Abstract
We consider low-energy configurations for the Heitmann–Radin sticky discs functional, in the limit of diverging number of discs. More precisely, we renormalize the Heitmann–Radin potential by subtracting the minimal energy per particle, i.e. the so-called kissing number. For configurations whose energy scales like the perimeter, we prove a compactness result which shows the emergence of polycrystalline structures: The empirical measure converges to a set of finite perimeter, while a microscopic variable, representing the orientation of the underlying lattice, converges to a locally constant function. Whenever the limit configuration is a single crystal, i.e. it has constant orientation, we show that the $\Gamma$-limit is the anisotropic perimeter, corresponding to the Finsler metric determined by the orientation of the single crystal.

1 Introduction

Potentials that are attractive at long range and repulsive at very short range model many relevant systems and phenomena; among them, crystallization has a prominent place. A phenomenological potential with these features, particularly popular in Materials Science, is the Lennard–Jones potential. Maybe the most basic potential mimicking attractive/repulsive interactions and leading to crystallization is the one proposed by Heitmann and Radin (1980). In their model, particles are identified with sticky discs which maximize the number of their contact points without overlapping each other. More precisely, given $N$ discs in the plane, having diameter all equal to one and centred in $x_1, \ldots, x_N$, the corresponding Heitmann–Radin energy is given by

$$E(x_1, \ldots, x_N) := \frac{1}{2} \sum_{i \neq j} V(|x_j - x_i|),$$

where $V$ is the Heitmann–Radin potential defined by

$$V(r) := \begin{cases} +\infty & \text{if } r < 1, \\ -1 & \text{if } r = 1, \\ 0 & \text{if } r > 1. \end{cases}$$

In this paper, we are interested in compactness and convergence results for almost minimizers of the energy $E$, in the limit as $N \to \infty$. Before describing our approach, we recall the main results about the minimizers of the energy $E$ for finite $N$ and on their behaviour as $N \to \infty$. In the seminal paper, Heitmann and Radin (1980) prove that, for every fixed $N \in \mathbb{N}$, all the minimizers of the energy $E$ among the configurations $X = \{x_1, \ldots, x_N\}$ are subsets of an equilateral triangular lattice. Their proof of this result relies on an ansatz on the exact value of the minimal energy which was previously provided by Harborth (1974). Moreover, the authors exhibit some explicit minimizers for all number $N$ of particles, such minimizers are regular hexagons with side $s$ whenever $N = N_r = 1 + 6 + \cdots + 6s$, whereas, for general $N_s < N < N_s+1$, they are obtained by nestling the remaining discs around the boundary of the regular hexagon constructed for $N_s$. Clearly, the empirical measures associated with such minimizers converge (suitably scaled) to a macroscopic hexagon, referred to as Wulff shape. However, the minimizing configurations are in general non-unique; in De Luca and Friesecke (2017), the authors characterize, through an explicit formula, all the number of particles $N$ for which the minimizer is (up to a rotation and translation) unique.

In Au Yeung et al. (2012) it is proven that, for any sequence of minimizers, the empirical measures converge to a Wulff shape. In Schmidt (2013), a refined analysis for minimizers of the energy $E$ for $N$ particles shows that the scaling law for the fluctuation about the asymptotic Wulff shape is $C N^{3/4}$ for some $C > 0$, whereas in Davoli et al. (2017) the optimal constant $C$ is explicitly provided.

It is well known that the Wulff shape is the solution of the isoperimetric problem for a suitable anisotropic perimeter. It is then clear the link between the Heitmann–Radin energy and perimeter-like functionals. This link has been exploited in Au Yeung et al.
(2012) where it is proven that, for configurations of \( N \) particles lying on the triangular lattice and with prescribed energy upper bound scaling like a perimeter, the energy functionals \( \Gamma \)-converge, as \( N \to +\infty \), to the anisotropic perimeter of the macroscopic shape. Clearly, minimizing the \( \Gamma \)-limit with a volume constraint one obtains the Wulff shape, and this gives back that the empirical measure of minimizers converge to the Wulff shape. In De Luca and Friesecke (2018), exploiting a discrete Gauss-Bonnet formula, for finite \( N \), the energy of any configuration is rewritten in terms of a suitable discrete notion of perimeter of the graph generated by the \( N \) particles.

In this paper, we consider the asymptotic behaviour of the Heitmann–Radin energy, in the perimeter-scaling regime, without assuming that the particles lie on a reference lattice. In this respect, we prove that the Heitmann–Radin energy enforces crystallization not only for minimizers, but also for low-energy configurations. But while for minimizers the orientation of the underlying lattice is constant, for almost minimizers global orientation can be disrupted, giving rise to polycrystalline structures. Moreover, we compute the \( \Gamma \)-limit of the energy functionals whenever the limiting orientation is constant, i.e. in the case of a single crystal.

We now describe in more details our approach. Consider a configuration of \( N \) particles. We recall that, for minimizers, the particles belong to a triangular lattice, and most of them (for large \( N \)) have exactly six nearest neighbours. In this respect, the minimal energy per particle is equal to \(-6\), namely the opposite of the kissing number. Removing this bulk contribution from the energy, a surface term remains, which corresponds to the energy induced by the particles that have less than six neighbours. At a first glance, these particles can be identified as boundary particles.

In order to introduce an internal variable, representing the local orientation of the crystal lattice, we observe that, at least for minimizers, most of the particles are vertices of some equilateral triangle. To these triangles, one can easily associate some orientation, for instance through the angles between its edges and some reference straight line. Since triangular faces, edges and other geometrical objects play a role in our analysis, it is convenient to deal with the notion of discrete graph generated by the particles; in this respect, we will adopt the terminology and tools introduced in De Luca and Friesecke (2018).

To any configuration of particles, we associate an empirical measure and a piecewise constant orientation, defined on the triangular faces of the graph. We prove that, in the perimeter-scaling energy regime, the empirical measures (suitably scaled) converge—up to a subsequence—to the characteristic function of some set \( \Omega \), representing the macroscopic (poly)crystal. Moreover, the regime we deal with provides uniform bounds for the SBV norm of the function representing the microscopic orientation of the underlying lattice. In turn, we prove that the orientation converges to some limit function \( \theta \in \text{SBV}(\Omega) \), where \( \theta = \sum_{j \in J} \theta_j 1_{\omega_j} \) with \( J \subseteq \mathbb{N} \) and \( \{\omega_j\}_j \) being a Caccioppoli partition of \( \Omega \). Here each \( \omega_j \) represents a grain of the polycrystal \( \Omega \), endowed with orientation \( \theta_j \).

In the second part of the paper, we address the problem of computing the limit energy functional. We achieve this task in the case of a single crystal: if the orientation \( \theta \) is constant, then the \( \Gamma \)-limit is given by the anisotropic perimeter of \( \Omega \), where the anisotropy corresponds to a Finsler metric whose Wulff shapes are hexagons with orientation determined by \( \theta \). This result clearly agrees with that of Au Yeung et al.
(2012), the novelty being that here we do not assume that the particles belong to some reference lattice. The proof of the $\Gamma$-liminf inequality, without assuming crystallization exploits the representation formulas, introduced in De Luca and Friesecke (2018), that allow to rewrite the Heitmann–Radin energy in terms of the discrete perimeter of the graph generated by the particles.

For polycrystals, where the orientation $\theta$ is not constant, one expects some additional surface contribution, induced by grain boundaries. The sharp grain boundary energy, and in turn the $\Gamma$-limit in the general case, are not provided in this paper. Some upper and lower bounds are given in Proposition 4.1. Such bounds, although non-optimal, are enough to show that, depending on the shape of the limit set $\Omega$, both the single crystal and the polycrystal structure could be energetically favourable.

A natural question is whether our results can be extended to more general interaction potentials, which are less rigid and take into account also elastic deformations. For a discussion on richer models describing elastic interactions and leading to edge dislocations at grain boundaries, we refer to Remark 4.2. A first step in this direction would be to consider the so-called soft disc potential, for which finite crystallization results are available (Radin 1981). The crystallization problem for general potentials, both for a finite and infinite number of particles, is still an open research field which attracts much interest since decades (Blanc and Lewin 2015). For Lennard Jones type potentials, in Theil (2006) it is proven that the asymptotic energy density of minimizers is consistent with that of the regular triangular lattice. To our knowledge, our result is the first providing asymptotic (local) crystallization by compactness arguments for almost minimizers of some explicit canonical, although very simple and rigid, interaction potential.

The techniques and results developed in this paper share many analogies with the so-called tessellation problems. Among them, we recall the classical honeycomb problem, which consists in finding optimal clusters with minimal perimeter under volume constraints. Hexagonal tessellation is known to be optimal in the flat torus, thanks to the celebrated work of Hales (2001). A more quantitative analysis of this result is developed in Caroccia and Maggi (2016).

In fact, our analysis also suggests new basic tessellation problems in $\Gamma$-convergence. A prototypical example is briefly described and analysed in “Appendix”, while further generalizations could deserve further investigations.

## 2 Description of the Problem

In this section, we introduce the notation we will use in the paper.

### 2.1 The Energy Functionals

For every $\varepsilon > 0$ let $V_\varepsilon : [0, +\infty) \rightarrow [0, +\infty]$ be the Heitmann–Radin sticky disc potential (Heitmann and Radin 1980) defined by
\[ V_\varepsilon(r) := \begin{cases} +\infty & \text{if } r < \varepsilon, \\ -1 & \text{if } r = \varepsilon, \\ 0 & \text{if } r > \varepsilon. \end{cases} \]

Given \( X := \{x_1, \ldots, x_N\} \) a finite subset of \( \mathbb{R}^2 \), the Heitmann–Radin energy of \( X \) is defined by

\[ E_\varepsilon(X) := \frac{1}{2} \sum_{i \neq j} V_\varepsilon(|x_j - x_i|). \]

Let \( \mathcal{M} \) denote the class of Radon measures in \( \mathbb{R}^2 \) and let \( \mathcal{A} \) be the class of empirical measures defined by

\[ \mathcal{A} := \left\{ \mu \in \mathcal{M} : \mu = \sum_{i=1}^N \delta_{x_i}, N \in \mathbb{N}, x_i \neq x_j \text{ for } i \neq j \right\}. \]

Note that there is a one-to-one correspondence \( \mathcal{I} \) from \( \mathcal{A} \) to the class of finite subsets of \( \mathbb{R}^2 \). In view of this identification, we can define the Heitmann–Radin energies on measures by introducing the functionals \( \mathcal{E}_\varepsilon : \mathcal{M} \to [0, \infty] \) given by

\[ \mathcal{E}_\varepsilon(\mu) = \begin{cases} E_\varepsilon(\mathcal{I}(\mu)) & \text{if } \mu \in \mathcal{A}, \\ +\infty & \text{elsewhere}. \end{cases} \quad (2.1) \]

### 2.2 Discrete Graph Representation

Let \( \mu = \sum_{i=1}^N \delta_{x_i} \in \mathcal{A} \) be such that \( \mathcal{E}_\varepsilon(\mu) < +\infty \) and set \( X = \mathcal{I}(\mu) \). We say that \( x_i \) and \( x_j \) in \( X \) are linked by an edge, or bond, if their mutual distance equals to \( \varepsilon \) and we write \( \{x_i, x_j\} \) for denoting such bond. We call \( \text{Ed}_\varepsilon(X) \) the set of the bonds of \( X \) and \( (X, \text{Ed}_\varepsilon(X)) \) the bond graph of the configuration (Fig. 1).

