Abstract. Moringa leaves were used as raw materials, ethanol and ammonium sulfate were used to construct a aqueous two-phase system to extract the flavonoids from Moringa leaves. The solid-liquid ratio, ethanol content, ultrasonic extraction time, and ultrasonic extraction temperature were selected as single factors, and the extraction process of flavonoids was optimized through single-factor experiments and orthogonal experiments. The optimal process was: 1:110 of solid-liquid ratio, 45 % of ethanol concentration, 15 minutes of ultrasonic extraction time, 70 °C of ultrasonic extraction temperature. Under this condition, the extraction rate of Moringa leaf flavonoids reached 8.37 %.

1 Introduction

Moringa belongs to the Moringa family. Moringa leaves contain a lot of trace elements, twenty kinds of amino acids and a variety of antioxidants, and low fat and cholesterol content. Moringa leaf powder could supply nutrition for human, has the functions of lowering blood pressure, lowering blood lipids and blood sugar, and preventing cancer and tumors. Studies have found that Moringa leaves contain a lot of flavonoids, and the flavonoids have anti-inflammatory, antioxidant, anti-aging, treatment of various acute and chronic diseases, and anti-cancer effects. They have application prospects in the fields of health care and medicine [1-3]. Extracting flavonoids by the method of aqueous two-phase system, the instruments used in the operation process are relatively simple, and the instruments and various reagents used are also cheap, so it could save money. Moreover, the conditions required for the aqueous two-phase system are mild, which could save experiment time. The most important thing is that the use of aqueous two-phase system could obtain a higher extraction rate, so the method of aqueous two-phase system is more and more applied to the fields of food and medicine research [4-5]. This study aims to explore the extraction process of Moringa leaf flavonoids by aqueous two-phase system, and the results could provide a theoretical basis application of Moringa leaf in food and medicine.

2 Experimental method

2.1 The standard curve

20 mg rutin was accurately weighed, then dissolved with 30 % ethanol and diluted into a 100 mL brown volumetric flask to prepare a standard solution of rutin with a concentration of 0.2 mg/mL. The pipette was used to accurately pipette 0 mL, 1.0 mL, 2.0 mL, 3. 0 mL, 4.0 mL and 5.0 mL standard solution to 25.0 mL colorimetric tube respectively. 0.7 mL of 5 % NaNO2 solution was added to the colorimetric tube. After the reaction for 6 minutes, 0.7 mL of 10 % Al(NO3)3 solution was added to the colorimetric tube. After reacting for 6 minutes, 10.0 mL of 1 mol/L NaOH solution was added to the colorimetric tube, then 30 % ethanol was added to make the volume, mixed thoroughly, and measured the absorbance after reacting for 15 minutes. The detection wavelength was 510 nm. The absorbance value was set as the ordinate (Y) and the concentration of the standard solution was set as the abscissa (X). The standard curve was drawn and the standard curve equation was obtained [6].

2.2 Aqueous two-phase extraction of Moringa leaf flavonoids

2.2.1 Preparation of ethanol-ammonium sulfate aqueous two-phase system. The dosage of ammonium sulfate was fixed and dissolved with a certain amount of deionized water, and the dosage of absolute ethanol was gradually changed. when the Moringa leaf powder was added to the solution, the solution could appear up and down layering and could remain stable. After that, the aqueous two-phase system was successfully established [7-12].

2.2.2 Extraction of flavonoids. 0.2 g of Moringa leaf powder was added in an Erlenmeyer flask according to the method of preparing an aqueous two-phase system, 3.0 g of anhydrous ammonium sulfate and 10. 0 mL deionized
Then water were added, shaken well. Then 10.0 mL of absolute ethanol was added, shaken well and stood still. After the solution had obvious upper and lower stratification, it indicated that the ethanol-ammonium sulfate aqueous two-phase system was successfully established. After the established ethanol-ammonium sulfate aqueous two-phase system was treated by ultrasonic at 60 °C for 10 minutes, the extract was put into a separatory funnel for static layering. After 10 minutes, the upper and lower phases of the extract were collected with a graduated cylinder and recorded the volumes respectively. Then the upper and lower two-phase extracts were put into a high-speed centrifuge, centrifuged at 3500 r/min for 10 minutes. Then, the extracts were ready for further experiment. 2.0 mL of the centrifuged upper layer extract was pipetted and added into a 25.0 mL colorimetric tube, then the content of Moringa leaf flavonoids was detected by the method of the determination of rutin standard solutions in previous.

2.3 Single factor experiments

2.3.1 The effect of solid-liquid ratio. 0.2 g of Moringa leaf powder was weighed in an Erlenmeyer flask, and the solid-liquid ratio was set as 1:100, 1:110, 1:120, 1:130, 1:140. Then, the effect of the solid-liquid ratio on the extraction rate of Moringa leaves was studied under the extraction temperature of 60 °C, the ultrasonic time of 10 minutes, and the ethanol concentration of 50%.

2.3.2 The effect of ethanol concentration. 0.2 g of Moringa leaf powder was weighed in an Erlenmeyer flask, and the ethanol concentration was set as 35%, 40%, 45%, 50% and 55%. Then, the effect of the ethanol concentration on the extraction rate of Moringa leaves was studied under the the extraction temperature of 60 °C, the ultrasonic time of 10 minutes, and the solid-liquid ratio of 1:100.

2.3.3 The effect of ultrasonic extraction time. 0.2 g of Moringa leaf powder was weighed in an Erlenmeyer flask, and the ultrasonic extraction time was set as 5 minutes, 10 min, 15 min, 20 min, 25 min. Then, the effect of the ethanol concentration on the extraction rate of Moringa oleifera leaves was studied under the the extraction temperature of 60 °C, the ethanol concentration of 50%, and the solid-liquid ratio of 1:100.

