Spatiotemporal Analysis; Haemorrhagic Fever with Renal Syndrome; Meteorological Factors; Autoregressive Integrated Moving Average (ARIMA) Model; Prediction
Abstract

Background: The purpose of this study was to explore the dynamics of the occurrence of haemorrhagic fever with renal syndrome (HFRS) and find the potential spatiotemporal factors leading to the incidence of HFRS in Anqiu City. Methods: Monthly reported cases of HFRS and climatic data for 2000–2014 in Anqiu City were obtained. An autoregressive integrated moving average (ARIMA) model was used to fit the HFRS incidence prediction model and predict the epidemic trend in Anqiu City. Multiple linear regression method was used to analyze the temporal relationship between HFRS incidence and meteorological factors during the study period. Results: Spatial analysis results indicated that the annualized average incidence at the town level ranged from 2.18 to 6.09 per 100,000 among 14 towns, and the western towns in Anqiu City exhibited high endemic levels during the study periods. With high validity, the optimal ARIMA (0, 1, 1) × (0, 1, 1)12 model could be used to predict the HFRS incidence in Anqiu City in 2014. The monthly trend in HFRS incidence was negatively associated with temperature and precipitation and positively associated with average wind speed. Multiple linear regression models showed that precipitation and relative wind speed were key climatic factors contributing to the transmission of HFRS. Conclusions: This study provides evidence that the ARIMA model can be used to fit the fluctuations in HFRS frequency in Anqiu City. Our findings add to the knowledge of the role played by climate factors in HFRS transmission in Anqiu City and can assist local health authorities in the development/refinement of a better strategy to prevent HFRS transmission.

Background

Haemorrhagic fever with renal syndrome (HFRS) is an acute viral syndrome caused by infection with one variety of hantavirus. HFRS is an important infectious disease in
developing countries [1].

In mainland China, HFRS remains a serious public health problem, with approximately 20,000-50,000 human cases reported annually, approximately 90% of the total cases worldwide[3].

Currently, HFRS is endemic in 28 of the 31 provinces in mainland China, and the highest incidence was reported in the middle and eastern part of China. Shandong Province, a highly developed coastal province, is one of the most severely affected provinces in China[5].

In order to effectively prevent the spread of HFRS, the Chinese Center for Disease Control and Prevention (CDC) established a surveillance system for HFRS in 2004 and created educational programmes for the general public. It is difficult to eliminate HFRS completely because many factors, such as diverse animal reservoirs and climate factors, may influence the control effects. Many studies have suggested that epidemic modelling and forecasting can be important and effective tools to prevent and control HFRS[7-9].

The development and application of an HFRS incidence forecasting model are effective for improving the understanding of the epidemic characteristics of HFRS and could be helpful for the prevention and control of HFRS. Currently, statistical models used to predict the incidence of HFRS, including linear regression models[10], negative binomial multivariable regression[11], and time series generalized additive models[12].
13generalized linear models (GLMs)
14autoregressive integrated moving average (ARIMA) models
15
16generalized additive models (GAMs)
17nonlinear autoregressive neural networks (NARNNs) and ARIMA (ARIMA-NARNN) models

18have been used to predict HFRS epidemics. Among those methods, the ARIMA model is the most common and useful method for modelling the temporal dependence structure of a time series. The ARIMA model can take into account changing trends, periodic changes, and random disturbances in a time series. In epidemiology, ARIMA models have been successfully used to predict the incidence of tuberculosis
18dengue
19as well as other infectious diseases

20Some studies predicted HFRS epidemics using ARIMA models and obtained a basis for targeted prevention and control measures

15
16These studies showed that ARIMA model had better predictive performance, but there was still some inconsistency between models and/or regions, which make researchers difficult to choose the appropriate one to predict HFRS epidemic. This inconsistency may be due to the fact that there are many influencing factors, such as immunization, temperature, humidity, elevation, and the local rat species
Therefore, the HFRS prediction model constructed from a particular region is not universal. To predict the epidemics of HFRS in a region accurately, a specific prediction model based on the actual data of the region need to be constructed. Previous studies indicated that some areas in Shandong Province were moderate endemic areas with HFRS incidences between 5.0/100,000 and 30.0/100,000 from 1994 to 1998. However, few studies have been conducted to explore the dynamics of HFRS occurrence and determine the potential spatiotemporal factors leading to this disease in Anqiu City. In the present study, the spatiotemporal distribution patterns of HFRS cases were explored, the key climatic drivers of HFRS transmission were identified, and the optimal ARIMA model for predicting HFRS incidences was developed for Anqiu City. The results of this study can help predict the future trends of HFRS, which can be used to more accurately prevent and control HFRS in Anqiu City.

