Abstract. The study of formation of heavy quarkonia in relativistic heavy ion collisions provides important insight into the properties of the produced high density QCD medium. Lattice QCD studies show sequential suppression of quarkonia states with increasing temperature; which affirms that a full spectroscopy, can provide us a thermometer for the matter produced under extreme conditions in relativistic heavy ion collisions and one of the most direct probes of de-confinement. Muons from the decay of charmonium resonances are detected in ALICE Experiment in p+p and Pb+Pb collisions with a muon spectrometer, covering the forward rapidity region($2.5 < y < 4$). The analysis of the inclusive $J/\psi$ production in the first Pb+Pb data collected in the fall 2010 at a center of mass energy of $\sqrt{s_{NN}} = 2.76$ TeV is discussed. Preliminary results on the nuclear modification factor ($R_{AA}$) and the central to peripheral nuclear modification factor ($R_{CP}$) are presented.

1. Introduction

The quarkonia produced in ultra-relativistic heavy-ion collisions are considered as excellent effective probes of the strongly interacting medium and also proposed as a signature of deconfinement [1]. In such hot deconfined matter, the color screening dissolves the binding of the heavy quark anti-quark pair. This leads to the higher excited quarkonium states to dissolve at lower temperature. Studying the suppression pattern of quarkonia in AA collisions (where the plasma of deconfined quarks and gluons, the Quark-Gluon Plasma (QGP) is expected to form), along with the comparative quarkonia production in pp collisions will allow one to set an estimate of the initial temperature of the medium [1]. Extensive experimental results at SPS [2](including feeddown from other less bound resonances like $\psi'$ and $\chi_c$) and RHIC [3] of $J/\psi$ production in AA collisions clearly indicate that even the strong bound $J/\psi$ ground state is suppressed.

However at Large Hadron Collider(LHC) energies the $J/\psi$ production could be even enhanced due to the coalescence of un-correlated $c\bar{c}$ pairs in the medium which can cause a regeneration [4]. Initial state effects like modifications of the parton distribution functions in the nucleus relative to the nucleon (also known as shadowing) need to be taken in account [1]. The final state effects like nuclear absorption are expected to be practically irrelevant at LHC energies. Studying the pA collisions at LHC energies is henceforth

$\ast$debasish.das@saha.ac.in; debasish.das@cern.ch
crucial to quantify the role of initial shadowing effects. Using the Muon Spectrometer \cite{5} charm and beauty particles can be measured in the forward rapidity region via its di-muon decay. The ALICE Muon Spectrometer physics program \cite{5} is based on the measurement of heavy-flavor production in forward rapidity region (2.5 < y < 4) for pp, pA and AA collisions at LHC energies.

2. \(R_{AA}\) and \(R_{CP}\)

The first Pb+Pb collisions were delivered by LHC at a centre of mass energy \(\sqrt{s_{NN}} = 2.76\) TeV in the fall of 2010 at an un-explored regime of almost 14 times higher than top RHIC energy. The results presented here are based on sample corresponding to an integrated luminosity of 2.7 \(\mu\)b\(^{-1}\). The nuclear modification factors defined as \(R_{AA}\) or \(R_{CP}\) allow us to quantify the medium effects on J/ψ production. \(R_{AA}\) gives the devi-
lation in $J/\psi$ yields from AA collisions relative to the scaled (according to the number of binary nucleon-nucleon collisions) yields of $J/\psi$ from pp collisions. Figure 1 shows the inclusive $J/\psi$ $R_{AA}$ measured at forward rapidity ($2.5 < y < 4$) as a function of the average number of nucleons participating to the collision ($\langle N_{\text{part}} \rangle$) which has been calculated using the Glauber model. $\langle N_{\text{part}} \rangle$ has been weighted by the number of binary nucleon-nucleon collisions ($N_{\text{coll}}$) due to the bias caused by large centrality bins. This correction is small, except for the most peripheral bin where $\langle N_{\text{part}} \rangle \approx 46$ while the weighted value is 70. These results show weak centrality dependence and an integrated $R_{0}^{AA} = 0.49 \pm 0.03^{\text{(stat.)}} \pm 0.11^{\text{(syst.)}}$. Comparison with the RHIC measurements at $\sqrt{s_{\text{NN}}} = 200$ GeV [6] from the PHENIX experiment shows that the inclusive $J/\psi R_{AA}$ at 2.76 TeV in the ALICE forward rapidity region are higher than that measured at 200 GeV in the rapidity domain of $1.2 < |y| < 2.2$. However, the midrapidity values at 200 GeV (except in the most central collisions) are closer. The contribution from the B feed down to the $J/\psi$ production in our rapidity and $p_{T}$ domain has been measured and estimated to be $\approx 10\%$ in pp collisions at $\sqrt{s_{\text{NN}}} = 7$ TeV [7]. $R_{CP}$ can provide similar information based on the relative yield in central(C) and peripheral(P) collisions scaled by the mean number of binary collisions, but does not depend on the reference pp system. Figure 2 shows the ALICE forward rapidity measurements of $J/\psi R_{CP}$ results compared with the ATLAS measurements for the same centrality classes [8]. The $J/\psi$ mesons measured at forward rapidity down to $p_{T} = 0$ are less suppressed than the high-$p_{T}$ $J/\psi$ mesons at midrapidity (80% of the $J/\psi$ particles measured by ATLAS have a $p_{T}$ larger than 6.5 GeV/c).

3. Summary and Outlook

Nuclear modification factors $R_{AA}$ or $R_{CP}$ are measured in the first heavy-ion 2010 run of LHC. The inclusive $J/\psi$ production in Pb+Pb collisions at $\sqrt{s_{\text{NN}}} = 2.76$ TeV shows a notable suppression and no significant dependence on centrality. At central events, a smaller suppression has been found compared to PHENIX results at RHIC energies. The regeneration mechanism may explain these experimental results. The roles of the suppression and regeneration mechanisms could be disentangled by quantifying the initial shadowing effect with data from the forthcoming p+Pb run at LHC, planned for late 2012.