![Fig. 1 Particle configuration and bond graph](image-url)
Since $\mathcal{E}_\varepsilon (\mu) < +\infty$, simple geometric considerations easily imply that the bond graph is a planar graph, i.e. for any two different edges $\{x, y\}$ and $\{x', y'\}$, the corresponding line segments $[x, y]$ and $[x', y']$ do not cross.

We now introduce some notation. We first provide the notion of face as it is introduced in De Luca and Friesecke (2018). By a face $f$ we mean any open and bounded subset of $\mathbb{R}^2$ which is non-empty, does not contain any point $x \in X$, and whose boundary is given by a cycle, i.e. $\partial f = \bigcup_{i=1}^k [x_{i-1}, x_i]$ for some points $x_0, x_1, \ldots, x_k = x_0 \in X$ with $\{x_{i-1}, x_i\} \in \mathcal{E}_\varepsilon (X)$. Notice that the points $x_0, \ldots, x_{k-1}$ do not need to be pairwise distinct, as a face might contain “inner wire edges” (see the definition below). We denote by $F_\varepsilon (X)$ the set of faces of the bond graph $(X, \mathcal{E}_\varepsilon (X))$. We notice also that our definition differs from standard conventions for planar graphs (see for instance Bollobás 1998) since, in graph theory, a face is a connected open (not necessarily bounded) subset of $\mathbb{R}^2$ not intersecting $X$ and $\mathcal{E}_\varepsilon (X)$, and whose boundary is given by a union of edges (which do not necessarily form a unique cycle). We denote by $\mathcal{F}_\varepsilon (X)$ the set of such “standard faces” of the graph $(X, \mathcal{E}_\varepsilon (X))$, so that we have that $\mathcal{F}_\varepsilon (X) = F_\varepsilon (X) \cup R_\varepsilon (X)$ where $R_\varepsilon (X)$ is the set of the standard faces whose boundary is not given by a unique cycle plus the unbounded face. Moreover, we define $F_\varepsilon (X)$ as the set of faces $f \in F_\varepsilon (X)$ for which $k = 3$ and $F_\varepsilon (X) : = F_\varepsilon (X) \setminus F_\varepsilon (X)$.

Set $v_0 (X) := +X, v_1 (X) := +\mathcal{E}_\varepsilon (X)$, and $v_2 (X) := +F_\varepsilon (X)$, we define the Euler characteristic of the graph $(X, \mathcal{E}_\varepsilon (X))$ as

$$\chi (X) := \sum_{k=0}^{2} (-1)^k v_k (X). \quad (2.2)$$

Notice that

$$\chi (X) \geq 1 \quad \text{for every } X. \quad (2.3)$$

Indeed, by Euler’s formula (see, e.g. Bollobás 1998), we get

$$1 = +X - +\mathcal{E}_\varepsilon (X) + +\mathcal{F}_\varepsilon (X) - +\text{Conn}_\varepsilon (X) + X$$

$$- +\mathcal{E}_\varepsilon (X) + +F_\varepsilon (X) + +R_\varepsilon (X) - +\text{Conn}_\varepsilon (X) = \chi (X)$$

$$+ +R_\varepsilon (X) - +\text{Conn}_\varepsilon (X),$$

being $\text{Conn}_\varepsilon (X)$ the set of connected components of $(X, \mathcal{E}_\varepsilon (X))$. By construction, it is easy to check that $+\text{Conn}_\varepsilon (X) - +R_\varepsilon (X) \geq 0$, so that (2.3) holds true.

We now denote by $\mathcal{E}_\varepsilon,\text{ow}(X)$ the set of the outer wire edges, namely of the edges that do not lie on the boundary of any face and by $\mathcal{E}_\varepsilon,\text{iw}(X)$ the set of the inner wire edges, namely of the edges lying on the boundary of precisely one face but not on the boundary of its closure; moreover we set $\text{Wire}(X) := \mathcal{E}_\varepsilon,\text{ow}(X) \cup \mathcal{E}_\varepsilon,\text{iw}(X)$.

By De Luca and Friesecke (2018, Eqs (3.7), (2.4), (3.4) and Subsection 2.6), applied with $V = V_\varepsilon$, we have that

$$E_\varepsilon (X) + 3 +X = \frac{1}{\varepsilon} \text{Per} \left( \bigcup_{f \in F_\varepsilon (X)} f \right) + 2 +\mathcal{E}_\varepsilon,\text{ow}(X)$$
\[ + \sum_{f \in F^\Delta_\varepsilon(X)} \left( \frac{\text{Per}(f)}{\varepsilon} + 2\varepsilon \text{Ed}_{\varepsilon,w}(f) - 3 \right) + 3 \chi(X), \]

where $\text{Per}(A)$ denotes the De Giorgi’s perimeter of $A$ for every measurable set $A$ and $\text{Ed}_{\varepsilon,w}(f)$ denotes the set of the inner wire edges lying on the boundary of $f$. Since \( \sum_{f \in F^\Delta_\varepsilon(X)} \# Ed_{\varepsilon,w}(f) = \# Ed_{\varepsilon,w}(X) \), we deduce that

\[ E_\varepsilon(X) + 3\varepsilon X = \frac{1}{\varepsilon} \text{Per} \left( \bigcup_{f \in F_\varepsilon(X)} f \right) + \sum_{f \in F^\Delta_\varepsilon(X)} \left( \frac{\text{Per}(f)}{\varepsilon} - 3 \right) + 2\varepsilon \text{Wire}(X) + 3\chi(X). \]  

(2.4)

With a little abuse of notation, we will often write $\text{Ed}_\varepsilon(\mu)$, $F_\varepsilon(\mu)$, $F^\Delta_\varepsilon(\mu)$ and $F^{\Delta_\varepsilon}_{\neq}(\mu)$ in place of $\text{Ed}_\varepsilon(I(\mu))$, $F_\varepsilon(I(\mu))$, $F^\Delta_\varepsilon(I(\mu))$ and $F^{\Delta_\varepsilon}_{\neq}(I(\mu))$, respectively.

### 2.3 Grain Orientations

Let $\mu \in \mathcal{A}$ be such that $E_\varepsilon(\mu) < +\infty$. For every $\alpha \in \mathbb{R}$, we define

\[ P(\alpha) := \arg \min \left\{ \left| \alpha - k \frac{\pi}{3} \right| : k \in \mathbb{Z} \right\} \in \mathbb{Z}, \]

with the convention that, if the argmin is not unique, then we choose the minimal one. Clearly,

\[ P \left( \alpha + j \frac{\pi}{3} \right) = P(\alpha) + j \quad \text{for every} \quad j \in \mathbb{Z}. \]  

(2.5)

Let $f \in F^\Delta_\varepsilon(\mu)$ and let $w = e^{i\alpha_w}$ be a unit vector parallel to one of the edges of $f$ (with arbitrary orientation). We set

\[ \alpha(f) := \alpha_w - P(\alpha_w) \frac{\pi}{3}, \quad \theta(f) := \alpha(f) + \frac{\pi}{2}. \]  

(2.6)

Since all the edges of an equilateral triangle are obtained by rotating one fixed edge by an integer multiple of $\frac{\pi}{3}$, in view of (2.5), the definitions of $\alpha(f)$ and $\theta(f)$ in (2.6) are well-posed. Note also that $\theta(f)$ is the angle between $e_1$ and one of the medians of $f$. Moreover, by construction, $\alpha(f) \in (-\frac{\pi}{6}, \frac{\pi}{6})$ and hence $\theta(f) \in (\frac{\pi}{3}, \frac{2}{3}\pi]$.

We set

\[ \theta_\varepsilon(\mu) := \sum_{f \in F^\Delta_\varepsilon(\mu)} \theta(f) \mathbb{1}_f. \]  

(2.7)
2.4 Surface Energy and Wulff Shape

Let us introduce a Finsler norm \( \varphi \) whose unit ball is a unitary hexagon in \( \mathbb{R}^2 \). For every \( \eta \in \mathbb{R}^2 \) set

\[
\varphi(\eta) := \min \left\{ \sum_{j=1}^{3} |\lambda_j| : \eta = \sum_{j=1}^{3} \lambda_j v_j, \lambda_j \in \mathbb{R} \right\},
\]

where

\[
v_1 = e^{i \frac{\pi}{6}}, \quad v_2 = e^{i \frac{\pi}{2}}, \quad v_3 = e^{i \frac{5}{6} \pi}.
\]

(2.8)

We define a one-parameter family of Finsler norms \( \varphi_\theta \), for \( \theta \in (\frac{\pi}{3}, \frac{2}{3} \pi] \) by setting

\[
\varphi_\theta(\eta) := \min \left\{ \sum_{j=1}^{3} |\lambda_j| : \eta = \sum_{j=1}^{3} \lambda_j v_{j, \theta}, \lambda_j \in \mathbb{R} \right\},
\]

where \( v_{j, \theta} = e^{i(\theta - \frac{\pi}{2})} v_j \) for \( j = 1, 2, 3 \). Note that \( \varphi_{\frac{\pi}{2}} \equiv \varphi \).

(2.9)

For every set \( G \) of finite perimeter, we set

\[
\text{Per}_{\varphi_\theta}(G) := \int_{\partial^* G} \varphi_\theta(\nu) \, d\mathcal{H}^1,
\]

where \( \nu \) denotes the outer normal to \( \partial^* G \) and \( \mathcal{H}^1 \) denotes the one dimensional Hausdorff measure.

We denote by \( W \) the regular hexagon centred at the origin with area equal to one, defined by

\[
W := \left\{ x \in \mathbb{R}^2 : |x \cdot v_i| \leq 2^{-\frac{1}{2}} 3^{-\frac{1}{4}}, \ i = 1, 2, 3 \right\},
\]

and set \( W_\theta := e^{i \theta} W \) for all \( \theta \in \mathbb{R} \). These sets are referred to as Wulff shapes: it is well known (Fonseca and Müller 1991) that they are the solutions of the isoperimetric inequality corresponding to the anisotropic perimeters \( \varphi_\theta \).

2.5 Preliminaries on SBV Functions

We refer to the book (Ambrosio et al. 2000) for the definitions and the main properties of BV and SBV functions, sets of finite perimeter, and Caccioppoli partitions. Here we list few preliminaries and properties that will be useful in the following. We begin by recalling some standard notation.

Let \( A \subseteq \mathbb{R}^2 \) be open. As customary, \( \text{BV}(A) \) (resp. \( \text{SBV}(A) \)) denotes the set of functions of bounded variation (resp. special functions of bounded variation) defined on \( A \) and taking values in \( \mathbb{R} \). Moreover, \( \text{SBV}_{\text{loc}}(A) \) denotes the class of functions belonging to \( \text{SBV}(A') \) for all open bounded sets \( A' \subset\subset A \). Given any set \( D \subset \mathbb{R} \), the classes of functions \( \text{BV}(A; D), \text{SBV}(A; D) \) and \( \text{SBV}_{\text{loc}}(A; D) \) are defined in the obvious way.