Methods

Study area

The study area covers Anqiu City in Shandong Province, which is located in the middle of the Shandong Peninsula. Anqiu City is located between latitudes 27°51' and 28°40' north and longitudes 111°53' and 14°5' east. Anqiu City is 217 km wide and 202 km long, with a total land area of 1760 km². Anqiu City has a warm temperate continental climate influenced by the monsoon. The annual mean temperature in the study area is 12.2°C, and the average annual rainfall is 646.3 mm. Anqiu City consists of 14 towns with a total population of 0.95 million, among which the farmers account for 0.78 million. In Anqiu City, wheat, corn and peanut are the main crops, and most farmers reside less than 50 m from their farmlands. Traditional farming methods provide an opportunity for wild rodent propagation, offering suitable living conditions and sufficient food resources to increase
transmission of HFRS between rodents and from rodents to humans.

Data collection and management

HFRS cases recorded monthly in Anqiu City from 2000 to 2014 were collected from the Anqiu City Center for Disease Control and Prevention (CDC). All HFRS cases were reported to the Anqiu City CDC through the National Infectious Disease Reporting System. All HFRS cases who were first diagnosed in hospitals or clinics were verified by Anqiu City CDC. The Anqiu City population data from 2000–2014 were determined based on information from the Anqiu City Bureau of Statistics. Environmental factors for Anqiu City during the study periods, including monthly average temperature, average air pressure, average sunshine, average wind speed, monthly precipitation, and average moisture, were collected from the Anqiu City Meteorological Bureau.

Spatiotemporal analysis of HFRS case characteristics

The spatiotemporal distribution characteristics, including the temporal and spatial distribution of HFRS cases from 2000 to 2014 in Anqiu City, were analysed according to the surveillance data from the infectious disease monitoring system. All HFRS cases were coded by administrative code using ArcGIS10.2 (ESRI Inc., Redlands, CA, USA), which were matched to the town-level polygon and point layers.

Temporal trend analysis

The ARIMA model is one of the most commonly applied time series prediction model. ARIMA was designed to address highly seasonal data. There was a strong seasonality trend in this study, and we constructed ARIMA models for monthly HFRS incidences in Anqiu City from 2000 to 2014. The ARIMA model was defined as the number of autoregressive lags p, moving-average lags q and number of different passes d. The multiplicative seasonal ARIMA \((p, d, q) \times (P, D, Q)s\) model has apparent seasonal variation characteristics, which
is an extended ARIMA model. Similar to ARIMA models, the seasonal parameters include seasonal autoregressive lags $P$, seasonal moving-average lags $Q$, seasonal differences $D$, and the length of the seasonal periods. The Augmented Dickey-Fuller Unit Root (ADF) test was applied to estimate the stationarity of the time series. If the time series is not stationary, an appropriate difference can be used to make the series stationary. The Box and Jenkins strategy was used to construct the seasonal ARIMA model in this study

The ARIMA model analysis includes three main iterative steps: model identification, parameter estimation and the model evaluation. The autocorrelation functions (ACFs) and partial autocorrelation functions (PACFs) of the transformed data were utilized to determine the seasonal and non-seasonal orders and identify an appropriate ARIMA model. The conditional least squares method was applied to estimate the model parameters. In model diagnosis, white-noise-test methods were employed to check whether the residuals were independent and normally distributed. Several models may be constructed, and the selection of an optimal ARIMA model is necessary, which is usually based on the Akaike Information Criterion (AIC), normalized Bayesian Information Criterion (BIC) and Ljung-Box Q test. In addition, the mean absolute error (MAE), mean absolute percentage error (MAPE) and mean square error (MSE) were selected as the measures to evaluate the ARIMA model. The root mean square error (RMSE) was also used to access the accuracy of the models. All of these analyses were conducted using SPSS (version 17.0, SPSS, Chicago, IL, USA).

