) is the decay rate belongs to \( A^{(i)}(t) \) defined via \( \hat{U}(t, t_{0}^{(i)}) \) that evolves \( \left| \varphi^{*}_{N,jk}(t) \right\rangle \) to \( \left| \varphi^{*}_{N,jk}(t) \right\rangle \).

Then, let \( \ell_{D} \) be a downloading procedure that requires the utilization of \( M[m_{b}] \) local measurements for the localization onto the target nodes with a measurement vector \( M(N) \), as

\[ M(N) = \left(M\left(\tau^{(1)}\right)[m_{b}], \ldots, M\left(\tau^{(2D)}\right)[m_{b}]\right)^{T}, \]  

where \( M\left(\tau^{(i)}\right)[m_{b}] \) identifies a measurement \( M[m_{b}] \) on qubit \( j \) of \( jk \) at time \( \tau^{(i)} \in [0, T] \) in \( N, i = 1, \ldots, 2D \), as

\[ M\left(\tau^{(i)}\right)[m_{b}] = \begin{cases} 1, \text{if } j \text{ is measured at } \tau^{(i)} \\ 0, \text{otherwise.} \end{cases} \]  

Using (118), for a given qubit \( j \), we define the \( \mu_{j}(t) \) cumulated target state intensity which is dynamic term to model the interaction within the entangled network structure, as follows. Term \( \mu_{j}(t) \) is defined as the sum of weighted target state decoherence terms (weighted target state intensities) of existing neighboring entangled connections and the actual weighted target state intensity at a local decoherence (local target function intensity), as

\[ \mu_{j}(t) = \Lambda_{jk}(t, t_{0}^{(j)}) + \sum_{l=1,j\neq k}^{\Gamma_{j}+1} \Lambda_{jl}(t, t_{0}^{(j)} < t) \]

\[ = F_{jk}(t_{0}^{(j)})A_{j}(t, t_{0}^{(j)}) + \sum_{l=1,j\neq k}^{\Gamma_{j}+1} \int_{0}^{t} \Lambda_{jl}(t, s) dG_{l}(s) \]

\[ = F_{jk}(t_{0}^{(j)})A_{j}(t, t_{0}^{(j)}) + \sum_{l=1,j\neq k}^{\Gamma_{j}+1} \int_{0}^{t} F_{jl}(t_{0}^{(k)})A_{l}(t, s) dG_{l}(s) \]

\[ = F_{jk}(t_{0}^{(j)})e^{-\Delta_{l}(t-t_{0}^{(j)})} + \sum_{l=1,j\neq k}^{\Gamma_{j}+1} \int_{0}^{t} F_{jl}(t_{0}^{(k)})e^{-\Delta_{l}(t-s)} dG_{l}(s), \]  

where term \( \Lambda_{jk}(t, t_{0}^{(j)}) \) is defined as the intensity of a target state \( \left| \varphi^{*}_{N,jk}(t) \right\rangle \),

\[ \Lambda_{jk}(t, t_{0}^{(j)}) = F_{jk}(t_{0}^{(j)})A_{j}(t, t_{0}^{(j)}) \]

\[ = F_{jk}(t_{0}^{(j)})e^{-\Delta_{l}(t-t_{0}^{(j)})}, \]  

where \( A_{j}(t, t_{0}^{(j)}) = e^{-\Delta_{l}(t-t_{0}^{(j)})} \) is the survival amplitude of \( \left| \varphi^{*}_{N,jk}(t) \right\rangle \) such that the target state is initialized at \( t_{0}^{(j)} \), \( F_{jk}(t_{0}^{(j)}) \) is the initial target function value at \( t_{0}^{(j)} \), while \( (j\ell) \) refer to the neighboring entangled connections of \( j, l = 1, \ldots, (\Gamma_{j}+2) - 1, l \neq k \), while \( G_{l}(s) \) is a control parameter \( t_{0}^{(j)} \), defined as

\[ G_{l}(s) = \begin{cases} 0, \text{if } s < t_{0}^{(j)} \\ 1, \text{if } s \geq t_{0}^{(j)}, \end{cases} \]  

where \( s \leq T \).