\( \square \) Springer
We say that a set $\Omega \subset \mathbb{R}^2$ has finite perimeter in $A$ if $1_{\Omega} \in BV(A)$ and we denote by $\text{Per}(\Omega, A)$ the relative perimeter of $\Omega$ in $A$. It is well known that $\text{Per}(\Omega, A) = \mathcal{H}^1(\partial^* \Omega \cap A)$, where $\partial^*$ denotes the reduced boundary. If $A = \mathbb{R}^2$ we simply say that $\Omega$ has finite perimeter and we denote by $\text{Per}(\Omega)$ its perimeter. Finally, if $\Omega$ is a set of finite perimeter, a Caccioppoli partition of $\Omega$ is a countable partition $\{\omega_j\}_j$ of $\Omega$ into sets of (positive Lebesgue measure and) finite perimeter with $\sum_j \text{Per}(\omega_j, \Omega) < \infty$.

We recall that the distributional gradient $Dg$ of a function $g \in SBV(A)$ can be decomposed as:

$$Dg = \nabla g \mathcal{L}^2 \llcorner A + (g^+ - g^-) \otimes \nu_g \mathcal{H}^1 \llcorner S_g,$$

where $\nabla g$ is the approximate gradient of $g$, $S_g$ is the jump set of $g$, $\nu_g$ is a unit normal to $S_g$ and $g^\pm$ are the approximate trace values of $g$ on $S_g$.

We recall a compactness result.

**Theorem 2.1** [Compactness Ambrosio (1990)]. Let $A$ be bounded and let $\{gh\} \subset SBV(A)$. Assume that there exists $p > 1$ and $C > 0$ such that

$$\int_A |\nabla g_h|^p \, dx + \mathcal{H}^1(S_{g_h}) + \|g_h\|_{L^\infty(A)} \leq C \quad \text{for all } h \in \mathbb{N}. \quad (2.11)$$

Then, there exists $g \in SBV(A)$ such that, up to a subsequence,

$$g_h \rightarrow g \text{ (strongly) in } L^1(A),$$

$$\nabla g_h \rightharpoonup \nabla g \text{ (weakly) in } L^1(A; \mathbb{R}^2),$$

$$\liminf_{h \to \infty} \mathcal{H}^1(S_{g_h} \cap A') \geq \mathcal{H}^1(S_g \cap A') \text{ for every open set } A' \subset A. \quad (2.12)$$

In the following, we say that a sequence $\{g_h\} \subset SBV(A)$ weakly converges in $SBV(A)$ to a function $g \in SBV(A)$, and we write that $g_h \rightharpoonup g$ in $SBV(A)$, if $g_h$ satisfy (2.11) for some $p > 1$ and $g_h \rightarrow g$ in $L^1(A)$. The corollary below easily follows by Theorem 2.1.

**Corollary 2.2** Let $\{g_h\} \subset SBV(\mathbb{R}^2)$. Assume that there exists $p > 1$ and $C > 0$ such that

$$\int_{\mathbb{R}^2} |\nabla g_h|^p \, dx + \mathcal{H}^1(S_{g_h}) + \|g_h\|_{L^\infty(\mathbb{R}^2)} \leq C \quad \text{for all } h \in \mathbb{N}. \quad (2.13)$$

Then, there exists $g \in SBV(\mathbb{R}^2)$ such that, up to a subsequence, (2.12) holds for every open bounded set $A \subset \mathbb{R}^2$.

We say that $\{g_h\} \subset SBV_{\text{loc}}(\mathbb{R}^2)$ weakly converges in $SBV_{\text{loc}}(\mathbb{R}^2)$ to a function $g \in SBV_{\text{loc}}(\mathbb{R}^2)$, and we write that $g_h \rightharpoonup g$ in $SBV_{\text{loc}}(\mathbb{R}^2)$, if $g_h \rightarrow g$ in $SBV(A)$ for every open bounded set $A$.
3 $\Gamma$-Convergence Analysis

In this section, we study the asymptotic behaviour, as $\varepsilon \to 0$, of the functionals $E_{\varepsilon}$ defined in (2.1). As mentioned in the introduction, we first normalize the energy $E_{\varepsilon}(\mu)$ subtracting the bulk term $3\mu(\mathbb{R}^2)$, and then study the normalized functional in the perimeter scaling. Summarizing, we consider the functionals $\varepsilon(E_{\varepsilon}(\mu) + 3\mu(\mathbb{R}^2))$ and provide a compactness and a $\Gamma$-convergence result.

3.1 Compactness

Theorem 3.1 Let $\{\mu_\varepsilon\} \subset \mathcal{M}$ be such that $E_{\varepsilon}(\mu_\varepsilon) + 3\mu_\varepsilon(\mathbb{R}^2) \leq C_\varepsilon$ for some $C \in \mathbb{R}$. Then, up to a subsequence,

(i) $\varepsilon^{3/2} \mu_\varepsilon \rightharpoonup 1_{\Omega} \text{d}x$ for some set $\Omega \subset \mathbb{R}^2$ with $1_\Omega \in BV(\mathbb{R}^2)$;
(ii) $\theta_\varepsilon(\mu_\varepsilon) \rightharpoonup \theta$ in $SBV_{\text{loc}}(\mathbb{R}^2)$, for some $\theta = \sum_{j \in J} \theta_j 1_{\omega_j}$ in $SBV(\mathbb{R}^2)$, where $J \subseteq \mathbb{N}$, $\{\omega_j\}_j$ is a Caccioppoli partition of $\Omega$, and $\{\theta_j\}_j \subset (\frac{\pi}{6}, \frac{2}{3}\pi]$.

Proof The proof is divided into two steps.

Step 1 We first prove that (ii) holds true for some set $\Omega$ with finite perimeter. In view of the energy bound, (2.4), and (2.3), we have

$$C \geq \varepsilon \left( E_{\varepsilon}(\mu_\varepsilon) + 3\mu_\varepsilon(\mathbb{R}^2) \right) \geq \text{Per} \left( \bigcup_{f \in F_\varepsilon(\mu_\varepsilon)} f \right) + \frac{1}{4} \sum_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} \text{Per}(f)$$

$$\geq \frac{1}{4} \text{Per} \left( \bigcup_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} f \right) = \frac{1}{4} \text{Per}(\Omega_\varepsilon),$$

where we have set $\Omega_\varepsilon := \bigcup_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} f$. Then, the claim (ii) follows by the compactness statement (a) of Theorem A.2.

Step 2 Now we prove (i) with $\Omega$ provided in Step 1. To this purpose, for every $f \in F_\varepsilon^\Delta(\mu_\varepsilon)$ we denote by $a_j(f)$ ($j = 1, 2, 3$) the vertices of $f$, and we define

$$\hat{\mu}_\varepsilon := \frac{1}{6} \sum_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} \sum_{j=1}^3 \delta_{a_j(f)}, \quad \tilde{\mu}_\varepsilon := \sum_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} 1_f \text{d}x. \quad (3.1)$$

By the energy bound and (2.4),

$$C \geq \varepsilon(E_{\varepsilon}(\mu_\varepsilon) + 3\mu_\varepsilon(\mathbb{R}^2)) \geq \text{Per} \left( \bigcup_{f \in F_\varepsilon(\mu_\varepsilon)} f \right)$$
so that, by the isoperimetric inequality, we obtain

\[ \tilde{\mu}_\varepsilon(\mathbb{R}^2) = |\Omega_\varepsilon| \leq \left| \bigcup_{f \in F_\varepsilon(\mu_\varepsilon)} f \right| \leq C. \]

By the proof of Step 1, it follows that, up to a subsequence, \( \sum_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} \mathbb{1}_f \to 1_{\Omega} \) in \( L^1(\mathbb{R}^2) \).

We now show that \( \varepsilon^2 \sqrt{3} \tilde{\mu}_\varepsilon - \bar{\mu}_\varepsilon \to 0 \). Let \( \psi \in C_c^0(\mathbb{R}^2) \), and let \( \psi_f \) be the average of \( \psi \) on the triangle \( f \in F_\varepsilon^\Delta(\mu_\varepsilon) \). Then,

\[
\left| \left\langle \varepsilon^2 \frac{\sqrt{3}}{2} \tilde{\mu}_\varepsilon - \bar{\mu}_\varepsilon, \psi \right\rangle \right| = \left| \sum_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} \left\langle \varepsilon^2 \frac{\sqrt{3}}{2} \tilde{\mu}_\varepsilon - \bar{\mu}_\varepsilon, \psi \mathbb{1}_f \right\rangle \right| 
\leq \sum_{f \in F_\varepsilon^\Delta(\mu_\varepsilon)} \left| \left\langle \varepsilon^2 \frac{\sqrt{3}}{2} \tilde{\mu}_\varepsilon - \bar{\mu}_\varepsilon, (\psi - \psi_f) \mathbb{1}_f \right\rangle \right| 
\leq 2 |\tilde{\mu}_\varepsilon|(\mathbb{R}^2) r_\varepsilon(\psi) \leq C r_\varepsilon(\psi) \to 0,
\]

where \( r_\varepsilon(\psi) \) is the modulus of continuity of \( \psi \).

Now we prove that \( \varepsilon^2 |\mu_\varepsilon - \tilde{\mu}_\varepsilon|(\mathbb{R}^2) \to 0 \). We first notice that

\[ \sharp Y_\varepsilon \leq 2 \varepsilon (E_\varepsilon(\mu_\varepsilon) + 3 \mu(\mathbb{R}^2)) , \]

where \( Y_\varepsilon := \{ x \in \text{supp } \mu_\varepsilon : x \text{ lies on at most five bonds} \} \). As a consequence, by using the energy bound, we get

\[ \varepsilon^2 |\mu_\varepsilon - \tilde{\mu}_\varepsilon|(\mathbb{R}^2) = \varepsilon^2 (\mu_\varepsilon - \tilde{\mu}_\varepsilon)(\mathbb{R}^2) \leq \varepsilon^2 \sharp(\text{supp } \mu_\varepsilon \setminus \text{supp } \tilde{\mu}_\varepsilon) = \varepsilon^2 \sharp Y_\varepsilon \leq C \varepsilon \to 0. \]

By combining (3.2) and (3.3) we obtain (i).

\[ \square \]

### 3.2 \( \Gamma \)-Convergence

This section is devoted to the proof of the main \( \Gamma \)-convergence result for the energy functionals \( E_\varepsilon(\mu) + 3 \mu(\mathbb{R}^2) \), under the assumption that the limit orientation is unique.