Correlation analysis between meteorological factors and HFRS incidence

Bivariate linear analysis and multiple linear analysis were used to model the relationship between meteorological factors and monthly HFRS incidence. The meteorological factors utilized in this study mainly included average temperature, monthly precipitation, average wind speed, and relative humidity.
Results

Descriptive analysis of HFRS in Anqiu City

708 cases were registered in Anqiu City during the 15-year study period. The highest average incidence rate was 15.05 per 100,000 people (in 2000), and the lowest average incidence rate was 1.15 per 100,000 people (in 2006), with an annual incidence rate of 69.20 /100,000. Among the total cases, 70.20 % were male, and 29.80 % were female, with a gender ratio (male vs. female) of 2.36. Among those patients, about 1.41 % were children under 15 years old, 6.78 % were old people over 64 years, and others were in 15-64 years group. Regarding occupation, 6.63 % were workers (including forestry farmers and builders), 6.36 % were students, and farmers accounted for 81.64 %.

The monthly HFRS cases is shown in Figure 1, which indicates that the occurrence of HFRS presented apparent seasonal character. There were two high peaks every year, the smaller epidemic occurred in spring between March and April and the larger one occurred in winter between October and November.

Spatial distribution of HFRS incidence

To account for the variations in incidence rates in small populations and areas, the annualized average incidence of HFRS per 100,000 in each town over the 15-year period was calculated. Furthermore, the annualized average incidences for each town were mapped in gradient colours. Figure 2(a-o) shows the annualized incidence for each town. Figure 2(a-o) shows that the annual incidence of HFRS gradually decreased from 2000 to 2006, and the lowest incidence of 1.15 cases per 100,000 occurred in 2006. Since 2007, the annual incidence of HFRS has increased gradually. Figure 2(p) shows the annualized average incidence for each town from 2000-2014. The annual average incidence at the town level ranged from 2.18 to 6.09 per 100 000, and among the 14 towns in Anqiu City,
Huiqu, Wushan and Xing’an had high endemic levels with incidence rates between 5.28 and 6.09 per 100,000, while Shibuzi, Shidui, Zhesan and Linghe exhibited medium endemic levels, and other towns exhibited low endemic levels (Figure2p).

**ARIMA model construction and evaluation**

**Model identification**

Monthly data of HFRS ranging from 2000 to 2013 in Anqiu City were used as the training set, and those for 2014 were used as the test data set. The sequence diagrams showed that the onset of HFRS has seasonal characteristics with a seasonal cycle every 12 months. As shown in Figure 1, the series showed that there was a non-stationary trend, so a 1st-order trend difference and a 1st-order seasonal difference were used to stabilize the average HFRS incidence. The converted series showed improved stability. Based on the distribution characteristics, we created eight models, ARIMA (0, 1, 0) (0, 1, 0)\(_{12}\), ARIMA (0, 1, 1) (0, 1, 1)\(_{12}\), ARIMA (0, 1, 2) (0, 1, 2)\(_{12}\), ARIMA (1, 1, 0) (1, 1, 0)\(_{12}\), ARIMA (1, 1, 1) (1, 1, 1)\(_{12}\), ARIMA (1, 1, 2) (1, 1, 2)\(_{12}\), ARIMA (2, 1, 0) (2, 1, 0)\(_{12}\), and ARIMA (2, 1, 1) (2, 1, 1)\(_{12}\) (Table 1).

**Parameter estimation**

According to the parameter estimation and goodness of fit test results (Table 1 and Table 2), we selected ARIMA (0, 1, 1) (0, 1, 1)\(_{12}\) model as the best one. The goodness of fit analysis indicated that there was no significant autocorrelation among residuals with different lags.

**Model testing and forecast analysis**

The monthly data in 2000–2013 was used to construct the ARIMA (0, 1, 1) (0, 1, 1)\(_{12}\) model (Table 3 and Figure 3), and the monthly data in 2014 were used to test the model. The predicted data, actual data and the 95% confidence limit for the predicted data for 2014
are shown in Table 3 and Figure 3. The predicted data didn't exactly match the observed data, but the observed data fell within the 95% confidence interval of the predicted data.

**Multiple linear analysis of meteorological factors and monthly HFRS incidence**

Bivariate linear analysis results showed that monthly mean temperature, monthly precipitation and wind speed were related to HFRS incidence. A multiple linear analysis method was further used to model the relationship between monthly HFRS incidence and meteorological factors. The results showed that monthly precipitation, average wind speed and relative humidity were important factors in HFRS incidence in Anqiu City (Table 4).