Using (124), the \( \mu_{N}(t) = (\mu_{1}(t), \ldots, \mu_{D}(t))^{T} \) cumulated target state intensity of \( N \) can be defined as

\[ \mu_{N}(t) = \Lambda_{N}(t) + \int_{0}^{t} F_{N}(t_{0})A_{N}(t, s) dG_{N}(s), \]  

(127)
where $\Lambda_N(t)$ is the vector of target state intensities of $N$

$$\Lambda_N(t) = \Lambda_1(t, t_0^{(1)}), \ldots, \Lambda_D(t, t_0^{(D)})^T,$$  \hspace{1cm} (128)

and

$$F_N(t_0)A_N(t, s) = \left[ F_{(\rho)}(t_0^{(i)})A_i(t, s) \right]_{j,j=1,...,j=\Gamma_i+1,j\neq k} = \left[ F_{(\rho)}(t_0^{(i)}) \right] e^{-\Delta_i(t-s)}_{j,j=1,...,j=\Gamma_i+1,j\neq k},$$ \hspace{1cm} (129)

while $G_N(s)$ is a vector of control parameters

$$G_N(s) = (G_1(t), \ldots, G_D(t))^T.$$ \hspace{1cm} (130)

At that point, our aim is to reveal the impacts of a $M[m_b]$ local measurement (performed in the $\mathcal{L}_D$ downloading phase) on the $\mu_N(t)$ cumulated target function intensity $(127)$, i.e., to describe the impact of a local measurement and the localization process on the global entangled network structure.

Let us assume that a $M[m_b]$ measurement is performed on a qubit $j$ of $(j,k)$ at $\tau^{(i)} \in [0, T]$, denoted by $M(\tau^{(i)})[m_b]$. Then, let $\mu_N(t, \tau^{(i)})$ refer to the resulting cumulated target state intensity of $N$, evaluated as

$$\mu_N(t, \tau^{(i)}) = \left( \Lambda_N(t) + \int_{0}^{\tau^{(i)}} F_N(t_0)A_N(t, s)dG_N(s) \right) \circ h_N(j) \circ D(B)$$ \hspace{1cm} (131)

where $\circ$ denotes element-wise product, $h_N(j)$ is a vector with indicators $h_{(xy)}$ to identify the localized entangled connections of $N$ that are entangled with qubit $j$, as

$$h_{(xy)} = \begin{cases} 0, & \text{if } x = j \\ 1, & \text{otherwise} \end{cases}$$ \hspace{1cm} (132)

where $h_{(xy)}$ is an indicator associated to $\langle xy \rangle$. Let $G_N(s, h(N))$ be defined as$

$$G_N(s, h(N)) = G_N^{\tau^{(i)}}(s, h(N)) + G_N^{\tau^{(i)}-\tau^{(i)}}(s, h(N)),$$ \hspace{1cm} (133)

while $G_N^{\tau^{(i)}}(s, h(N))$ is an indicator for $t \leq \tau^{(i)}$ (i.e., $G_N^{\tau^{(i)}}(s, h(N))$ indicates the target state intensity before the localization in the intermediate node where the measurement is performed), while $G_N^{\tau^{(i)}-\tau^{(i)}}(s, h(N))$ is set for $t > \tau^{(i)}$ (i.e., $G_N^{\tau^{(i)}-\tau^{(i)}}(s, h(N))$ indicates the target state intensity after the localization onto the receiver node), and $D(B) = (B_1, \ldots, B_n)^T$ is a vector of $n$ receivers for the localization procedure of target state intensity in the $\mathcal{L}_D$ downloading procedure, as

$$B_i = \begin{cases} 1, & \text{if } j \in \mathcal{P}(A_i \rightarrow B_i) \\ 0, & \text{otherwise} \end{cases}$$ \hspace{1cm} (134)

thus, if $j$ belongs to the computational path $\mathcal{P}(A_i \rightarrow B_i)$ then $B_i$ is a target node in $\mathcal{L}_D$.