**Theorem 3.2** The following \( \Gamma \)-convergence result holds true.

(i) (\( \Gamma \)-liminf inequality) Let \( \{ \mu_\varepsilon \} \subset \mathcal{M} \) satisfy (i) and (ii) of Theorem 3.1 with \( \theta = \bar{\theta} \mathbb{1}_\Omega \) for some \( \bar{\theta} \in (\pi/3, 2\pi/3) \). Then

\[
\liminf_{\varepsilon \to 0} \varepsilon \left( E_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2) \right) \geq \text{Per}_{\bar{\theta}}(\Omega). \quad (3.4)
\]
(ii) \((\Gamma\text{-limsup inequality})\) For every set \(\Omega \subset \mathbb{R}^2\) of finite perimeter and for every \(\overline{\theta} \in (\frac{\pi}{4}, \frac{2}{3}\pi]\), there exists a sequence \(\{\mu_\varepsilon\} \subset \mathcal{M}\) satisfying (i) and (ii) of Theorem 3.1 with \(\theta = \overline{\theta} \mathbb{I}_\Omega\) such that

\[
\limsup_{\varepsilon \to 0} \varepsilon \left( E_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2) \right) \leq \text{Per}_{\varphi_0}(\Omega). \quad (3.5)
\]

Before providing the rigorous lower bounds leading to the proof of (3.4), we briefly discuss the main idea in an informal language. Looking at (2.4), neglecting the “−3” and the positive terms \(2\varphi\text{Wire}(-\cdot) + 3\chi(-\cdot)\), the formula would reduce to the perimeter of the union of triangular faces. In turn, the \(\Gamma\)-liminf inequality would be nothing but the lower semicontinuity of the corresponding crystalline perimeter. The main effort in the proof of (i) will be to deal with the negative \(-3\) contribution coming from non-triangular faces. We stress that this term provides a real energy gain at grain boundaries, where the energy density is in general lower than the sum of the perimeter of two touching grains. As a matter of fact, we will prove that non-triangular faces cannot decrease the energy density for single crystals in the limit as \(\varepsilon \to 0\).

**Proof of (i)** We can assume without loss of generality that there exists \(C \in \mathbb{R}\) such that

\[
\sup_{\varepsilon > 0} \varepsilon (E_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \leq C. \quad (3.6)
\]

\(\square\)

**Notation 1** For every \(\varepsilon > 0\) set

\[
G_\varepsilon := \bigcup_{f \in F_\varepsilon(\mu_\varepsilon)} f \quad \text{and} \quad \Omega_\varepsilon := \bigcup_{f \in F^\Delta_\varepsilon(\mu_\varepsilon)} f. \quad (3.7)
\]

We classify the faces \(F^\Delta_{\varepsilon}(\mu_\varepsilon)\) into two subclasses given by the faces having “small” and “large” perimeter, respectively. To this end, we introduce a parameter \(\delta \in (0, \frac{1}{4})\) and we set:

\[
S^\Delta_{\varepsilon,\delta} := \left\{ f \in F^\Delta_{\varepsilon}(\mu_\varepsilon) : \text{Per}(f) < \frac{\varepsilon}{\delta} \right\} \quad \text{and} \quad L^\Delta_{\varepsilon,\delta} := \left\{ f \in F^\Delta_{\varepsilon}(\mu_\varepsilon) : \text{Per}(f) \geq \frac{\varepsilon}{\delta} \right\}. \quad (3.8)
\]

Set moreover

\[
\Sigma_{\varepsilon,\delta} := \bigcup_{f \in S^\Delta_{\varepsilon,\delta}} f, \quad \Lambda_{\varepsilon,\delta} := \bigcup_{f \in L^\Delta_{\varepsilon,\delta}} f, \quad \text{and} \quad O_{\varepsilon,\delta} := \Omega_\varepsilon \cup \Sigma_{\varepsilon,\delta}. \quad (3.9)
\]

By construction \(G_\varepsilon = \Omega_\varepsilon \cup \Sigma_{\varepsilon,\delta} \cup \Lambda_{\varepsilon,\delta} = O_{\varepsilon,\delta} \cup \Lambda_{\varepsilon,\delta}\), where the unions are all disjoint, so that

\[
\text{Per}(O_{\varepsilon,\delta}) \leq \text{Per}(G_\varepsilon) + \sum_{f \in L^\Delta_{\varepsilon,\delta}} \text{Per}(f). \quad (3.10)
\]
Claim 1 $\varepsilon(E(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \geq \text{Per}(O_{\varepsilon, \delta}) + \sum_{f \in S^{\not=\Delta}_{\varepsilon, \delta}} (\text{Per}(f) - 3\varepsilon) + r(\delta)$, where $r(\delta) \to 0$ as $\delta \to 0$.

Indeed, by (2.3), (3.6) and (2.4), we have

$$C \geq \sum_{f \in L^{\not=\Delta}_{\varepsilon, \delta}} (\text{Per}(f) - 3\varepsilon) \geq \varepsilon \left( \frac{1}{\delta} - 3 \right) \# L^{\not=\Delta}_{\varepsilon, \delta}. \quad (3.11)$$

Therefore, by (2.4), (3.10) and (3.11), it follows that

$$\varepsilon(E(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \geq \text{Per}(G_{\varepsilon}) + \sum_{f \in F^{\not=\Delta}_{\varepsilon, \delta}} (\text{Per}(f) - 3\varepsilon) \geq \text{Per}(O_{\varepsilon, \delta}) + \sum_{f \in S^{\not=\Delta}_{\varepsilon, \delta}} (\text{Per}(f) - 3\varepsilon) - 3\varepsilon \# L^{\not=\Delta}_{\varepsilon, \delta} \quad (3.12)$$

which proves the claim with $r(\delta) := \frac{3C\delta}{1-3\delta}$.

Notation 2 We now split the family of triangular faces into two types: the faces that are “almost aligned” with the limit orientation $\tilde{\theta}$, and all the remaining ones. To this end, we introduce a parameter $\eta \in (0, \frac{\pi}{6})$ and we set:

$$\Omega_{\eta}^{\varepsilon} := \bigcup_{f \in F^{\Delta}_{\varepsilon, \delta}(\mu_\varepsilon)} f \quad \text{and} \quad \Omega_{\eta}^{\varepsilon+} := \bigcup_{f \in F^{\Delta}_{\varepsilon, \delta}(\mu_\varepsilon)} f.$$

We add to $\Omega_{\eta}^{\varepsilon+}$ all its adjacent non-triangular faces with small perimeter, by setting

$$I_{\eta, \delta} := \{ f \in S^{\not=\Delta}_{\varepsilon, \delta} : \mathcal{H}^1(\partial f \cap \partial \Omega_{\eta}^{\varepsilon+}) \geq \varepsilon \}, \quad \Omega_{\eta}^{\varepsilon+} := \Omega_{\eta}^{\varepsilon+} \cup \bigcup_{f \in I_{\eta, \delta}} f.$$

For every connected component $\gamma$ of (the closure of) $\Omega_{\eta}^{\varepsilon+}$, we define $\partial_{\eta, \delta}^{\varepsilon+}(\gamma)$ as the set of bonds lying both on the boundary of $\gamma$ and on the boundary of $O_{\varepsilon, \delta}$ and by $B_{\eta, \delta}^{\varepsilon+}(\gamma)$ as the set of bonds lying only on the boundary of $\gamma$ but not on that of $O_{\varepsilon, \delta}$, namely

$$\partial_{\eta, \delta}^{\varepsilon+}(\gamma) := \{ (x, y) \in E_{\varepsilon}(\mu_\varepsilon) : [x, y] \subset \partial \gamma \cap \partial O_{\varepsilon, \delta} \}, \quad B_{\eta, \delta}^{\varepsilon+}(\gamma) := \{ (x, y) \in E_{\varepsilon}(\mu_\varepsilon) : [x, y] \subset \partial \gamma \setminus \partial O_{\varepsilon, \delta} \}. \quad (3.13)$$

With (3.13) in hand, we can classify the connected components of $O_{\varepsilon, \delta}$ into two families: the ones for which the “outer perimeter” is larger than the “inner perimeter” and viceversa.
More precisely, we call \( \zeta_1, \ldots, \zeta_{K_{\eta, \delta}} \) the connected components of \( \tilde{\Omega}^{\eta, +}_{\varepsilon, \delta} \) such that

\[
\sharp \partial^{\eta, +}_{\varepsilon, \delta} (\zeta_k) \geq \sharp \partial^{\eta, +}_{\varepsilon, \delta} (\zeta_k),
\]

and we set

\[
\hat{O}^{\eta}_{\varepsilon, \delta} := O^{\varepsilon, \delta} \setminus \bigcup_{k=1}^{K_{\eta, \delta}} \zeta_k.
\]

Finally, \( \xi_1, \ldots, \xi_{J_{\eta, \delta}} \) denote the connected components of \( \tilde{\Omega}^{\eta, +}_{\varepsilon, \delta} \) such that

\[
1 \leq \sharp \partial^{\eta, +}_{\varepsilon, \delta} (\xi_j) < \sharp \partial^{\eta, +}_{\varepsilon, \delta} (\xi_j).
\]

Note that, by construction, the sets \( \partial^{\eta, +}_{\varepsilon, \delta} (\xi_j) \) and \( \partial^{\eta, +}_{\varepsilon, \delta} (\xi_j) \) do not change if in (3.13) we replace \( O^{\varepsilon, \delta} \) by \( \hat{O}^{\eta}_{\varepsilon, \delta} \) (Fig. 2).

**Claim 2** \( \text{Per}(O^{\varepsilon, \delta}) \geq \text{Per}(\hat{O}^{\eta}_{\varepsilon, \delta}). \)

Indeed, in view of (3.14),

\[
\text{Per}(O^{\varepsilon, \delta}) = \text{Per}(\hat{O}^{\eta}_{\varepsilon, \delta}) + \sum_{k=1}^{K_{\eta, \delta}} (\text{Per}(\zeta_k) - 2\varepsilon \cdot \partial^{\eta, +}_{\varepsilon, \delta} (\zeta_k)) \geq \text{Per}(\hat{O}^{\eta}_{\varepsilon, \delta}).
\]

**Notation 3** Set

\[
B^{\eta, -}_{\varepsilon, \delta} := \left\{ x, y \in \text{Ed}_\varepsilon(\mu_\varepsilon) : [x, y] \subset \partial \Omega^{\eta, -}_{\varepsilon, \delta} \cap \partial \hat{O}^{\eta}_{\varepsilon, \delta} \right\},
\]
\[ B^{\eta, \pm}_{\varepsilon, \delta} := \bigcup_{j=1}^{I_{\varepsilon, \delta}^{\eta}} \partial_{\varepsilon, \delta}(\xi_j), \]
\[ B^{\eta, n}_{\varepsilon, \delta} := \{ (x, y) \in E_{\varepsilon}(\mu_{\varepsilon}) : [x, y] \subset \partial \hat{O}_{\varepsilon, \delta}^{\eta} \} \setminus \left( B^{\eta, -}_{\varepsilon, \delta} \cup B^{\eta, +}_{\varepsilon, \delta} \right). \]

By construction, the set of bonds \( \{x, y\} \) with \([x, y] \subset \partial \hat{O}_{\varepsilon, \delta}^{\eta} \) is given by the pairwise disjoint union of the bonds in the sets \( B^{\eta, -}_{\varepsilon, \delta}, B^{\eta, +}_{\varepsilon, \delta}, \) and \( B^{\eta, n}_{\varepsilon, \delta} \) so that

\[ \text{Per} \left( \hat{O}_{\varepsilon, \delta}^{\eta} \right) := \varepsilon \sharp B^{\eta, -}_{\varepsilon, \delta} + \varepsilon \sharp B^{\eta, +}_{\varepsilon, \delta} + \varepsilon \sharp B^{\eta, n}_{\varepsilon, \delta}. \] (3.17)