**Discussion**

Epidemiological surveillance is one of the important interventions in the prevention and control of infectious diseases. Time series analysis methods are very useful for dynamic prediction and effective control of the diseases. Our study showed that the occurrence of HFRS presented apparent seasonality and that there were two annual peaks: the smaller peak occurred in spring between March and April, and the larger peak occurred in winter between October and November. From a public health perspective, our results support the need to carry out deratization campaigns in spring and winter around Anqiu City as well as enhance population immunity by vaccination throughout the year. In addition, we applied a multiplicative seasonal ARIMA \((0, 1, 1)(0, 1, 1)_{12}\) model to analyse the HFRS surveillance data in Anqiu City, China. Based on the results above, the ARIMA \((0, 1, 1)\times(0, 1, 1)_{12}\) model is reliable with high prediction accuracy and can be used to predict the HFRS incidence in the subsequent year in Anqiu City. The prediction results suggested that the HFRS ARIMA model has strong ability to forecast and predict the incidence of HFRS in Anqiu City. Therefore, it is very important and necessary to learn about the knowledge of
HFRS forecasts, which can help health agencies to allocate health resources reasonably. Together with time series analyses, the application of GIS in our study provides a way to explicitly quantify HFRS and further determine the epidemiological characteristics accounting for the increasing disease risk. Our results showed that the potential risk areas were mainly concentrated around towns west of Anqiu City in recent years. The reason for this result may be that most towns in the west area are mountainous regions where the living environment is poor and villagers have weak health consciousness. Our study also indicated that an increase in HFRS incidence in Anqiu City was observed over the past 5 years, especially in 2012 when there was a small increase (Figure 2). This result may be due to the reconstruction and renovation of the old areas of Anqiu City in 2012, which included the renovation of a large number of houses, destroyed the rodent habitat, and made rats move frequently. These renovations also decreased the quality of the living environments of villagers and increased the chances of coming in contact with hantavirus, which further caused an increase in HFRS incidence. Based on our results, the government can allocate more health resources to high-risk areas and reduce the number of these resources used in low-risk areas to improve the effectiveness of interventions and the allocation of medical resources. Overall, both the temporal and spatial distribution patterns of HFRS in Anqiu City were studied. Disease prevention and control measures need to be strengthened in high-risk areas and during high-risk periods, which vary by month of the year.

In our study, correlation analysis and multiple linear analysis were used to further explore the relationship between environmental factors and HFRS incidence in Anqiu City. Our results showed that there was a negative association between temperature and HFRS incidence in Anqiu City, which was supported by other previous studies[...
High temperatures may limit the time available to farmers for outdoor activity and work, thereby reducing the opportunity for contact between people and field mice, which is one of the most common agricultural pests and a natural vector of hantavirus. In addition, some studies have suggested that the breeding rate of rodents is highest at temperatures of 10-25°C, which are favourable conditions for outdoor activity and work.

Anqiu City is located in a warm temperate continental monsoon climate zone, and the annual average temperature is 12.2°C. However, inconsistent findings have been reported in other studies that indicated a positive association between temperature and the incidence of HFRS.

This discrepancy might be due to different local conditions, such as different rodent compositions, different hantavirus serotypes, different environments and different climates in the study regions. Our data also indicated that precipitation was negatively associated with the incidence of HFRS; this finding is consistent with the findings of previous studies.

Abundant precipitation could have a negative impact on rodents by destroying their habitats. In addition, frequent rainfall may decrease the likelihood of rodent-to-human contact, rodent-to-rodent contact, and virus transmission due to decreased rodent activity and reduced human exposure. However, several previous studies showed inconsistent findings of a positive association between precipitation and HFRS incidence.

There is no clear explanation for such differences, which may reflect the heterogeneity in local climate conditions. Further studies should be conducted in different regions to gain a better understanding of the impact of precipitation on HFRS. In addition, a positive association was obtained between average wind speed and HFRS incidence in
our study, which was consistent with the results of a previous study[32].

The results of the multiple linear analysis showed that precipitation and wind speed were linearly related to the monthly numbers of HFRS cases and could be used to predict the number of HFRS cases in Anqiu City from 2000–2014. This study further provided practical evidence for the usefulness of correlation analysis and multiple linear regression analysis in HFRS prediction, with the optimum predictive climate variables being determined for different regions.

Some limitations of our study should be taken into account. First, we conducted a time series analysis without considering the factors that affected the occurrence of HFRS, such as animal reservoirs, human activities, farming patterns, and other socio-economic factors. Second, this study focused on only Shandong Province. Whether the model is suitable for other areas or infectious diseases needs further study.