As follows, the $\mu_N(t, \tau^{(i)})$ cumulated target state intensity of the global entangled structure can be decomposed into a sum of target state intensities before measurement $M(\tau^{(i)})[m_b]$ in the intermediate nodes, and after measurement in the target node. As a corollary of the $M(\tau^{(i)})[m_b]$ measurement on $j$, for any $t \leq \tau^{(i)}$, the target state intensities of connections entangled with $j$ vanish from the cumulated target state intensity in the intermediate nodes.

As the measurement on $j$ is performed in the intermediate node, we focus to Bob $B_i$, to evaluate the target state intensity on his localized system state. As follows, at Bob $B_i$, the target state intensity of the localized system is as

$$\mu_{B_i}(t, \tau^{(i)}) = \Lambda_{B_i}(t) + \int_{0}^{\tau^{(i)}} F_{B_i}(t_0)(t)A_{B_i}(t, s)dG_{B_i}^{\tau^{(i)}-\tau^{(i)}}(s, h(N))$$ \hspace{1cm} (135)

$$= F_{(\rho)}(t_0^{(i)}) e^{-\Delta_i(t-s)} + \sum_{l=1, l\neq k}^{r_i+1} \int_{0}^{\tau^{(i)}} F_{(\rho)}(t_0^{(i)}) e^{-\Delta_i(t-s)}dG_{B_i}^{\tau^{(i)}-\tau^{(i)}}(s, h(N)),$$
where index $B_i$ refers to the localized terms at Bob $B_i$.

The remaining, non-localized target function intensity belongs to the entangled connections in the intermediate network is evaluated as

$$
\mu_N(t, \tau^{(j)}) = \Lambda_N(t) + \int_0^{\tau^{(j)}} F_N(t_0) \Lambda_N(t, s) dG_N(t, h(N))
$$

therefore the target state intensities evolves further in the intermediate network, where the term $h_N(j)$ indicates that the entangled connections that affected by the measurement are vanished out from the cumulated intensity value.

Utilizing the framework of148–150, (131) can be rewritten in a closed-form as

$$
\mu_N(t, \tau^{(j)}) = \nu_{B_i}(t) \Lambda_{B_i}(t)
$$

where

$$
\nu_{B_i}(t) = I + \int_0^{\tau^{(j)}} F_{B_i}(t_0) A_{B_i}(t, s) dG_{B_i}(s),
$$

while $\nu_{B_i}(t)$ is a matrix function148,149 associated to Bob's localized system, as

where $\Lambda_{B_i}$ is a vector of decay rates of the localized entangled connections.

**Figure 6.** Scaling of the $A_j \left( t, t_0^{(j)} \right)$ survival amplitude of the $\Lambda_{B_i}(t)$ target function intensity, $\Delta_j \in [10^{-3}, 10^{-2}]$, $\tau^{(j)} \in [0, 25]$, $t_0^{(j)} = 0$. 
Since the target function values $F(\langle jk \rangle_\tau)$ are determined by $\left| \varphi^{*}_{N,jk}(t) \right|$, it follows that at a target state decoherence the $F(\langle jk \rangle_\tau)$ target function values are therefore scalable via the $M[m_i]$ measurement associated to the localization procedure of the $L_D$ downloading in the intermediate nodes.

The proof is concluded here. \hspace{1em} \square

The scaled $A_j(t, t_0^{(j)})$ survival amplitude of the $\Lambda_{ij}(t)$ target function intensity of a given $\langle jk \rangle$ at different $\tau^{(j)}$ measurement delays and $\Delta_j$ decay rates are depicted in Fig. 6.