**Claim 3** \( \text{Per}(\hat{O}_{\varepsilon, \delta}^{\eta}) + \sum_{f \in S_{\varepsilon, \delta}^{\varepsilon}} (\text{Per}(f) - 3\varepsilon) \geq (1 + r(\eta)) \text{Per}_{\varphi_{\hat{O}_{\varepsilon, \delta}^{\eta}}}, \) where \( r(\eta) \to 0 \) as \( \eta \to 0. \)

We preliminarily notice that for every bond \( \{x, y\} \in B^{\eta, -}_{\varepsilon, \delta}, \)

\[ \varphi_{\hat{O}}([x, y]) \leq \frac{1}{1 + r(\eta)}. \] (3.18)

for some \( r(\eta) \to 0 \) as \( \eta \to 0. \)

Now we prove that

\[ \sum_{j=1}^{I_{\varepsilon, \delta}^{\eta}} \sum_{f \in S_{\varepsilon, \delta}^{\varepsilon}, f \subset \xi_j} (\text{Per}(f) - 3\varepsilon) \geq \sum_{j=1}^{I_{\varepsilon, \delta}^{\eta}} \frac{\varepsilon}{4} \sharp \partial_{\varepsilon, \delta}(\xi_j) = \frac{\varepsilon}{4} \sharp B^{\eta, +}_{\varepsilon, \delta}. \] (3.19)

Indeed, let \( f \in S_{\varepsilon, \delta}^{\varepsilon} \) with \( f \subset \xi_j \) for some \( j = 1, \ldots, I_{\varepsilon, \delta}^{\eta}. \) Then

\[ \text{Per}(f) - 3\varepsilon - \frac{\varepsilon}{4} \sharp \{ (x, y) \in \partial_{\varepsilon, \delta}(\xi_j) : [x, y] \subset \partial f \} \geq \frac{3}{4} \text{Per}(f) - 3\varepsilon \geq 0. \]

It follows that

\[ \text{Per}(f) - 3\varepsilon \geq \frac{\varepsilon}{4} \sharp \{ (x, y) \in \partial_{\varepsilon, \delta}(\xi_j) : [x, y] \subset \partial f \}, \]

which summing over \( f \in S_{\varepsilon, \delta}^{\varepsilon} \) with \( f \subset \xi_j \), implies that

\[ \sum_{f \in S_{\varepsilon, \delta}^{\varepsilon}, f \subset \xi_j} \text{Per}(f) - 3\varepsilon \geq \frac{\varepsilon}{4} \sum_{f \in S_{\varepsilon, \delta}^{\varepsilon}, f \subset \xi_j} \sharp \{ (x, y) \in \partial_{\varepsilon, \delta}(\xi_j) : [x, y] \subset \partial f \} = \frac{\varepsilon}{4} \sharp B^{\eta, +}_{\varepsilon, \delta}(\xi_j). \] (3.20)
where the equality is a consequence of the fact that if \( \{x, y\} \in \mathcal{P}^+(\xi_i) \) and \( f \subset \Omega^+ \), then \( \{x, y\} \) is not a bond of \( f \). By (3.20) and (3.15), and finally summing over \( j \), we deduce (3.19).

Now, we consider bonds \( \{x, y\} \in B^{\eta,n}_{\epsilon,\delta} \), and we notice that \( \{x, y\} \in \partial f \) for some (unique) \( f \subset \hat{\mathcal{O}}^\eta_{\epsilon,\delta} \setminus \bigcup_{j=1}^{J_{\epsilon,\delta}} \xi_j \) with \( f \in S^\#_{\epsilon,\delta} \). We prove that

\[
\sum_{f \in S^\#_{\epsilon,\delta}} (\text{Per}(f) - 3\epsilon) \geq \frac{\epsilon}{4} \# B^{\eta,n}_{\epsilon,\delta}. \tag{3.21}
\]

Indeed, let \( f \in S^\#_{\epsilon,\delta} \) with \( f \subset \hat{\mathcal{O}}^\eta_{\epsilon,\delta} \setminus \bigcup_{j=1}^{J_{\epsilon,\delta}} \xi_j \) and let \( \{x_1, y_1\}, \ldots, \{x_L, y_L\} \in B^{\eta,n}_{\epsilon,\delta} \) be such that \( \bigcup_{i=1}^{L} [x_i, y_i] = \partial f \cap \partial \hat{\mathcal{O}}^\eta_{\epsilon,\delta} \). Then, since \( \text{Per}(f) \geq 4\epsilon \), we have

\[
\text{Per}(f) - 3\epsilon - \frac{\epsilon}{4} L = \frac{3}{4} \text{Per}(f) + \frac{1}{4} (\text{Per}(f) - \epsilon L) - 3\epsilon \geq 0,
\]

which summing over \( f \) implies (3.21).

By (3.17), (3.18), (3.21), and (3.19), we can thus conclude

\[
\text{Per}(\hat{\mathcal{O}}^\eta_{\epsilon,\delta}) + \sum_{f \in S^\#_{\epsilon,\delta}} (\text{Per}(f) - 3\epsilon) \geq 4\epsilon \# B^{\eta,\epsilon}_{\epsilon,\delta} + 4\epsilon \# B^{\eta,\epsilon}_{\epsilon,\delta} + \sum_{f \in S^\#_{\epsilon,\delta}} (\text{Per}(f) - 3\epsilon)
\]

\[
+ \frac{5}{4} \# B^{\eta,n}_{\epsilon,\delta} + \frac{5}{4} \# B^{\eta,n}_{\epsilon,\delta}
\]

\[
\geq (1 + r(\eta)) \sum_{\{x, y\} \in B^{\eta,\epsilon}_{\epsilon,\delta}} \varphi_{\theta}([x, y]) + \frac{5}{4} \# B^{\eta,\epsilon}_{\epsilon,\delta} + \frac{5}{4} \# B^{\eta,\epsilon}_{\epsilon,\delta}
\]

\[
\geq (1 + r(\eta)) \sum_{\{x, y\} \in B^{\eta,\epsilon}_{\epsilon,\delta}} \varphi_{\theta}([x, y]) + \sum_{\{x, y\} \in B^{\eta,n}_{\epsilon,\delta} \cup B^{\eta,n}_{\epsilon,\delta}} \varphi_{\theta}([x, y])
\]

\[
\geq (1 + r(\eta)) \text{Per}_{\varphi_{\theta}}(\hat{\mathcal{O}}^\eta_{\epsilon,\delta}),
\]

where the third inequality is a consequence of the fact that \( \frac{5}{4} \geq \frac{2}{\sqrt{3}} = \max_{v \in S^1} \varphi_{\theta}(v) \), being \( S^1 \) the unitary sphere in \( \mathbb{R}^2 \).

**Claim 4** \( \lim_{\epsilon \to 0} \|1_{\hat{\mathcal{O}}^\eta_{\epsilon,\delta}} - 1_{\Omega_{L^1(\mathbb{R}^2)}} = 0 \). By (3.6) and (2.4), we get

\[
C \geq \sum_{f \in S^\#_{\epsilon,\delta}} (\text{Per}(f) - 3\epsilon) \geq 4\epsilon \# S^\#_{\epsilon,\delta}. \tag{3.23}
\]
Moreover, by the very definition of $S_{\varepsilon, \delta}^{\neq \Delta}$ in (3.8) and by the isoperimetric inequality, we have

$$|f| \leq \frac{\varepsilon^2}{4\pi \delta^2}$$

for every $f \in S_{\varepsilon, \delta}^{\neq \Delta}$. (3.24)

Furthermore, by assumption

$$\lim_{\varepsilon \to 0} |\Omega_{\varepsilon - \delta}^{\eta^+}| = 0,$$

which, combined together with (3.23) and (3.24), yields

$$|\Omega_{\varepsilon - \delta}^{\eta} | \Delta \hat{O}_{\varepsilon, \delta}^{\eta} | \leq \sum_{f \in S_{\varepsilon, \delta}^{\neq \Delta}} |f| + |\Omega_{\varepsilon - \delta}^{\eta^+}| \leq C \frac{\varepsilon^2}{4\pi \delta^2} + |\Omega_{\varepsilon - \delta}^{\eta^+}| \to 0,$$

whence the claim immediately follows.

**Conclusion:** (3.4) holds true. By Claims 1–3, we have

$$\varepsilon(\mathcal{E}_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \geq (1 + r(\eta))\text{Per}_{\tilde{\psi}_{\tilde{\theta}}}^{\eta^+}(\hat{O}_{\varepsilon, \delta}) + r(\delta),$$

which, by Claim 4, in view of the lower semicontinuity of the anisotropic perimeter with respect to the strong convergence in $L^1(\mathbb{R}^2)$, implies

$$\liminf_{\varepsilon \to 0} \varepsilon(\mathcal{E}_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \geq (1 + r(\eta))\text{Per}_{\tilde{\psi}_{\tilde{\theta}}}(\Omega) + r(\delta).$$

Then, (3.4) by sending $\eta \to 0$ and $\delta \to 0$.

Proof of (ii) The $\Gamma$-limsup inequality can be easily obtained as a consequence of (A.2) and (2.4). For the reader’s convenience, we briefly sketch the proof. By standard density arguments in $\Gamma$-convergence we can assume that $\Omega$ has a finite number $M$ of connected components with polyhedral boundary. Let $X_{\varepsilon}^{\tilde{\vartheta}}$ be the periodic lattice generated by $\varepsilon e^{i(\hat{\vartheta} - \frac{\pi}{2})}$ and by $\varepsilon e^{i(\hat{\vartheta} - \frac{\pi}{6})}$. We denote by $F_{\varepsilon}(X_{\varepsilon}^{\tilde{\vartheta}})$ the set of equilateral triangles with vertices in $X_{\varepsilon}^{\tilde{\vartheta}}$ and side-length equal to $\varepsilon$. Set

$$X_{\varepsilon} := \{ x \in f : f \in F_{\varepsilon}(X_{\varepsilon}^{\tilde{\vartheta}}), f \subset \Omega \}, \quad \mu_\varepsilon := \sum_{x \in X_{\varepsilon}} \delta_{x}, \quad \Omega_{\varepsilon} := \bigcup \{ f \in F_{\varepsilon}(X_{\varepsilon}^{\tilde{\vartheta}}) : f \subset \Omega \}.$$

Since $F_{\varepsilon}(X_{\varepsilon}) = F_{\varepsilon}^{\Delta}(X_{\varepsilon})$, by (2.4), we immediately have

$$\varepsilon(\mathcal{E}_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) = \text{Per}(\Omega_{\varepsilon}) + 3\varepsilon M.$$

Moreover one can trivially check that $\text{Per}(\Omega_{\varepsilon}) \to \text{Per}_{\tilde{\psi}_{\tilde{\theta}}}(\Omega)$ as $\varepsilon \to 0$, thus concluding the proof of (ii).

Finally, in this last part of the section, we briefly consider the case of additional confining forcing terms. Let
\[ F^g_\varepsilon(\mu) := \mathcal{E}_\varepsilon(\mu) + 3\mu(\mathbb{R}^2) + \frac{\sqrt{3}}{2\varepsilon} \int_{\mathbb{R}^2} g \, d\mu, \]

where \( g \in C^0(\mathbb{R}^2) \) with \( g(x) \to +\infty \) as \( |x| \to +\infty \).