2.3.4 The effect of ultrasonic extraction temperature. 0.2 g of Moringa leaf powder was weighed in an Erlenmeyer flask, and the ultrasonic extraction temperature was set as 40 °C, 50 °C, 60 °C, 70 °C and 80 °C. Then, the effect of the ethanol concentration on the extraction rate of Moringa leaves was studied under the ultrasonic time of 10 minutes, the ethanol concentration of 50 % and the solid-liquid ratio of 1:100.

2.4 Orthogonal experiment

The appropriate factor levels were analyzed and selected based on the above single-factor test results. The L9 (3^4) orthogonal test based on the solid-liquid ratio, ethanol concentration, ultrasonic extraction time, and ultrasonic extraction temperature was designed. Then, the optimal extraction process was obtained.

3 Results

3.1 The standard curve

As shown in Figure 1, the standard curve equation was $y = 7.2036x + 0.0071$, and the Correlation coefficient was suitable, and could be used in the calculation of the concentration of flavonoids.

3.2 The effect of solid-liquid ratio on extraction rate of flavonoids

When the solid-liquid ratio was 1:110, the extraction rate of Moringa leaf flavonoids reached the maximum value (Figure 2), so the best solid-liquid ratio (m/v) used in this experiment was 1:110.
3.3 The effect of ethanol concentration on extraction rate of flavonoids

As could be seen from Figure 3, when the ethanol concentration was 40 %, the extraction rate of Moringa leaf flavonoids reached the maximum value. However, when the ethanol concentration was too high, the extraction rate decreased continuously, perhaps because anhydrous ammonium sulfate was insoluble in absolute ethanol. Therefore, 40 % was the optimal ethanol concentration used in this experiment.

3.4 The effect of ultrasonic extraction time on extraction rate of flavonoids

It could be seen from Figure 4 that when the ultrasonic extraction time was 20 minutes, the extraction rate of Moringa leaf flavonoids reached the maximum value, which might be due to the accelerated evaporation of ethanol at a temperature of 60 °C for a long time, which affected the aqueous two-phase system. When the extraction time was 25 minutes, the extraction rate began to decrease.

3.5 The effect of ultrasonic extraction temperature on extraction rate of flavonoids

As shown in Figure 5, when the ultrasonic extraction temperature was 70 °C, the extraction rate of Moringa leaf flavonoids reached the maximum value, perhaps because the temperature was too high and the ethanol volatilized and affected the aqueous two-phase system, so the extraction rate began to descend at 80 °C. Therefore, 70 °C was the best ultrasonic extraction temperature used in this experiment.

3.6 The result of orthogonal experiments

Based on the results of single factor experiments, the orthogonal experiments were carried out with solid-liquid ratio, ethanol concentration, ultrasonic extraction time and ultrasonic extraction temperature as the factors to determine the best extraction process (Table 1). The R value obtained from the orthogonal experiment results was analyzed (Table 2), that could be seen that the ethanol concentration was the most important factor, and the ultrasonic extraction temperature was the least important factor. Then, combined the K value of each factor in Table 2, the optimal extraction scheme determined in this experiment was A2B3C1D2. In order to verify whether the scheme optimized by the orthogonal experiment was the optimal, a verification experiment was performed on the scheme A2B3C1D2 to determine whether the extraction rate was the maximum value. The scheme A2B3C1D2 was subjected to the extraction experiment and the extraction rate of flavonoids was 8.37 %, which was close to the maximum extraction rate obtained in the orthogonal experiment process of 8.45 %. It can be concluded that the scheme A2B3C1D2 was the best extraction scheme. Therefore, the optimal process was: 1:110 of solid-liquid ratio, 45 % of ethanol concentration, 15 minutes of ultrasonic extraction time, 70 °C of ultrasonic extraction temperature.

| A (solid-liquid ratio (g/mL)) | B (ethanol concentration (%)) | C (extraction time (min)) | D (temperature (°C)) |
|------------------------------|-------------------------------|--------------------------|----------------------|
| 1 1:100                      | 35                            | 15                       | 60                   |
| 2 1:110                      | 40                            | 20                       | 70                   |
| 3 1:120                      | 45                            | 25                       | 80                   |
### Table 2. Results and analysis of orthogonal experiments

| entry | solid-liquid ratio (g/mL) | ethanol concentration (%) | extraction time (min) | temperature (°C) | extraction rate (%) |
|-------|---------------------------|---------------------------|-----------------------|------------------|---------------------|
| 1     | 1:100                     | 35                        | 15                    | 60               | 6.04                |
| 2     | 1:100                     | 40                        | 20                    | 70               | 6.51                |
| 3     | 1:100                     | 45                        | 25                    | 80               | 5.62                |
| 4     | 1:110                     | 35                        | 20                    | 80               | 5.78                |

### 4 Conclusion

In this research, an aqueous two-phase system was used to extract the flavonoids from Moringa leaves. By studying the effect of four factors such as solid-liquid ratio, ethanol concentration, ultrasonic extraction time, and ultrasonic extraction temperature on the extraction rate, and combining with orthogonal experiments to optimize the extraction process, the optimal extraction scheme was determined. Through a comprehensive study of the K and R values at various factor levels, the optimal extraction scheme in this experiment was obtained as A2B3C1D2, and verification experiments on this scheme showed that the extraction rate of flavonoids from Moringa leaves could reach 8.37%. Therefore, the optimal process was: 1:110 of solid-liquid ratio, 45% of ethanol concentration, 15 minutes of ultrasonic extraction time, 70 °C of ultrasonic extraction temperature.