**Scaled computational cost. Lemma 2** (Cost of target function evaluation). The $fC(F(\langle jk \rangle))$ computational cost associated to a given $F(\langle jk \rangle)$ is the total application time of the local unitaries. The cost function is scalable via $\Gamma_j$ in a multipartite entanglement system.

**Proof** Let $P(A \rightarrow B)$ be a computational path in $N$ with $L$ nodes and $(L - 1)$ entangled connections. Then, for a given $\langle jk \rangle \in N$, let $\beta_j^*, \beta_k^*$ and $\gamma_{jk}^*$ refer to the gate parameters set to maximize the target function $F(\langle jk \rangle)$, set via (109) and (110).

The $fC(F_{P(A \rightarrow B)})$ computational cost of the maximization of target function $F_{P(A \rightarrow B)}$ is defined as

$$fC(F_{P(A \rightarrow B)}) = \sum_{\langle jk \rangle \in P(A \rightarrow B)} fC(F(\langle jk \rangle)),$$

where $fC(F(\langle jk \rangle))$ is the computational cost associated to a given $F(\langle jk \rangle)$ of an entangled connection $\langle jk \rangle$, as

$$fC(F(\langle jk \rangle)) = \beta_j^* + \beta_k^* + \gamma_{jk}^* = \frac{\pi}{4} + \frac{1}{2} \cos^{-1} \left( \frac{\Gamma_j - 1}{\Gamma_j + 1} \right).$$

that measures the computational cost as the total application time of the local unitaries.

As follows, (141) depends only on $\Gamma_j$, thus the scaling coefficient of the computational cost is $\Gamma_j$.

The $S_R(fC(F(\langle jk \rangle)))$ series representation of (142) for $\left| \frac{\Gamma_j}{(1 + \Gamma_j)} \right| < 1$, is

$$S_R(fC(F(\langle jk \rangle))) = \frac{\pi}{4} \left( 2 \cos^{-1} \left( \frac{\Gamma_j - 1}{\Gamma_j + 1} \right) + \pi \right),$$

$$= \frac{\pi}{4} - \sqrt{\frac{\Gamma_j}{\Gamma_j + 1}} \sum_{k=0}^{\infty} \frac{(\frac{1}{2})^k (\frac{\Gamma_j}{\Gamma_j + 1})^k}{2k! + k!},$$

while the $S_E(fC(F(\langle jk \rangle)))$ series expansion of (142) at $\Gamma_j = \infty$ is as

$$S(fC(F(\langle jk \rangle))) = \frac{\pi}{4} + \sqrt{\frac{\Gamma_j}{\Gamma_j - 1}} - \frac{3}{8} \left( \frac{1}{\Gamma_j} \right)^{3/2} + \frac{3}{8} \left( \frac{1}{\Gamma_j} \right)^{5/2} - \frac{1}{8} \left( \frac{1}{\Gamma_j} \right)^{7/2} + \frac{1}{8} \left( \frac{1}{\Gamma_j} \right)^{9/2} + O \left( \left( \frac{1}{\Gamma_j} \right)^{5/2} \right).$$

The $fC(N)$ total computational cost of $N$ at $n$ computational paths, is therefore
\[ f_c(N) = \sum_{q=1}^{n} f_c(F_{P_q}) = \sum_{q=1}^{n} \sum_{\langle k \rangle \in P_q} f_c(F_{\langle k \rangle}). \] (145)

In Fig. 7, the scaled \(f_c(F_{\langle k \rangle})\) cost function of \(F_{\langle k \rangle}\) is depicted.

Conclusions
Here, we defined a scalable model of distributed gate-model quantum computation in near-term quantum systems. We evaluated the scaling attributes and the unitaries of a distributed system for solving optimization problems. We showed that the computational model is an extended correlation space. We studied how decoherence affects the distributed computational model and characterized a cost function. The proposed results are applicable in different scenarios of experimental gate-model quantum computations.

Data availability
This work does not have any experimental data.