**Corollary 3.3** Let \( \{\mu_\varepsilon\} \subset \mathcal{M} \) be such that \( F^g_\varepsilon(\mu_\varepsilon) \leq C_\varepsilon \). Then, up to a subsequence,

1. **Compactness for \( \mu_\varepsilon \)**: \( \varepsilon^2 \frac{\sqrt{3}}{2} \mu_{\varepsilon} \rightharpoonup^* 1_\Omega \) dx for some set \( \Omega \subset \mathbb{R}^2 \) with \( 1_\Omega \in SBV(\mathbb{R}^2) \). Moreover, \( \varepsilon^2 \frac{\sqrt{3}}{2} \mu_{\varepsilon}(\mathbb{R}^2) \to |\Omega| \).
2. **Compactness for \( \theta_\varepsilon \)**: \( \theta_\varepsilon(\mu_\varepsilon) \rightharpoonup \theta \) in \( SBV(\mathbb{R}^2) \), for some \( \theta = \sum_{j \in J} \theta_j 1_{\omega_j} \), where \( J \subset \mathbb{N}, \{\omega_j\} \) is a Caccioppoli partition of \( \Omega \), and \( \{\omega_j\} \subset (\frac{\pi}{3}, \frac{2\pi}{3}) \).
3. \( (\Gamma\text{-liminf inequality}) \) If \( \theta = \bar{\theta} 1_\Omega \) for some \( \bar{\theta} \in (\frac{\pi}{3}, \frac{2\pi}{3}) \), then
   \[ \liminf_{\varepsilon \to 0} \varepsilon F^g_\varepsilon(\mu_\varepsilon) \geq H^1(\partial^* \Omega) + \int_\Omega g \, dx. \] (4.25)
4. \( (\Gamma\text{-limsup inequality}) \) For every set \( \Omega \subset \mathbb{R}^2 \) of finite perimeter and for every \( \bar{\theta} \in (\frac{\pi}{3}, \frac{2\pi}{3}) \), there exists a sequence \( \{\mu_\varepsilon\} \subset \mathcal{M} \) satisfying (1) and (2) with \( \theta = \bar{\theta} 1_\Omega \) such that
   \[ \limsup_{\varepsilon \to 0} \varepsilon F^g_\varepsilon(\mu_\varepsilon) \leq H^1(\partial^* \Omega) + \int_\Omega g \, dx. \] (4.26)

**Proof** We briefly sketch the proof, the details are left to the reader. Items (1) and (2) are an easy consequence of Theorem 3.1 and of the fact that, in view of the coercivity assumption \( g(x) \to +\infty \) as \( |x| \to +\infty \), there is no loss of mass at infinity. Items (3) and (4) are consequences of Theorem 3.2, once noticed that the functionals \( F^g_\varepsilon(\mu) \) are nothing but the functionals \( \mathcal{E}_\varepsilon(\mu) + 3\mu(\mathbb{R}^2) \) plus the continuous perturbation \( \frac{\sqrt{3}}{2\varepsilon} \int_{\mathbb{R}^2} g \, dx \).

---

**4 Asymptotic Behaviour of Energy Minimizers**

In this section, we present some variational problems for which the behaviour of configurations that are asymptotically optimal in energy can be easily studied using Theorems 3.1 and 3.2.

### 4.1 Energy Bounds for Polycrystals

**Proposition 4.1** The following lower and upper bounds hold true.

1. **(Lower bound)** For all \( \{\mu_\varepsilon\} \subset \mathcal{M} \) satisfying (i) and (ii) of Theorem 3.1, we have
   \[ \liminf_{\varepsilon \to 0} \varepsilon (\mathcal{E}_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \geq \mathcal{H}^1(\partial^* \Omega) + \frac{1}{2} \mathcal{H}^1(\cup_{j \in J} \partial^* \omega_j \setminus \partial^* \Omega). \] (4.1)
(ii) \textbf{(Upper bound)} For every set $\Omega \subset \mathbb{R}^2$ of finite perimeter and for every $\theta \in SBV(\Omega; (\frac{\pi}{4}, \frac{3\pi}{2})$ there exists a sequence $\{\mu_\varepsilon\} \subset \mathcal{M}$ satisfying (i) and (ii) of Theorem 3.1 such that

$$\limsup_{\varepsilon \to 0} \varepsilon(\mathcal{E}_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \leq \sum_j \text{Per}_{\varphi_{\theta_j}}(\omega_j).$$

(4.2)

\textbf{Proof} We start by proving (i). Let $\delta \in (0, \frac{1}{4})$ and let $O_{\varepsilon,\delta}$ and $\Omega_{\varepsilon}$ be defined as in (3.9) and (3.7). By Claim 1 in the proof of Theorem 3.2 and by using that $\text{Per}_f(\mathcal{O}_\varepsilon) \geq 4\varepsilon$ for every $f \in F_{\varepsilon,\delta}^\Delta(\mu_\varepsilon)$, we have

$$\varepsilon(\mathcal{E}_\varepsilon(\mu_\varepsilon) + 3 \mu_\varepsilon(\mathbb{R}^2)) \geq \text{Per}(O_{\varepsilon,\delta}) + \frac{1}{4}\mathcal{H}^1(\partial \Omega_{\varepsilon,\delta} \cap \partial O_{\varepsilon,\delta}) + r(\delta),$$

where $r(\delta) \to 0$ as $\delta \to 0$. By arguing as in Claim 4 in the proof of Theorem 3.2, one can easily show that

$$\|1_{O_{\varepsilon,\delta}} - 1_{\Omega}\|_{L^1} \to 0 \quad \text{as } \varepsilon \to 0.$$  

(4.3)

Let $\bar{\mu}_\varepsilon$ be the Radon measure defined by

$$\bar{\mu}_\varepsilon(A) := \text{Per}(O_{\varepsilon,\delta}, A) + \frac{1}{4}\mathcal{H}^1((\partial \Omega_{\varepsilon,\delta} \cap \partial O_{\varepsilon,\delta}) \cap A) \quad \text{for every open set } A \subset \mathbb{R}^2.$$  

By (4.3) and by the lower semicontinuity of the relative perimeter, we have

$$\liminf_{\varepsilon \to 0} \bar{\mu}_\varepsilon(B_r(x)) \geq \text{Per}(\partial^* \Omega, B_r(x)) \quad \text{for every } x \in \partial^* \Omega \text{ and for every } r > 0.$$  

(4.4)

Let now $x \in (\partial^* \omega_j \cap \partial^* \omega_k) \setminus \partial^* \Omega$ for some $j, k \in \mathbb{N}$ with $j \neq k$ and let $r > 0$. By (A.1) we have

$$\liminf_{\varepsilon \to 0} \bar{\mu}_\varepsilon(B_r(x)) \geq \frac{1}{4}\text{Per}(\partial^* \omega_j, B_r(x)) + \frac{1}{4}\text{Per}(\partial^* \omega_k, B_r(x)).$$  

(4.5)

By (4.4) and (4.5) together with standard blow up arguments (4.1) follows.

Finally, we briefly sketch the proof of (ii). Again by standard density arguments in $\Gamma$-convergence, we can assume that the $\omega_j$'s are in a finite number $M$, have pairwise disjoint closures and have polyhedral boundaries. Then, denoting by $\mu^j_\varepsilon$ the measure constructed in (ii) of Theorem 3.2 for $\Omega = \omega_j$, it is easy to check that $\mu_\varepsilon := \sum_j \mu^j_\varepsilon$ satisfies (4.2).

\textbf{Remark 4.2} (The Read–Shockley formula) In view of the lower bound (4.1), the energy density at grain boundaries is larger than a positive constant which does not depend on the magnitude of the jump $[\theta]$ of the orientation function. Such an estimate holds true also for positive $\varepsilon$ (and actually (4.1) is derived from that just letting $\varepsilon \to 0$). From these lower bounds, the compactness properties of $\theta_\varepsilon$ follow, leading in the limit to a piecewise constant orientation.
In fact, (4.1) is in contrast with the celebrated Read–Shockley formula (Read and Shockley 1950), which predicts that the energy density at grain boundaries is proportional to $|\theta| \log(|\theta|)$. In this respect the grain boundary energy within the sticky disc model turns out to be higher than the one for real crystals, where elastic deformations together with edge dislocations decrease the number of atoms with wrong coordination number, thus relaxing the energy density to lower states.

A natural question is whether an energy lower bound in terms of the Read–Shockley energy density $|\theta| \log(|\theta|)$ would still provide a piecewise constant orientation in the limit. Indeed, well-known compactness properties for SBV functions would imply that $\theta \in \text{SBV}$ with $\nabla \theta \equiv 0$; nevertheless, these conditions (even under uniform bounds for the Read–Shockley energy) do not ensure that $\theta$ takes a countable number of values (Ambrosio et al. 2000, Example 4.24).

In conclusion, the sticky disc energy does not allow to properly model edge dislocations at grain boundaries; some quantitative analysis of richer semi-discrete models taking into account the competition between elastic effects and edge dislocations is provided in Lauteri et al. (2017) and Fanzon et al. (2018).

### 4.2 Single Crystals Versus Polycrystals

Next corollary establishes that among all empirical measures converging to a limit set with edges parallel to the Wulff shape, single crystals are energetically favourable.

**Corollary 4.3** Let $\bar{\theta} \in (\frac{\pi}{3}, \frac{2\pi}{3})$, and let $\Omega$ be a subset of $\mathbb{R}^2$ with finite perimeter such that $\nu(x) \in \{v_k, \bar{\theta}\}_{k=1,2,3}$ for $\mathcal{H}^1$-a.e. $x \in \partial^* \Omega$, where $v_{k,\bar{\theta}} = e^{i(\bar{\theta} - \frac{\pi}{2})} v_k$, with $v_k$ defined in (2.9).

Let $\varepsilon_n \to 0$ and $\{\mu_{\varepsilon_n}\} \subset \mathcal{A}$ be such that

$$\inf \liminf \varepsilon \left( E_\varepsilon(\lambda_{\varepsilon}) + 3 \lambda_{\varepsilon}(\mathbb{R}^2) \right) = \lim_{n \to \infty} \varepsilon_n \left( E_{\varepsilon_n}(\mu_{\varepsilon_n}) + 3 \mu_{\varepsilon_n}(\mathbb{R}^2) \right).$$  \hspace{1cm} (4.6)

Then, up to a subsequence, $\theta_{\varepsilon_n}(\mu_{\varepsilon_n}) \rightharpoonup \bar{\theta} \mathbb{1}_\Omega$ in $\text{SBV}_{\text{loc}}(\mathbb{R}^2)$, where $\theta_{\varepsilon_n}(\mu_{\varepsilon_n})$ is defined according with (2.7) (Fig. 3).