Conclusions

In conclusion, HFRS incidence in Anqiu City demonstrated clear spatiotemporal heterogeneity from 2000-2014 and was primarily affected by meteorological elements and geographical factors. All of the above findings in our study support the use of spatiotemporal data to more accurately and effectively improve the understanding of the transmission patterns of HFRS. Our results can provide a quantitative basis to guide local control and prevention measures and have the potential to mitigate the risk and economic burden associated with HFRS. In addition, in order to more accurately predict the fluctuation of HFRS in Anqiu City in the next few years, it is necessary to construct a prediction model based on the data of continuous fluctuations in the region. Such prediction can help improve the the prevention and control of HFRS.

Tables

Table 1 Comparisons of plausible ARIMA models

| ARIMA model       | Model fit statistics | Ljung-Box Q(18) | Sig |
|-------------------|----------------------|-----------------|-----|
|                   | R-squared | RMSE | MAE | MaxAE | Normalized BIC | |
| ARIMA(0,1,0)(0,1,0)12 | -0.178     | 3.944 | 2.857 | 16.077 | 2.777       | 102.159 | 0.000       |
| ARIMA(0,1,1)(0,1,1)12 | 0.264     | 3.138 | 2.338 | 11.558 | 2.385       | 18.173 | 0.314       |
| ARIMA(0,1,2)(0,1,1)12 | 0.294     | 3.094 | 2.264 | 10.076 | 2.422       | 17.787 | 0.217       |
| ARIMA(1,1,0)(1,0,1)12 | 0.131     | 3.409 | 2.560 | 12.643 | 2.550       | 41.689 | 0.000       |
| ARIMA(1,1,1)(1,1,1)12 | 0.289     | 3.105 | 2.274 | 10.094 | 2.429       | 18.660 | 0.178       |
| ARIMA(1,1,2)(1,1,2)12 | 0.303     | 3.095 | 2.264 | 10.027 | 2.488       | 16.775 | 0.158       |
| ARIMA(2,1,0)(2,1,0)12 | 0.232     | 3.227 | 2.452 | 13.343 | 2.506       | 30.340 | 0.007       |
| ARIMA(2,1,1)(2,1,1)12 | 0.291     | 3.120 | 2.263 | 9.833  | 2.504       | 18.007 | 0.115       |

Table 2 Parameter for the final ARIMA(0,1,1)(0,1,1)12 model
Table 3 Comparison of predicted HFRS cases and actual values for Anqiu, during January-December 2014

| Month      | Cases | Actual value | Predicted value | 95% Confidence Interval | Noise Residuals |
|------------|-------|--------------|-----------------|-------------------------|-----------------|
| January    | 3.00  | 3.67         | [-2.13-9.47]    | -0.67                   |
| February   | 4.00  | 2.16         | [-3.64-7.95]    | 1.84                    |
| March      | 1.00  | 0.95         | [-4.85-6.74]    | 0.05                    |
| April      | 3.00  | 2.88         | [-4.92-6.68]    | 0.12                    |
| May        | 1.00  | 2.42         | [-3.38-8.21]    | -1.42                   |
| June       | 2.00  | 3.95         | [-1.85-9.74]    | -1.95                   |
| July       | 1.00  | 0.71         | [-5.08-6.51]    | 0.29                    |
| August     | 3.00  | 0.60         | [-5.20-6.39]    | 2.40                    |
| September  | 0.00  | 3.10         | [-2.70-8.89]    | -3.10                   |
| October    | 4.00  | 8.17         | [2.38-13.97]    | -4.17                   |
| November   | 6.00  | 7.03         | [1.24-12.83]    | -1.03                   |
| December   | 3.00  | 1.86         | [-3.94-7.65]    | 1.14                    |

Table 4 Multiple linear analysis of meteorological factors and monthly HFRS incidence

| Variable    | Unstandardized Coefficients | Standardized Coefficients | 95.0% Confidence Interval for B |
|-------------|-----------------------------|---------------------------|--------------------------------|
|             | B   | Beta | B   | Beta | t   | Sig. | Lower Bound | Upper Bound |
| Temperature | 0.001 | 0.004 | 0.024 | 0.269 | 0.788 | -0.007 | 0.009 |
| Precipitation | -0.002 | 0.001 | -0.241 | -2.603 | 0.010 | -0.003 | 0.000 |
| Wind speed  | 0.189 | 0.052 | 0.262 | 3.631 | 0.000 | 0.086 | 0.291 |
| Constant    | 0.055 | 0.138 | -    | 0.399 | 0.691 | -0.218 | 0.328 |