**Fig. 3** Single crystal
Proof By (3.5), it easily follows that \( \varepsilon_n (E_{\varepsilon_n} (\mu_{\varepsilon_n}) + 3 \mu_{\varepsilon_n} (\mathbb{R}^2)) \leq C \). By Theorem 3.1, we have that, up to a subsequence, \( \theta_{\varepsilon_n} (\mu_{\varepsilon_n}) \rightharpoonup \theta \) in \( \text{SBV}_{\text{loc}} (\mathbb{R}^2) \) for some \( \theta \in \text{SBV} (\Omega) \) with \( \theta = \sum_{j \in J} \theta_j 1_{\omega_j} \), where \( J \subseteq \mathbb{N} \), \( \{\omega_j\}_j \) is a Caccioppoli partition of \( \Omega \), and \( \{\theta_j\}_j \subset (\frac{\pi}{3}, \frac{2}{3} \pi) \). By (4.1), (4.6) and (3.5) we have

\[
\text{Per}_{\varphi_0} (\Omega) + \frac{1}{2} \mathcal{H}^1 (\cup_{j} \partial^* \omega_j \setminus \partial^* \Omega) = \mathcal{H}^1 (\partial^* \Omega) + \frac{1}{2} \mathcal{H}^1 (\cup_{j} \partial^* \omega_j \setminus \partial^* \Omega) \\
\leq \liminf_{n \to \infty} \varepsilon_n (E_{\varepsilon_n} (\mu_{\varepsilon_n}) + 3 \mu_{\varepsilon_n} (\mathbb{R}^2)) \\
= \inf_{\varepsilon^2 \frac{\sqrt{2}}{\lambda_1} \lambda_{\varepsilon} \rightharpoonup \mathbb{1}_\Omega} \liminf_{\varepsilon \to 0} \varepsilon (E_{\varepsilon} (\lambda_\varepsilon) + 3 \lambda_\varepsilon (\mathbb{R}^2)) \leq \text{Per}_{\varphi_0} (\Omega).
\]

We deduce that \( \frac{1}{2} \mathcal{H}^1 (\{\cup_{j} \partial^* \omega_j \setminus \partial^* \Omega\}) = 0 \), and hence \( \theta = \hat{\theta} 1_{\Omega} \) for some \( \hat{\theta} \in (\frac{\pi}{3}, \frac{2}{3} \pi) \). By (3.4) and (3.5), we deduce that

\[
\text{Per}_{\varphi_0} (\Omega) \leq \text{Per}_{\varphi_0} (\Omega) \leq \liminf_{n \to \infty} \varepsilon_n (E_{\varepsilon_n} (\mu_{\varepsilon_n}) + 3 \mu_{\varepsilon_n} (\mathbb{R}^2)) \\
= \inf_{\varepsilon^2 \frac{\sqrt{2}}{\lambda_1} \lambda_{\varepsilon} \rightharpoonup \mathbb{1}_\Omega} \liminf_{\varepsilon \to 0} \varepsilon (E_{\varepsilon} (\lambda_\varepsilon) + 3 \lambda_\varepsilon (\mathbb{R}^2)) \leq \text{Per}_{\varphi_0} (\Omega).
\]

We conclude that \( \text{Per}_{\varphi_0} (\Omega) = \text{Per}_{\varphi_0} (\Omega) \), which implies \( \hat{\theta} = \bar{\theta} \).

Remark 4.4 Using the minimality property of the measures \( \mu_{\varepsilon_n} \), one can prove that the compactness of the sequence \( \{\mu_{\varepsilon_n}\} \) stated in Corollary 4.3 in fact holds true in \( \text{SBV} (\mathbb{R}^2) \).

Next corollary provides a class of examples where the emergence of grain boundaries is rigorously derived by means of variational arguments.

Corollary 4.5 Let \( \vartheta_1, \vartheta_2 \in (\frac{\pi}{3}, \frac{2}{3} \pi) \) with \( \vartheta_1 \neq \vartheta_2 \) and, given \( \tau \in \mathbb{R}^2 \), set

\[
\Omega_{\tau} := W_{\vartheta_1} \cup (W_{\vartheta_2} + \tau), \quad m(\tau) := |W_{\vartheta_1} \cap (W_{\vartheta_2} + \tau)|. \tag{4.7}
\]

Then, there exists \( \bar{m} = \bar{m} (\vartheta_1, \vartheta_2) \) such that, whenever \( m(\tau) \leq \bar{m} \) the following holds:

Let \( \varepsilon_n \to 0 \) and \( \{\mu_{\varepsilon_n}\} \subset \mathcal{A} \) be such that

\[
\inf_{\varepsilon^2 \frac{\sqrt{2}}{\lambda_1} \lambda_{\varepsilon} \rightharpoonup \mathbb{1}_{\Omega_{\tau}}} \liminf_{\varepsilon \to 0} \varepsilon (E_{\varepsilon} (\lambda_\varepsilon) + 3 \lambda_\varepsilon (\mathbb{R}^2)) = \lim_{n \to \infty} \varepsilon_n (E_{\varepsilon_n} (\mu_{\varepsilon_n}) + 3 \mu_{\varepsilon_n} (\mathbb{R}^2)) .
\]

Then, up to a subsequence, \( \theta_{\varepsilon_n} (\mu_{\varepsilon_n}) \rightharpoonup \theta \) in \( \text{SBV}_{\text{loc}} (\mathbb{R}^2) \), for some \( \theta = \sum_{j \in J} \theta_j 1_{\omega_j} \) in \( \text{SBV} (\mathbb{R}^2) \), where \( J \subseteq \mathbb{N} \), \( \{\omega_j\}_j \) is a Caccioppoli partition of \( \Omega_{\tau} \), and \( \{\theta_j\}_j \subset (\frac{\pi}{3}, \frac{2}{3} \pi) \). Moreover, the function \( \theta \) is not constant, i.e. \( \# J \geq 2 \) (Fig. 4).
Proof Notice that we can always write $\Omega_\tau = \omega_1 \cup \omega_2$, with $\omega_1$ and $\omega_2$ open disjoint set such that $S := \partial \omega_1 \cap \partial \omega_2$ is a segment and $\partial \omega_j \setminus S \subset W_{\theta_j}$ for $j = 1, 2$. Moreover, there exists a modulus of continuity $l(m) \to 0$ as $m \to 0$ such that $H^1(S) \leq l(m)$ with $m = m(\tau)$ defined in (4.7).

By (4.2), there exists a sequence $\{\bar{\lambda}_\varepsilon\}$ such that

$$\lim_{n \to \infty} \varepsilon_n (E_{\varepsilon_n}(\mu_{\varepsilon_n})) + 3\mu_{\varepsilon_n}(\mathbb{R}^2)) = \inf_{\varepsilon \to 0} \varepsilon (E_{\varepsilon}(\bar{\lambda}_\varepsilon) + 3\bar{\lambda}_\varepsilon(\mathbb{R}^2))$$

$$\leq \limsup_{\varepsilon \to 0} \varepsilon (E_{\varepsilon}(\bar{\lambda}_\varepsilon) + 3\bar{\lambda}_\varepsilon(\mathbb{R}^2)) \leq \sum_{j=1}^2 \mathop{\text{Per}}_{\phi \theta_j}(\omega_j) \leq \sum_{j=1}^2 \mathop{\text{Per}}(W_{\theta_j}) + c l(m).$$

(4.8)

for some $c < \infty$. In particular, by (3.1), $\theta_{\varepsilon_n}(\mu_{\varepsilon_n}) \rightharpoonup \theta$ in $\text{SBV}_{\text{loc}}(\mathbb{R}^2)$ for some $\theta \in \text{SBV}(\Omega)$ with $\theta = \sum_{j \in J} \theta_j 1_{\omega_j}$, where $J \subseteq \mathbb{N}$, $\{\omega_j\}_j$ is a Caccioppoli partition of $\Omega$, and $\{\theta_j\}_j \subset (\frac{\pi}{2}, \frac{3\pi}{2}]$. It remains to prove that, for $m(\tau)$ small enough, $\theta$ is not constant. If $\theta = \bar{\theta} \mathbb{1}_\Omega$, for some $\bar{\theta} \in (\frac{\pi}{2}, \frac{3\pi}{2}]$, then, by (3.4), we have

$$\lim_{n \to \infty} \varepsilon_n (E_{\varepsilon_n}(\mu_{\varepsilon_n}) + 3\mu_{\varepsilon_n}(\mathbb{R}^2)) \geq \mathop{\text{Per}}_{\bar{\theta}}(\Omega_\tau)$$

$$\geq \sum_{j=1}^2 (1 + p(\bar{\theta} - \theta_j))H^1(\partial \Omega_\tau \cap \partial W_{\theta_j}) \geq \sum_{j=1}^2 (1 + p(\bar{\theta} - \theta_j))\mathop{\text{Per}}(\partial W_{\theta_j}) - r(m).$$

(4.9)

for some moduli of continuity $p, r : [0, +\infty) \to \mathbb{R}$ which are continuous, vanishing at zero and strictly positive elsewhere. Clearly, (4.8) and (4.9) are not compatible for $m$ smaller than some $\bar{m}$ depending only on $\bar{\theta}_1$ and $\bar{\theta}_2$. \qed
Appendix: Optimal Tessellations of the Plane

It is well known that the plane can be tessellated by regular polygons whose associated lattices are of Bravais type; more precisely, by equilateral triangles and squares.

Fix one of such regular polygons $p$ and assume that the edges of $p$ have length equal to one. Let $I = (\Theta_1, \Theta_2]$ be a given interval, representing the family of orientations of $p$, and satisfying suitable properties listed below. Set $\Theta_{av} := \frac{1}{2}(\Theta_1 + \Theta_2)$, and $p_{\theta} := e^{i(\theta - \Theta_{av})} p$ for all $\theta \in \tilde{I}$. The required properties of $I$ are that $0 \in I$, $\mathcal{H}^1(\partial(p_{\Theta_1} + \tau) \cap \partial p_{\Theta_2}) = 1$ for some $\tau \in \mathbb{R}^2$, $\mathcal{H}^1(\partial(p_{\alpha_1} + \tau) \cap \partial p_{\alpha_2}) = 0$ for every $\alpha_1, \alpha_2 \in I$ and for every $\tau \in \mathbb{R}^2$.

For instance, we can choose $I = (\frac{\pi}{3}, \frac{2}{3}\pi]$ if $p$ is the equilateral triangle and $I = (\frac{\pi}{4}, \frac{3}{4}\pi]$ if $p$ is the square.

Let $\phi$ and $\phi_\theta$ be defined as in (2.8) and (2.10), with the vectors $v_i$ in (2.9) replaced by the normals $v_k$ to $\partial p$, i.e. the unitary vectors orthogonal to the edges of $p$.

For every $\epsilon > 0$ set

$$F_\epsilon := \{ \epsilon p_{\theta} + \tau : \theta \in I, \tau \in \mathbb{R}^2 \}.$$ 

Notice that for all $f \in F_\epsilon$ there exists a unique $\theta = \theta(f)$ such that $f = \epsilon p_{\theta}$ up to a (still unique) translation.

**Lemma A.1** Let $\{v_k\}$ be the set of the normals to $\partial p$. There exists a modulus of continuity $r(\eta)$ with the following property. Let $\phi^n : S^1 \rightarrow \mathbb{R}$ be defined by

$$\phi^n(v) := \begin{cases} 1 & \text{if } \max_k |v \cdot v_k| \geq 1 - \eta; \\ \phi(v) & \text{otherwise.} \end{cases}$$

Let $\{\Omega_\epsilon\}$ be a sequence of sets of finite perimeter such that $\1_{\Omega_\epsilon} \rightarrow 1_{\Omega} \text{ in } SBV_{\text{loc}}(\mathbb{R}^2)$ for some set $\Omega$ of finite perimeter. Then

$$\liminf_{\epsilon \rightarrow 0} \int_{\partial^+ \Omega_\epsilon} \phi^n(v) \, d\mathcal{H}^1 \geq (1 + r(\eta)) \text{Per}_{\phi}(\Omega).$$

**Proof** There exists $c(\eta) > 0$ with $c(\eta) \rightarrow 1$ as $\eta \rightarrow 0$ such that $|\phi^n(v) - \phi(v)| \leq c(\eta)$ for all $v \in S^1$. Therefore the lemma is an easy consequence of the lower semicontinuity of the $\phi$-perimeter $\text{Per}_{\phi}$. \hfill \Box

In what follows, for every $\epsilon > 0$, we denote by $\Phi_\epsilon$ the set of the families of faces $H_\epsilon \subset F_\epsilon$ whose interiors are pairwise disjoint. Moreover, we set

$$O_\epsilon := \left\{ \Omega \subset \mathbb{R}^2 : \Omega = \bigcup_{f \in H_\epsilon} f, \text{ for some } H_\epsilon \in \Phi_\epsilon \right\}.$$ 

Now, we prove a $\Gamma$-convergence result.
Theorem A.2 The following $\Gamma$-convergence result holds true.

(a) (Compactness) Let $H_\varepsilon \in \Phi_\varepsilon$ and set

$$
\Omega_\varepsilon := \bigcup_{f \in H_\varepsilon} f, \quad \theta_\varepsilon := \sum_{f \in H_\varepsilon} \theta(f) 1_f.
$$

Assume that $\text{Per}(\Omega_\varepsilon) \leq C$. Then, up to a subsequence, $\|\Omega_\varepsilon\| \to \|\Omega\|$ in $SBV_{\text{loc}}(\mathbb{R}^2)$ for some set $\Omega$ of finite perimeter. Moreover, $\theta_\varepsilon \to \theta$ in $SBV_{\text{loc}}(\mathbb{R}^2)$, for some $\theta = \sum_{j \in J} \theta(j) 1_{\omega_j}$ in $SBV(\Omega)$, where $J \subseteq \mathbb{N}$, $\{\omega_j\}_j$ is a Caccioppoli partition of $\Omega$, and $\{\theta(j)\}_j \subset I$.

(b) ($\Gamma$-liminf inequality) Let $H_\varepsilon, \Omega_\varepsilon, \theta_\varepsilon, \Omega, \theta$ be as in (a), and let $A$ be a an open set. Then

$$
\liminf_{\varepsilon \to 0} \text{Per}(\Omega_\varepsilon, A) \geq \sum_{j \in J} \text{Per}_{\phi_{\theta(j)}}(\omega_j, A). \tag{A.1}
$$

(c) ($\Gamma$-limsup inequality) For every set $\Omega \subset \mathbb{R}^2$ of finite perimeter and for every $\theta \in SBV(\Omega)$, there exists a sequence $\{H_\varepsilon\}$ satisfying the claim in (a) such that

$$
\limsup_{\varepsilon \to 0} \text{Per}(\Omega_\varepsilon) \leq \sum_{j \in J} \text{Per}_{\phi_{\theta(j)}}(\omega_j). \tag{A.2}
$$

Proof Proof of (a) By the very definition of $\theta(f)$, we have that $\|\theta_\varepsilon\|_{L^\infty} \leq \Theta_2$. Moreover, by the uniform bound on $\text{Per}(\Omega_\varepsilon)$, we obtain that $\mathcal{H}^1(S_{\theta_\varepsilon}) \leq C$. It follows that $\|\theta_\varepsilon\|_{BV} \leq C$ for some constant $C \in \mathbb{R}$ independent of $\varepsilon$. Then the claim follows from Corollary 2.2.

Proof of (b) For every $\vartheta \in I$ let $H_\varepsilon(\vartheta) := \{f \in H_\varepsilon : \theta(f) = \vartheta\}$, and set $\Omega_\varepsilon(\vartheta) := \bigcup_{f \in H_\varepsilon(\vartheta)} 1_f$. Notice that if $\vartheta_1 \neq \vartheta_2$, then

$$
\text{Per}(\Omega_\varepsilon(\vartheta_1) \cup \Omega_\varepsilon(\vartheta_2), A) = \text{Per}(\Omega_\varepsilon(\vartheta_1), A) + \text{Per}(\Omega_\varepsilon(\vartheta_2), A),
$$

for every open bounded set $A \subset \mathbb{R}^2$. It follows that there exists an at most countable set of indices $J$ and a set $\{\vartheta_n\}_{n \in J} \subset I$ such that $\Omega_\varepsilon(\vartheta_n) \neq \emptyset$ for every $n \in J$ and

$$
\text{Per}(\Omega_\varepsilon, A) = \sum_{n \in J} \text{Per}(\Omega_\varepsilon(\vartheta_n), A) \text{ for every open bounded set } A \subset \mathbb{R}^2.
$$

Let $M \in \mathbb{N}$ and consider $\vartheta_1, \ldots, \vartheta_M \in J$. Let $\eta > 0$ be such that

$$
|\vartheta_i - \vartheta_j| > \eta \text{ for all } 1 \leq i < j \leq M.
$$

Moreover, for every $1 \leq i \leq M$ set $I_{\varepsilon,i}^\eta := \{\vartheta \in I : |\vartheta - \vartheta_i| < \frac{\eta}{2}\}$, and

$$
\Omega_{\varepsilon,i}^\eta := \bigcup_{\vartheta \in I_{\varepsilon,i}^\eta} \Omega_\varepsilon(\vartheta).
$$
Then, \( \mathbb{1}_{\Omega_i^n} \to \mathbb{1}_{\omega_i} \) in \( L^1_{\text{loc}}(\mathbb{R}^2) \), with
\[
\Omega_i^n := \bigcup_{j \in J : |\theta_j - \theta_i| \leq \frac{\eta}{2}} \omega_j.
\]
Trivially, for every \( i = 1, \ldots, M \) we have that \( \Omega_i^n \to \omega_i \) in \( L^1_{\text{loc}}(\mathbb{R}^2) \) as \( \eta \to 0 \) and \( |\theta_i - \theta_i| \leq \frac{\eta}{2} \). By Lemma A.1, we deduce that for every open bounded set \( A \) it holds
\[
\liminf_{\varepsilon \to 0} \text{Per}(\Omega^n, A) \geq \sum_{i=1}^M \liminf_{\varepsilon \to 0} \text{Per}(\Omega^n, A) \geq (1 + r(\eta)) \sum_{i=1}^M \text{Per}(\omega_i, A).
\]
Letting first \( \eta \to 0 \) and then \( M \to +\infty \), we deduce the \( \Gamma \)-liminf inequality (b).

**Proof of (c)** Since partitions with polyhedral boundary are dense (see Braides et al. 2017), by standard density arguments in \( \Gamma \)-convergence we can assume that \( \omega_i \) are polygons. In this case, the construction of a recovery sequence satisfying (A.1) follows by arguing as in the proof of (4.2).

For \( \varepsilon > 0 \), we can define the following functional
\[
\text{Per}_\varepsilon(\Omega) = \begin{cases} 
\text{Per}(\Omega) & \text{if } \Omega \in \mathcal{O}_\varepsilon, \\
+\infty & \text{otherwise}.
\end{cases}
\]
We state the following corollary which is a direct consequence of Theorem A.2.

**Corollary A.3** The functionals \( \text{Per}_\varepsilon \) \( \Gamma \)-converge, with respect to the convergence in \( L^1_{\text{loc}}(\mathbb{R}^2) \) of characteristic functions, to the functional \( \text{Per}_0 \) defined by
\[
\text{Per}_0(\Omega) := \min \left\{ \sum_{j \in J} \text{Per}(\omega_j) : \sum_{j \in J} \mathbb{1}_{\omega_j} \in \text{SBV}(\Omega), \right. \\
\left. \left\{ \omega_j \right\}_{j} \text{ is a Caccioppoli partition of } \Omega, \left\{ \theta_j \right\} \subset I \right\},
\]
for all sets \( \Omega \) with finite perimeter.

Clearly, we have the following inequality, valid for all sets \( \Omega \) with finite perimeter:
\[
\text{Per}_0(\Omega) \leq \min_{\theta \in I} \text{Per}_{\psi_0}(\Omega). \tag{A.3}
\]

The considerations in Sect. 4.2 can be easily extended to the functionals \( \text{Per}_\varepsilon \) and \( \text{Per}_0 \). In particular, there exist sets \( \Omega \) such that the inequality in (A.3) is strict and, on the other hand,
\[
\min_{\Omega : |\Omega| = m} \text{Per}_0(\Omega) = \sqrt{m} \text{Per}(W_\psi),
\]
where $W_\varphi$ is the Wulff shape which solves the isoperimetric problem corresponding to the anisotropy $\varphi$, among sets with unit area. Moreover, letting $\Omega_\varepsilon$ be minimizers of

$$\min_{\Omega : |\Omega| = m} \text{Per}_\varphi(\Omega),$$

it follows that, up to rotations and translations, $\Omega_\varepsilon$ converge to $\sqrt{m} W_\varphi$ in the $L^1$-topology.

**Remark A.4** The results stated in Theorem A.2 can be extended also to the case of the unitary hexagonal tessellation in the following manner. First of all we notice that, in this case, the corresponding lattice is the honeycomb one which is purely complex (in the triangular and square cases the corresponding lattices are of Bravais type). More precisely, the unitary honeycomb lattice is given by $\mathcal{L}_H = \mathcal{L}_T \cup (\mathcal{L}_T + e_1)$ where $\mathcal{L}_T$ is the triangular lattice generated by the vectors

$$w_1 = \sqrt{3} e^{i \pi / 6}, \quad w_2 = \sqrt{3} e^{i \pi / 2}.$$

Let $\tilde{\varphi}$ be the Finsler norm defined as in (2.8) but with the vectors $v_i$ replaced by

$$v_1 = e^{i \pi / 3}, \quad v_2 = e^{i \pi}, \quad v_3 = e^{i 2 \pi / 3}.$$

Then, set $\varphi := \frac{2}{\sqrt{3}} \tilde{\varphi}$ and consider the crystalline perimeter

$$\text{Per}_\varphi(G) := \int_{\partial^* G} \varphi(\nu) \, d\mathcal{H}^1$$

for every set $G$ of finite perimeter. (A.4)

The factor $\frac{2}{\sqrt{3}}$ encodes the fact that one generator of $\mathcal{L}_T$ (whose length equals to $\sqrt{3}$) corresponds to two unitary bonds in $\mathcal{L}_H$. The generalizations to $\varphi_\theta$ and $\text{Per}_{\varphi_\theta}$ are obvious. With formula (A.4) and $\text{Per}_{\varphi_\theta}$ in hand the $\Gamma$-convergence statement in Theorem A.2 can be easily proven also in this case with minor changes in the proof.
